**Anchor for Railway Carriages, &c.**, 450  
**Anthracite Coal**, smelting iron ore with, 508  
**Appeal to the citizens of Oneida county**, 546; of Professor Silliman, 669  
**Arithmetic by Machinery**, 484  
**Arnold's Machine for making Twisted Raving**, 699  
**Asmodius**, 550  
**Assassins**, history of, 526  
**Auburn**, growth and prospects of, 546  
**Audubon, Mr.**, 606  
**Austin, San Felipe de**, 825  
**Autumn Hens**, 651  
**Avery's Rotary Steam Engine**, 513  
**Average Duration of Life**, 622  
**Axle Railroad**, 510; **Vibrating**, bad tendency of, 611; **Bearing for carriages**, greasing of, 729

## B.

**Babbage on the Economy of Manufactures**, 598  
**Bachmann's Frame for Railroad Cars**, and other Carriages, 824  
**Badnal, J. S.**, on Undulating Railways, 594  
**Back, Capt.**, 524  
**Balloon communication between London and Paris**, 633; **Susceptible of direction**, 507; **Ascension of**, 559  
**Baltimore**, extension of, 465  
**Barometrical Measurement**, 830  
**Beam Compass**, description of, 645  
**Bedstead**, Relief, 700  
**Bee**, mathematical instinct of, 649  
**Bement's Improved Cultivator**, 488  
**Bergin's Patent Railway Buffing-Apparatus**, 790  
**Birchard's Warming and Ventilating Process**, 517  
**Biscuits**, machine for making, 698  
**Blue, Prussian**, on Woollens, 597  
**Boat Race**, 614  
**Boston**, to by day-light, 433  
**Boston and Norwich Railroad Company**, 557; and **Lowell Railroad**, 740; and **Providence Railroad**, 497; and **Worcester Railroad**, 457  
**Bristol and Gloucestershire Railway**, 644  
**Bricks**, moulding, patent for, 535  
**Bridges**, Elliptical-framed, by Lieut. Geo. W. Long, 690; building, on Col. Long's plan, 691; across the Illinois River, 457  
**Brownsville Internal Improvement Convention**, 758  
**Bruges Stove**, 517

**Budding of Trees**, 425, 441  
**Buffalo Harbor**, improvement in, 470  
**Burden's Steamboat**, 433; **Spikes**, 484  
**Burning of Steamboat Walk-in-the-Water**, 792  
**Business**, increase of, 577

## C.

**Cadets**, List of, and Orders respecting, 444  
**Canal**, Enlargement of the Erie, 423; from Columbia to the Chesapeake, 433; **Celebration**, 470; **Olean**, 529; **Passage**, quick, No. 27, 417; **Packets**, No. 27, 417; **Chenango**, 423; **Breach of at Byron**, 481; **Black River**, 657; **Completed**, 425; **Board**, Letter, 692; **Around the Falls of Niagara**, 725; **Meeting**, 610, 741; **Intelligence**, 760, 778; **Ship**, 593; **Sandy and Beaver**, 760; **Summary**, No. 27, 423; **Steamboat**, 423, 470; **Tolls**, 457, 470, 568, 570; **Union**, 466; **Welland**, 696; **Wabash and Erie**, riots on, 549  
**Cars**, Railroad, Mr. Herron's improvements in, 823; **Bachmann's Frame for**, and other carriages, 824  
**Card, a**, to the subscribers and friends of the Railroad Journal, &c., 832  
**Cast-Iron Water Pipes**, on the obstruction of, 580  
**Census of New-York**, 702  
**Charleston and Cincinnati Railroad**, 774  
**Chemical Examination of Petroleum**, 565  
**Cheese Press**, 698  
**Chesapeake and Delaware Canal**, deep cut in, 497  
**Chimneys**, Anti's Improved, 550  
**China**, Improved Hogs, 617  
**Chicago**, Letter from, 419  
**Chicago**, Sales of Land in, 478  
**Circular Spring Wheels**, Adams', 514; **Letter to the Consumers of Hops**, 522  
**City of Philadelphia**, 601; **Affairs**, 610  
**Civilization**, progress of, 660  
**Cleveland and Cincinnati Railroad**, 758  
**Clock**, Improved, 697  
**Clover Seed**, saving, 551  
**Clute, Peter**, specification, 424  
**C. M. H. Notices of Gardens**, 424  
**Coal Deposits**, 727  
**Codner Park Works**, 435  
**College**, Gerard, 524; **Washington**, 525  
**Comet**, 594; **contact of**, 585  
**Commerce of Oswego**, 497  
**Comfort to Travellers**, 753  
**Concord, N. H.**, and **Hartford, Vt.**, Railroad, 577  
**Concretion**, new, produced on Iron, 581  
**Conflagration**, losses by the, 785  
**Construction of curves for arches**, 593  
**Constantine, Grand Duke**, 573  
**Convention, Railroad**, 449, 506; **Internal Improvement**, 506, 727, 769; at **Brownsville**, 753; at **Albany**, 796; **Agricultural**, 826, 827  
**Cotton Yarn**, turns of twist in, 487; from **Algiers**, 478  
**Cooking by Gas**, 486, 519; **food for Domestic Animals**, 617  
**Croton River**, 646

**Currants**, 558; **Jelly and Wine**, 539  
**Cultivator**, Bement's Improved, 488

## D.

**Daglish's Prize Rails and Pedestals**, 562  
**Davis, Phineas**, notice of, 664  
**Dayton and Cincinnati Railroad**, 758  
**Deep cut in the Chesapeake and Delaware Canal**, 697  
**Defence, National**, 636  
**De Graaff**, communication from, 593  
**Delineator, Simple Perspective**, 745  
**Description of Freyburg Suspension Bridge**, 416  
**Dew, Thomas R.**, on the causes and effects of fluctuations, 436  
**Disasters on the Lakes**, 767  
**Discoveries in the Moon**, 553  
**Distances**, New Method of Measuring, 518  
**Diving Dress**, description of, by C. Conderdt, 745  
**Division of Labor**, evil effects of, 583  
**Domestic Intelligence**, 422  
**Draw Bridge**, Hopkins' Cast-Iron, 417  
**Drill**, Improved, 697  
**Dry Dock**, Floating, 544  
**Dufrenoy, M.**, Report of, 436, 453  
**Durable Whitewash**, 659  
**Durham Short Horns**, great importation of, 749  
**Dessumier's Natural History**, 522

## E.

**Earthquake at Kaissirick**, 792  
**Education, Female**, 586; **State of in England**, 683  
**Elliptical-frame Bridge**, 690  
**Engine, Rotary**, Avery's, 513; **New Steam**, 659; **Locomotive**, 823; **Mr. L. E. Miller's Patent for increasing the adhesion of the hind wheels of**, 824  
**Engineers**, Queries to, 391  
**Enlargement of Erie Canal**, 423, 529, 546, 631, 726  
**Evidence on the Great Western Canal**, 726  
**European Intelligence**, 422, 463, 478, 492, 509, 539, 572, 587  
**Evidence of Joshua Field, Esq.**, on Steam Navigation, 530  
**Expedition to the Euphrates**, 563  
**Experiments on the Preservation of Sheet Iron from Rust**, 564; to force the transverse inclination of conical wheels, 613  
**Extract from the Report of Dr. Birkbeck**, 662; from the Letter of A. W., 750; from Com. Porter, 461

## F.

**Factories**, Steam, 423  
**Fairman, Simon**, Machine for Making Wrought Nails, 607  
**Fair of the American Institute**, 697; **Mechanics' Institute**, 455; **Agricultural, and Horticultural Societies**, 826  
**Fall of a Public Store**, 540  
**Ferries and Avenues**, 470  
**Female Education**, 586  
**Finances of Connecticut**, 429  
**Fireman's Guide**, 695

Folger's Floating Dry Dock, 544  
Foot Railroads, 417  
Forest Trees of America, 442, 457  
Forge, Silversmith's Portable, 473  
Fort Leavenworth, 423  
Franklin Institute, conversation meeting of, 534; Doctor, letter to, 535  
Frame for Railroad Cars and other Carriages, Bachmann's, 824  
Fruit, large, 601  
Funeral of the victims of July 28th, 587

G.

Galina Land Office, 591  
Garden, Kitchen, management of a, 828  
Gas, cooking by, 519; application of to economical and domestic purposes, 519  
Generating Steam, 424  
Gener. Don Thomas, death of, 559  
Gerard College, 525  
Gibbs' Improved Corn, 520; improvement in carriages and carriage wheels, 742  
Glass, improvement in the manufacture of, 519; plated, 418  
Glasgow, steam engines in, 549  
Gloucester Cheese, 487  
Gold Leaves, 478; Gold, 526  
Gooseberry, 538  
Grand Junction Railway, 591, 497; Report of Engineer of, 498  
Grain-worm, 523  
Great Importation of Durham Short Horns, 649  
Grimes, William C., Patent for making Bricks, 535; for making Wrought Nails, &c., 567; for making Tacks, 582

H.

Hamilton's Machine for Sawing down Trees, 699  
Harkness' Plan for constructing Railroads, 710  
Hemans, Mrs., notice of, 444; personal recollections of, 475  
Hogs, China, improved, 617  
Honorable Pledge, 590  
Hops, circular to the consumers of, 522  
Hopkins' Cast-Iron Draw Bridge, 714  
Horticultural Societies and Agricultural Fairs, 826  
Hunt, Walter, Patent Forest Saw, 697  
Hunter's Stone-Planing Machine, 534  
Hydraulic Blast Wheel, 582  
Hydrometer, new, 550  
Hydrostatic pressure on the eyes of whales, 466

I.

Illinois, 568; River, bridge across, 457  
Important Decision, 632, 690  
Improvement in Chisels for cutting Stone, 534; Mechanical, 660; in Buffalo Harbor, 470  
Improved Short Horns, 488; Clock, 697; Theodolite, 697; Drill, 697; Draught of the Hull of a Steamboat, 549; Chimneys, 550  
Inclined Planes, 595  
Index for cutting teeth in gear wheels, 661  
Indian corn, ruta бага injurious to, 519  
Influence of professions on morality, 622  
Inquiries previous to commencing manufactures, 599  
Intemperance, 671  
Internal Improvement Convention, 727; at Brownsville, 759; at Utica, 769, 771; at Albany, 786  
Iron, experiments on the preservation of, 564; malleable, experiments on, 418, 419, 451; works, Speedwell, 473  
Island of New-York, 696  
Isthmus of Darien, 423

J.

Johnson, E. F., letter from, 630

Jones' madder crop, 520  
Joseph's, St., Florida, 633  
Junction of the Rhine and Danube, 452

K.

King William and the Canada Commissioners, 509  
Kitchen Garden, management of a, 828  
Knox Cave, 654  
Koskiusko, monument and death of, 653

L.

Laboring classes in Europe, 800  
Lady's Slipper, 522  
Lands sold for taxes, 665  
Large Fruit, 601  
Last of the Tea-Party, 423  
Law of Partners, 423  
Lead, 494  
Lectures of Dr. Birkbeck, extract from, 662; on Printing, 637  
Legends of a Log Cabin, 667; of Count Julian, 552  
Leslie, Mr., 608  
Letter to the committee on the proposed Hudson and Ontario Canal, 626; to the Canal Board, 692; to the Secretary of State of the United States, 735, 733; from J. S. Williams, 788; from John B. Jarvis and others, relative to Ship Canal, &c., 692; from J. Thomas, 417; from Chicago, 418; extract of from Apalachicola, 423; from Red River, 424  
Liquids, resistance of, &c., 507  
Literary Notices, 419, 444, 459, 475, 491, 570, 602, 619, 634, 650, 666, 743, 763, 798  
Liverpool and Manchester Railroad, 643  
Lock gates for canals, 656; new improved, 446  
Locomotive Engines, spark catcher for, 436, 432; E. K. Dod's Six-wheeled, 822; Increasing the adhesion of the hind wheels of, 825  
Locomotion, Principles of Railway, 823  
Long Levels, 724  
Lucifer Matches, 568, 592  
Losses by the late conflagration, 785

M.

Machine for making wrought nails, 607; for making stoves, 697; for sawing and jointing shingles, 693; for mortising, 698; for making twisted raving, 699; for making biscuit, 698  
Madder crop, 520  
Malleable Iron, experiments on the longitudinal extension of, 419, 451  
Management of a Kitchen Garden, 823  
Manganese, 597  
Manufactures of cotton in the United States, 601; American, 475  
Manufacturing Power, 546  
Marshall, Chief Justice, character and obituary of, 427  
Mazeppa Car, 577  
Measurement, barometrical, 830  
Mr. Cutchon, William, death of, 491  
Mechanics in Salem, 568  
Mechanical Improvements, 660  
Mechanics' Institute, Fair of, 555, 712  
Message of the President, 773  
Meteorological Table, 424, 576, 600, 826  
Meeting of the Inhabitants of Williamsburg, 659  
Meteoric Display, 728  
Metallic Cement, new, 659  
Men and Manners in America, 602  
Mexico, 830  
Michaux, list of forest Trees, 442, 457  
Midshipmen, list of, 429  
Migration of Animals, 574  
Monument to Perry, 696  
Moulding Bricks, 535  
Moving Plant, 623  
Mowing Machine, 696

N.

Natural History, Desumier's, 522  
National Defence, 630  
Navigating the Ocean by Steam, 614  
New Hydrometer, 550; Metallic Cement, 659; Method of Measuring Distances, 518  
Newton, G. S., death of, 581  
New Steam Engine, 659  
Novelty Works, 660  
Night Ferry Boat, 462  
Norwich Silk Company, 523  
Noble's Improvement in the application of Steam, 743  
Notice of Gardens and Nurseries in New-York and Philadelphia, 551, 568; of the Seasons, by H. C., 747, 761  
Number of Engineers, 482  
Nurseries of Shaw and Thorburn, 552

O.

Obstruction of Cast-Iron Water Pipes, 586  
Old Men and Women, 487  
Omnibuses, 605  
On the Practice of the Blow Pipe, 743  
On the Resistance of Fluids, 744  
Opening the Port of Singapore, 639  
Oswego, commerce of, 497; Sale of Lands at, 670

P.

Packets, canal, new line of, 417; Ship, Sheffield, 559  
Patent Churn, 598; Laws, 523  
Peach Trees, 426  
Pennsylvania Canal Tolls, 457  
Perilous Balloon Ascension, 559  
Penny, English, placed at interest, 487  
Petroleum, chemical examination of, 565  
Pic Nic, 750  
Pittsburg, 497  
Plantou, Dr., mode of propelling boats, 470

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, JULY 11, 1893.

We would call the especial attention of our readers to the annexed notice of a meeting held at Owego, in June, calling a Railroad Convention, to be held in that place on the 28th of the present month, July. The importance of the object of the Convention, to wit, the *New-York & Erie Railroad*, will unquestionably command the attention of the inhabitants of this city, as well as other sections of the State, interested in its furtherance.

**RAILROAD MEETING.**—At a meeting of the inhabitants of the county of Tioga, convened at the Court House in the village of Owego, on the 13th June, 1893, to choose delegates to represent this county, in a convention to be held at the village of Owego on the 29th July next, to take into consideration the projected Railroad from New-York to Lake Erie,—the Hon. John R. Drake was chosen President, Theodore North and Geo. Fisher, Vice Presidents, and E. S. Sweet and James Dunn, Secretaries.

Resolved, That a committee of four be appointed to report nominations of suitable persons for delegates. The committee retired and reported the following persons, who were unanimously appointed. From the Western Jury district, Theodore North, H. Luce, Wm. Maxwell, James Dunn, John Arnot, M. McReynolds, Hiram W. Jackson, E. Quinn, Charles Cook, J. G. McDowell, Jacob Westlake, C. Bennett, George Gardner.

From the Eastern Jury district, James Pumpelly, George Fisher, J. R. Drake, L. A. Burrows, Stephen Strong, Henry McCormick, S. B. Leonard, Saml. Baragar, G. H. Barstow, Wm. Ransom, Elijah Shoemaker, Thomas Pearlshall.—[Owego Gazette.]

[From the Buffalo Com. Advertiser.]

**NEW LINE OF CANAL PACKETS.**—We have been quite remiss in omitting to notice this new enterprise. For about two weeks past, a line has been running between this city and Rochester, performing the distance in about half the time heretofore consumed in making the passage by the ordinary packets. The great augmentation of speed is obtained by constructing the boats on a new plan, in which swiftness is especially consulted. They are built considerably narrower than the common boats very sharp at the bows, and exceedingly light; and it is found that the same power necessary to impel the common packets at the rate of four miles an hour, will enable those of the improved construction to move with double the velocity.

The originator of this improvement is Captain Seth C. Jones, of Rochester, who has been some time of the opinion that a boat might be so constructed as to be drawn by horse power at the rate of ten or twelve miles an hour. He accordingly tried the experiment, and found his expectations fully realized. It is demonstrated that when moving at the rate of seven or eight miles an hour, these boats ride upon the swell created, and thus receive a constant onward impetus, instead of laboring at the base of the wave, pushing it forward, instead of surmounting it.

The tow boats plying between this city and Rochester, are the "S. C. Jones" and "Ohio," both of which are elegantly and tastefully fitted up,—one leaving every afternoon, for the present, at 5 o'clock, P. M.

As there is a regulation prohibiting the running of boats on the canal at a rate exceeding four miles an hour, for the prevention of injury to its banks by excessive agitation of the water, application has been made to the Canal Board for permission to run these boats at the rate of ten miles an hour—as the swell created by them at that velocity is not greater than would be caused by common boats, at the ordinary rate. Should this permission be granted, as there is every reason to anticipate, two additional boats, of larger size, will be immediately added to the line. Those now running, average between seven and eight miles the hour. It having been stated that they made the passage through by day-light, it may be proper to mention that it is contemplated to do it, as soon as permission is obtained to that effect.

Capt. Jones is now on a visit to the cities of New York, Baltimore, and Philadelphia, for the purpose of procuring the information necessary to enable him to construct a *sheel* from Packet Boat, on the plan of those used in England; a model of which he intends bringing with him on his return, with a view of testing their practical adaptation to our own canal navigation. His enterprise is commendable and deserves success.

**QUICK CANAL PASSAGE.**—The Canal Boat Albany, Capt. Bromley, of the Transportation Line, made her last trip from Buffalo to this city, in four days and a half.—[Alb. Eve. Jour.]

[For the American Railroad Journal.]

## Foot Railroads.

It is proposed to show in this article, that railroads for short distances may be used to advantage by men to transport themselves and moderate loads by their own strength.

1. In showing this, I may first state the force of traction required on railroads. The force of traction is measured by a weight suspended to a cord passing over a pulley. The traction, or tractive power of a horse, is said to be 125 pounds, because a horse at his ordinary labor draws with a force sufficient to raise up 125 pounds by a cord over a pulley. The tractive power necessary to move waggons on common roads, and cars on railroads, has been very accurately ascertained. If a waggon with its load weighs 2400 pounds, then, if a weight of 800 pounds is suspended to a cord passing over a pulley, which cord draws the waggon, this weight would move the waggon forward on a good level turnpike road. But a car on a level railroad, weighing with its load 2400 pounds, would be moved forward by a weight of only ten pounds, suspended to a cord running over a pulley. If then a man could draw up a weight of ten pounds, he could, with the same rapidity that it ascends, move forward, on a level railroad, a car and its load weighing together 2400 pounds. If he could draw ten pounds up ten feet in a second, he could move the car and its load ten feet in a second; and if he could do this for an hour in succession, he could then move forward the car and its load 3600 feet in the hour. But if the railroad rises but 32 feet in a mile, the traction of 10 pounds will not move 2400 pounds up this ascent; but the traction of 10 pounds must be added, or the traction of 20 pounds will be needed; and if the ascent is 44 feet in a mile, another additional traction of 10 lbs. must be made, or there must be a traction of 30 pounds. The traction of 10 pounds, at 10 feet in a second, might be made to operate on a car 20 feet in a second; but the traction of ten pounds would not move a car weighing 2400 pounds 20 feet in a second, for it would propel only half the weight, or 1200; and if the traction of 10 pounds, at 10 feet in a second, were made to move a car 40 feet in a second, it would propel a car at this rate, weighing only 600 pounds. With the same power with which a weight of 2400 pounds is moved forward on a level railroad 3600 feet, a weight of

600 pounds might be propelled four times that distance, or 14,400 feet.

2. What now is the power ordinarily exerted by a laboring man? Different estimates are made of this power. By Dr. Farey, a recent writer on the steam engine, the power of man is assumed to be equal to the raising of 60 cubic feet of water, which is equal to 3750 lbs. avoirdupois, through the space or height of one foot in a minute. A stout laborer, says Dr. Farey, will continue to work at this rate during eight hours per day. The relative values of the labor of a man and a horse, as to physical strength exerted, are variously stated. Some estimate them as 1 to 5, some as 1 to 6, and some as 1 to 7. The efforts of men differ with the manner in which these efforts are employed. It has been estimated by Mr. Buchanan, that the same quantity of human labor employed in working a pump, turning a crank, ringing a bell, and rowing a boat, are as the numbers 100, 167, 227, 248. The strength of man could be applied in the most economical way on a railroad, and so as to act with even more efficiency than in rowing a boat. He might sit in a reclining posture like a man pulling an oar, with his feet pushing against the flat boards of a small wheel, and by his hands drawing upon the slats of a drum wheel, instead of drawing upon an oar, while the wheel on which his feet operate, and that on which his hands operate, act on the same working point. This machinery might occupy but about the space filled by two chairs, or very little more than is required by one man to sit at his ease.

Attempts have been made to construct carriages by which a man might propel himself on common roads; but a knowledge of the power of traction necessary on common roads, would show that this is wholly impracticable. If a man's weight is 175 pounds, it would require an additional tractive power of 14½ to move himself on a common road, while this additional power would of itself alone move forward on a level railroad 3480 pounds; but for a man to move himself forward on a level railroad would require an additional traction of only two thirds of a pound, if his weight is 175 pounds.

If a laboring man ordinarily exerts strength sufficient to raise 3750 pounds 10 feet high in a minute, then he could propel 3750 pounds 240 feet in a minute, or half a mile in 12 minutes; or he could propel 997 pounds one mile in six minutes, or ten miles in an hour, and do this for eight hours in a day.

3. The attention may now be directed to the various occasions persons have to go, or to carry goods for short distances. Among the new and striking circumstances that in the city arrest the visitor from the country, is the throng of carts, and carriages, and horses, crowding the streets, and stunning his ears. This fact shows that there is a vast amount of conveyance of persons and loads from one part of a city to another. While such an amount of transportation is demanded by the necessities and convenience of the people of a city, it is manifest that railroads along some principal streets, reducing the freight of goods and persons to one tenth, or one third of its present cost, would be an immense gain to the community. The result would be that much mechanic business needed in a city would be done at a distance, where there was more room, and where on many accounts it could be done to more advantage. By the railroad the mechanic would be as near his customers four miles off, as he is now one

third of a mile. From a centre of business a man might transport himself with great ease several miles for his food and lodging, since, as easily as he would walk up stairs, or up a hill, 22 feet, with two pounds weight in his hand, he could move forward a mile on a level railroad, transporting himself, whatever is his weight, and moving his car also weighing 480 lbs. Or, supposing that it is about as fatiguing to a man to walk at the rate of three miles an hour, as to work for that time with the strength of a laboring man, then, as easily as he could walk one mile to his lodgings or home, he could propel himself and car, weighing together 625 pounds, 4½ miles on a level railroad, and in the same time that he could walk a third of a mile. In the country an immense advantage would accrue from light and cheap railroads to centres of business, to get to stores, to physicians, to schools, to public lectures, and meetings, and to religious assemblies.

The influence of such means of communication on intellectual, moral, and religious improvement, I would set above all other advantages. The greatest mental and moral debasement is found in remote country neighborhoods, and in dark city lanes, and in their deep cellars.

4. The position of places of business is ordinarily such that they can be accommodated to a great extent by level railroads. Cities are commonly built on navigable waters; and the business in them is done along a water line, and here are ranged the workshops and stores. Railroads from the country will naturally terminate on this level, for they must be kept on low ground, and in the valleys of streams, which keep the lowest and most level courses. The railroads from Providence and Worcester terminate in Boston at what was once the neck, from whence very level rail paths might extend to the principal wharves, and indeed around the whole city. Rail tracks, extending from the termination of these railroads over the city, would greatly promote the success of the railroads, for, on a level track, a horse might draw several cars and loads, weighing together 12 tons. A car might receive the passengers directly from the steamboat, or travellers might enter one at their hotel, and without being delayed by the long process of getting seated at the head of the railroad, the cars, all loaded, might meet almost at the minute from different quarters, and pursue their course without hindrance.

Slight and cheap lines of railroad for the application of human power, intersecting the city and country, will accommodate especially the great body of the middling and poor classes, and may thus do as much good as the grand and heavy railroads, on which the ponderous cars of three and four tons weight are rolling; and they may add vastly to the business of these main channels of communication. If there are to be conveyed loads of 50, 100, 200, or 500 pounds, porters could convey them as easily on their light cars on rail tracks, as they could walk on a common road without any burden. To draw a load of 480 lbs. a man has to exert only the power that would raise two pounds over a pulley; and to move himself also on his load, he would have to exert only the additional tractive power of one third of a pound. The effect of cheap rail tracks would be as though a railroad terminated at each man's door.

By these facilities of communication, both the country and the town would be benefited. Labor is nearly double in the city what it is in the country; and this is a loss to

the laborer and the employer. It is a loss to the employer, because the labor he gets costs him so much; and it is a loss to the laborer, because his expenses are great and his accommodations poor. It is a loss also to the laborer in the country, because he cannot get the products of his labor to market without losing a great part of their value. The expense of transportation is a dead loss to the public; and by how much this expense is reduced, by so much is the whole public benefitted.

PUBLICOLA.

*Experiments on the Transverse Strength and other Properties of Malleable Iron, with Reference to its Uses for Railway Bars.* By PETER BARLOW, F. R. S., Cor. Mem. Inst. of France; of the Imp. and Roy. Acad. of Petersburg and Brussels, etc.

(Continued.)

Collecting the results of these seven experiments, (see opposite page,) and reducing them all to square inches, we find that the strain which was just sufficient to balance the elasticity of the iron, was in—

Bar, No.	(re-manufactured iron);	10 tons.
1.	ditto	11 "
2.	New Bolt	11 "
3.	ditto	10 "
4.	(re-manufactured)	9.5 "
5.	ditto, from old furnace bars,	8.25 "
6.	New bar, by Messrs. Gordon,	10 "
7.		

We may consider, therefore, that the elastic power of good iron is equal to about ten tons per inch, and that this force varies from ten to eight tons in indifferent and bad iron. It appears, also, (considering .000096 as representing in round numbers  $\frac{1}{10,416,667}$ th,) that a bar of iron is extended one ten-thousandth part of its length by every ton of direct strain per square inch of its section; and consequently, that its elasticity will be fully excited when stretched to the amount of one-thousandth part of its length.

*Remarks on the foregoing Experiments.*

These results have an important bearing on the question of railway bars. We shall see, in the following section, how they become applicable to the investigation of the transverse strain; but, at present, I shall only speak of them as they apply to the fixing of the rail to the chair. Amongst the numerous models which the Directors did Messrs. Rastrick, Wood, and myself, the honor to submit to our inspection, for the purpose of awarding their prize, there were several in which it was intended to fix the rail permanently to the chair—a very desirable object, if it could have been safely adopted; and it was the want of data to enable us to decide on this point, which first led me to propose this course of experiments. The question is now satisfactorily answered. We have seen that, with about ten tons per inch, a bar of iron is stretched  $\frac{1}{10,416,667}$ th part of its length, and its elasticity wholly excited or surpassed. Again, admitting 76° to be the extreme range of the thermometer in this country between summer and winter, it appears, from the very accurate experiments of Professor Daniell,\* that a bar of malleable iron will contract with this change  $\frac{1}{10,416,667}$ th part of its length. And hence it follows, that if the rails were permanently fixed to the chair in the summer, the contraction in the winter would bring a strain of five tons per inch upon the bar, and a strain of twenty-five tons upon the chair, (the bar being supposed of five-inch section,) thereby deducting from the iron more than, or

full half, its strength, and submitting the chair to a strain very likely to destroy it. Every proposition, therefore, for permanently attaching the rail to the chair is wholly inadmissible.

These remarks may also be carried still farther. If it be dangerous to attach the rail *directly* to the chair, it must be bad in practice to affix it *indirectly* by wedges, cotters, or otherwise, beyond what is absolutely essential to give it steadiness under the passing load; for it is evident, that if by these means we could prevent any motion taking place, we should fall into the same evil as by the permanent attachment; and if, as most probably will happen, we fail of entirely accomplishing this, still all the friction which is produced must be overcome by the contracting force of the iron, and be so much strength deducted from its natural resisting power.

The problem, therefore, which engineers have to solve, is, "To find a mode of fixing the rail to the chair, which shall give sufficient steadiness to the former; but which, at the same time, shall produce the least possible resistance to the natural expansion and contraction of the bar."

The quantity of motion which thus takes place is certainly but small, viz. about  $\frac{1}{4}$ th of an inch between summer and winter, with a fifteen-foot bar; but the force of contraction is great, amounting to five tons per sectional inch for the annual extremes, and frequently to not less than two and a half tons between the noon and night of our summer season, while the whole power of iron within the limits of its elasticity does not exceed nine or ten tons.

This is an important consideration, and for want of attention to it, or rather, in consequence of its amount not having been ascertained, a practice of wedging or fixing the rails has prevailed, which must necessarily have been the cause of great destruction to the bars.

I would also suggest here, as a matter deserving the attention of practical men, that as the bar must necessarily contract, it will draw from that side, which is least firmly fixed, and hence all the shortening will most probably be exhibited at one end, however slight the hold on either may be; and when it happens that the adjacent ends of two bars both yield, the space between the two is rendered double that which is necessary. To avoid this evil, one of the two middle chairs in each bar might be permanently attached to the rail, in which case the contraction must necessarily be made from each end, and the space occasioned by the shortening of the bars would then be uniform throughout, and much unnecessary and injurious concussion thus saved both to the rail and to the carriage.

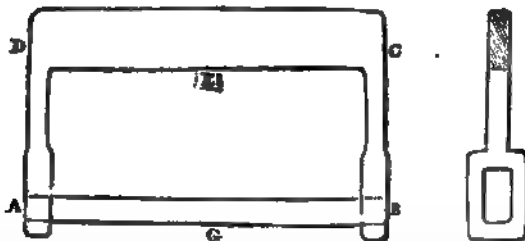

Experiments to determine the comparative Resistance of Malleable Iron to Extension and the Depression, and the position of the neutral axis in bars submitted to a transverse strain.

Let A B (see figure 1, on the following page) represent an iron or any other bar supported at A and B, and loaded in the middle by a weight W, which deflects it; extending the fibres between n and c d, and compressing those between n and c' d. Now, supposing the system in equilibrio,  $\frac{1}{2}$  W acting at the extremity of the  $\frac{1}{2}$  length, or  $\frac{1}{2}$  l W, is equivalent to the sum of all the resistances to extension in n c d, and to all those of compression in n c' d, each fibre acting on a lever equal to its distance from the neutral axis n. Consequently, as the quantity of extension of any fibre is as its distance from the neutral axis, and the

Fig. 1.

Fig. 2.

lever by which it acts, being also as that distance, the actual resistance of a fibre at the distance,  $x$ , is as  $\frac{x^2 t}{d}$ ,  $t$  being the tension of the lower fibre, and  $d'$  its depth below the neutral axis; and the sum of all these resistances will be  $\int \frac{x^2 t}{d} dx = \frac{1}{3} d' t$ , (when  $x=d'$ ) or for the whole depth. In the same way,  $c$  being taken to denote the compression of the upper fibre, corresponding to the tension  $t$ , the sum of all the compressions will be,

$$\frac{1}{3} d'' c, \quad d'' \text{ denoting the depth of compression;}$$

hence the whole sum is,

$$\frac{1}{3} d'' c + \frac{1}{3} d' t = \frac{1}{4} W l;$$

but  $d'' c = d' t$ , the quantity of resistance being equal to that of extension; this, therefore, becomes

$$\frac{1}{3} d' d' t + \frac{1}{3} d' t = \frac{1}{4} l W, \text{ or}$$

$$\frac{1}{3} (d' + d') d' t = \frac{1}{4} l W, \text{ or}$$

$$\frac{1}{3} d' d' t = \frac{1}{4} l W;$$

$d$  being the whole depth, and  $d'$  the depth of tension; whence,

$$d' = \frac{3}{4} \frac{l W}{d} = \text{depth of tension, and}$$

$$d - d' = \text{the depth of compression,}$$

consequently,  $\frac{d'}{d-d'}$  the ratio, in which the neutral axis divides the sectional area in rectangular bars.

#### Comparison of the Formula with Experimental Results.

In order to submit this formula to practical results, a strong iron frame was forged, of the form shown above, (see figure 2); D C is thirty-six inches long, six inches

arms two  
proportional  
be proper to

taking a  $t$   
fibre to the

dimensions to those represented. The other view of the arms is represented in the side figure, with an opening six inches by three, in which the bars for experiment were placed, as represented by A G B; the space between is thirty-three inches. The shackles were applied at E and G, and connected by strong iron cables to the press; the strain was then brought on and the results recorded.

In order to measure with every requisite accuracy, the deflections which the bar sustained, as different weights were applied, an instrument of the form shown in the annexed figure was neatly and accurately

made in iron, having two feet, A D, B C; the centre was tapped to receive the brass screw, H S, of twenty threads to the inch, and the head was divided into five equal parts, and by again subdividing these divisions into ten, a deflection of  $\frac{1}{1000}$  of an inch might be measured with great ease.

The method of applying it was to rest its feet on the bar, and then to retain it in its place by cramps and screws. The micrometer screw was then run down till it was in contact with the bar, and the divisions read and registered, either before any strain was on, or when the first slightest strain could be estimated, as stated in the following table.

Experiments made to ascertain the Deflections due to different Transverse Strains, and the Weight which first produces a Strain equal to the Elastic Power, and thence the position of the Neutral Axis.

Elasticity clearly injured by the former experiment.

The first six experiments were made on different parts of the bars, Nos. 5, 6, and 7, without cutting them, by introducing them into the iron frame above described (having thirty-three inches clear bearing,) and straining them till the successive deflections showed a tendency to increase in amount, which was taken as a sign of the elasticity being injured; and the amount of this strain having been previously ascertained by the former experiments, they furnish the best possible data to apply to the formula for determining the position of the neutral axis.

It appears from these experiments, that both parts of the Bar No. 5, (whose direct elasticity was 9.5 tons,) had their restoring power just preserved with a transverse strain of two and a half tons on a bearing length of thirty-three inches. Hence in the formula:

$$d' = \frac{3lw}{4d}$$

we have  $l=33$ ,  $w=2\frac{1}{2}$ ,  $d=2$ ,  $d'=9.5$ , and  $d'=1.63$  inches, depth of tension.

Consequently  $d'=38$  inches, depth of compression, and the ratio of the area of compression to tension 1:4.8

In the first part of Bar No. 6,  $w$  is not quite 2 tons, and  $l=8.5$  tons; and hence the ratio 1:2.7

In the second part of the same bar, ditto 1:2.7

In the first, second, and third parts of Bar No. 7,  $w=2\frac{1}{2}$  tons, and  $l=10$  tons 1:3.4

As far as these experiments are authority, therefore, the neutral axis divides the sectional area of a rectangular bar in about the ratio of one to three and a half.

In the following experiments, the iron was all supplied by Messrs. Gordon, and was of the same quality as the Bar No. 7,—its elasticity may therefore be taken as ten tons, but it was not determined by testing, as in the preceding experiments.

Deductions from the three last Experiments, confirmed by direct Observation of the place of the Neutral Axis.

These experiments, like the former, imply, according to the formula, that the neutral axis lies at about one-fourth or one-fifth of the depth of the bar from its upper surface; but a method was adopted in these to discover, if possible, its position mechanically. With this view, a keyway, or groove, was cut in the side of the bar one inch broad, and one-tenth of an inch deep,—thus reducing the breadth to 1.9 inches. To this keyway, or groove, was fitted a steel key, which might be moved easily; and when the strain was on, the key was introduced, which it was expected would be stopped at the point where the compression commenced, and this was accordingly found to be the case in two out of the three bars, but not in the third, the fitting not being sufficiently accurate. The other two, however, showed obviously a contraction of the groove, as about half an inch from the top, agreeing with the preceding computations. To make the results more certain, three other bars, exactly like the former, had deeper grooves cut, and the key more exactly fitted, and with these the results were as definite as could be desired. The key, as above-stated, moved smoothly and easily before the experiment; but when two tons strain were on, and the key applied, it was stopped, and stuck at a definite point. The strain being then relieved, the key fell out by its own weight; the strain was again put on, the key sticking as before; the strain being relieved, the key again fell, and so on, as often as repeated. Precisely the same happened with all the three bars. One of them was then reversed, so that the part which had been compressed was now extended, and exactly the same result followed: showing, most satisfactorily, that our former computed situation of the neutral axis was very approximate. The measurements obtained in these experiments being tension 1.6, compression .4 giving exactly the ratio of 1 to 4 in rectangular bars. These results seem the most positive of any hitherto obtained; still, there can be little doubt this ratio varies in iron of different qualities; but looking to the preceding experiments, it is probably always between 1 to 3, and 1 to 5.

On the Stiffness of Rectangular Iron Bars, and their Deflections under different Weights.

Although it is necessary to know the actual resisting power of bars in their ultimate state of strain, in order to determine the relative strengths of differently-shaped bars, yet the question of most practical importance is the stiffness they exhibit when loaded with smaller weights; for we ought never to strain a bar so nearly to its full power of bearing, as to make this the immediate subject of inquiry.

The experiments recorded in the last section are applicable to this purpose, but as these are all of the same depth, it was thought more satisfactory to make a few other experiments on bars of different breadths and depths. They were performed precisely like the last, and therefore require no particular description.

To reduce the law of deflection from these results, we may have recourse to two well known and well established formulae: viz.

$$\frac{l^3 w}{4 a d^3} = S \text{ and } \frac{l^3 w}{a d^3} = E.$$

which are both constant quantities for the same material,  $w$  being the greatest weight

Experiments on the Deflection of Malleable Iron Bars, under different Strains.

the bar will bear without injuring the elasticity; consequently, when  $l$  is also the same in both,  $d'$  will be also constant,  $a$  being the breadth,  $d$  the depth, and  $\delta$  the deflection. That is, all rectangular bars having the same bearing, length, and loaded in their centre to the full extent of their elastic power, will be so deflected, that their deflection ( $\delta$ ) being multiplied by their depth ( $d$ ) the product will be a constant quantity, whatever may be their breadths or other dimensions, provided their lengths are the same.

Let us see how nearly our several results agree with this condition.

In the several bars, Nos. 8, 9, 10, 11, 12, 13, multiplying the mean deflection for each half ton, by the number of half tons which excited its whole elasticity, and this again by the depth of the bar, we find

	Depth.	
No. 8, ultimate deflection	$.109 \times 2 =$	2160
No. 9	$.094 \times 2 =$	1860
No. 10	$.120 \times 2 =$	2400
No. 11	$.0876 \times 3 =$	2628

No. 13	$.1038 \times 2\frac{1}{2} =$	2595

6) 14417

Mean -2403

There is rather a large discrepancy in bar No. 9; the others are as approximate to the mean as can be expected in such cases.

If we make the same trial on the three parts of bar No. 7, we have,

1st part .116	×	2	=	.2320
2d part .105	×	2	=	.2100
3d part .115	×	2	=	.2300

3) 6720

Mean	-	-	-	.2240
Former Mean	-	-	-	.2408

2) 4647

General Mean - - - .2323

We may therefore say, that any malleable iron bar, of 33 inches bearing, being strained to its full elasticity, will be so deflected, that its depth, multiplied by the deflection, due to 30 inches, will produce the decimal .23; consequently  $\frac{.23}{d}$  = the deflec-

tion,  $d$  being the whole depth in inches.

In this form, however, it applies only to rectangular bars. To make it general, we must estimate it from the neutral axis, which in rectangular bars, being  $\frac{1}{4}$ th of the depth below the upper surface, the above constant, when thus referred, becomes  $.2323 \times \frac{3}{4} = .1853$ . But, on the other hand, our instrument for measuring the deflection was but 30 inches long; it has therefore to be increased again in the ratio  $30^2 : 33^2$ , or as  $10^2 : 11^2$  on this account; so that, ultimately, the formula is  $d' d = .22 d'$  denoting now the depth of the bar below the neutral axis, and in this form it is general for parallel rails of any section whatever.

A curious circumstance was observed in these experiments, which, although it has no immediate bearing on the subject in question, it may be well to notice, and which is, I apprehend, characteristic of good malleable iron, viz. that the resistance to compression, although so much greater than the resistance to extension, is the first of the two which loses its restoring power; for if we so far increased the strain as to overcome the elastic power, the point of compression descended to nearly the middle of the depth, proving that the tensile force, although so much less, is the most tenacious; whereas I suspect, that in cast iron it is the reverse, that is, it is here the tensile power which first yields, and the consequence is a sudden fracture, and momentary destruction of the bar.

**WASHINGTON AND BALTIMORE RAILROAD.**—Earlier than we anticipated, the Railroad between this city and Baltimore is about to be brought into use, to the great joy, no doubt, of all who have need to go to and from Washington in a direction north of it. On Wednesday, the President and directors, with the principal officers of the Washington and Baltimore Railroad Company, accompanied by several invited citizens of Baltimore, made a trip of inspection on the new road, from Baltimore to Bladensburg, at which place the company was met by the Mayor of this city and some other gentlemen who take much interest in the success of that great undertaking. We are gratified to learn from one of our citizens who travelled the whole way from Baltimore in the car, (which was drawn by a locomotive engine,) that the great satisfaction was expressed at the manner in which the road has been constructed. The rails are of an improved construction, and greatly superior to any heretofore in use. The engine is of great power, and of the most approved construction, and the cars destined for this road superior to any heretofore in use, containing comfortably, within the body of each, sixty passengers.

The company would have been able to have opened the road through to their terminus in this city, but for the unaccountable delay in the arrival of a cargo of rail-iron, which did not sail from England until the 16th May, instead of the middle of April, as ordered.

We are pleased to learn that an arrangement has been made by the enterprising stage company of G. Beltzhoover & Co. with the Railroad Com-

pany, to open the road on Wednesday next; the passengers, until the final completion of the road to the canal basin in this city, to be conveyed from Bladensburg to the city in stage coaches. So that a person may hereafter go and return between Washington and Baltimore in less time than, when travelling at the fastest rate, it used to take to accomplish the single distance between the two cities. —[Nat. Int.]

The Baltimore Gazette furnishes us with the following remarks and report, which will afford pleasure to all our readers who take an interest in the progress and permanence of that Herculean work, the Baltimore and Ohio Railroad.

In reference to the Baltimore and Ohio Railroad, we have frequently taken occasion to remark upon the substantial and permanent manner in which the buildings, and all the other operations of that company have been constructed. We have uniformly approved of this policy, which, we are still satisfied, will in the end be found most economical and beneficial to the stockholders. Having understood that a thorough inspection had recently been made, of all the masonry on the road, we called at the office of the company and requested to see the report on this important part of the work. This permission was readily granted to us, as well as the liberty to publish the report if we desired to do so. Considering the information it discloses to be of deep interest to a large number of our readers, we now submit the same as follows:\*

Engineer's Office,  
Baltimore and Ohio Railroad, June 20, 1835. }  
To PHILIP E. THOMAS, Pres't. &c.

I have now the honor to enclose a report dated the 18th inst., made to me by Robert Wilson, Assistant Superintendent of Masonry, relative to the condition of the masonry and bridges upon the Baltimore and Ohio Railroad between this city, Frederick, and Harper's Ferry, comprising a distance of about 85 miles.

This examination has been made in pursuance of the letter of instructions to me, dated the 24th of October last. The delay of this inspection of the masonry from the autumn, until the spring season, was the result of imperious calls upon my time in the railroad service, and as these circumstances are all familiar to thee, I need now only remark, that finding it wholly impossible to give my personal attention to the examination, I confided, with my verbal permission, the service to Robert Wilson, Assistant Sup't of Masonry in the service of the Company, in whom I have full confidence. His report now presented, and already referred to, is highly satisfactory, as showing the good condition and great permanency of the mason-work upon the entire line of railroad already completed to Frederick, and to Harper's Ferry, the repairs required and recommended being only to the amount of one hundred and eighty dollars.

As these repairs have been deemed necessary, I recommend that they be made without delay, under the inspection of Robert Wilson.

In confirmation of the opinions which this officer has expressed, I may add, that I have heretofore frequently inspected the mason work upon the whole line, and likewise upon the Washington Railroad; and am of opinion that it has been most faithfully executed, and of materials of the most

\* It should be recollected that a considerable portion of this masonry has been built more than 4 years.

substantial character; and I do not hesitate to add, that I know of no public work of internal improvement in this country involving so much masonry of a character so substantial.

J. KNOWN,  
Chief Engineer B. & O. Railroad.

BALTIMORE, June 18th, 1835.

Jonathan Knight, Esq.

Chief Engineer B. & O. R. R.

Sir:—Your letter of the 2nd May, 1835, has been received, requiring me to make a minute examination of the masonry on the line of the Baltimore and Ohio road, from its commencement to its termination at Harper's Ferry, together with the actual situation of the wooden viaduct over the Monocacy, and report thereon respectively.

Pursuant to your instructions, those examinations have been carefully made, and it is with much satisfaction I am enabled to state that the masonry on the entire line,

repaired,	"	3

\$180 making together \$180 as the aggregate costs of all the repairs deemed necessary to place the masonry in a sound condition, which allowance, it is confidently believed, is amply sufficient to effect the purpose, provided the work be executed under the direction of the supervisors on the road. It is proper to remark that the greater part of these repairs might be at present dispensed with, as, for instance, the pointing of the several viaducts, together with the paving of viaduct No. 2, on the 11th mile. I would, however, recommend that all the repairs mentioned be now made.

59th mile—the Monocacy viaduct on this mile appears in good order, except that a slight repair to the weatherboarding on the north side is necessary.

Respectfully submitted,

ROBERT WILSON,

Asst. Sup't. of Masonry.

**BOSTON AND WORCESTER RAILROAD.**—On Friday last, the locomotive engine and passenger car, for the first time passed over the whole of this road from this city to Worcester. The Directors, and a number of other gentlemen, left this city at half-past 9 o'clock, with one of the engines, and after viewing the whole extent of the road—stopping three times by the way—once as much as fifteen minutes, they arrived at the termination of the road on Main street, in Worcester, at a quarter past 5. After a stay there of near an hour they set out on their return, and would have made their passage to Boston, exclusive of two short stops at Westborough and Needham, in two hours, had not their process been interrupted in Newton, by an accident which had happened to the engine of the regular afternoon train, and detained it on the road. The forward axle of the engine was broken, and it was necessary to remove the engine from the road, and to bring the whole load, consisting of about twelve cars, with a very large number of passengers, into town with one engine. In consequence of this accident, the train did not reach town until after ten o'clock.

On Saturday, the 4th instant, the four engines on this road, in conformity with the notice previously given, made each four trips between Boston and Worcester; two engines with eleven cars leaving each end of the road at the same time, at intervals of four hours, and conveying, during the day, more than fifteen hundred passengers. Each engine (with the exception of one which omitted one trip) and car travelled 176 miles in the course of the day, generally with full loads, and no accident or detention occurred during the day.

An instance of despatch, in the workshop of the corporation, deserves to be mentioned to the credit of the mechanics employed. In consequence of the accident above mentioned, to one of the engines on Friday evening, the engine was not hauled into the depot until 12 o'clock at night. The axle was then repaired, and the engine took her place on the road at 6 o'clock in the morning.

The Directors and Stockholders of the corporation and other gentlemen to the number in all of nearly three hundred, will proceed to Worcester to-day, in celebration of the opening of the railroad, having been invited to partake of a collation, by the citizens of that place.—[Boston D. Advertiser.]

Extract of a letter received by a commercial house in this city from their correspondent at Apalachicola, dated 25th June.—“Books of subscription for the capital stock of the Lake Winico and St. Joseph's Canal Company, were opened a few days since, the whole of which was immediately taken. The object of this Company is to connect the waters of the river Apalachicola with the Bay of St. Joseph's by a Canal or Railroad. The latter has been decided on for the present. The Bay of St. Joseph's is decidedly the best harbor in the Gulf of Mexico, having twenty-two feet on the bar at low tide and of easy access. It is fifteen miles in length, and from four to six in width, and will no doubt prove healthy, as there is no fresh water emptying into it—surrounded by a beautiful sand beach, and free from those marshes and stagnant water, the fruitful sources of disease in our Southern bays. The consequence, which may grow out of the successful completion of this work, it is impossible to foretell. By reference to the chart of the coast, made under the direction of General Bernard, you will find that these short cuts, less than twenty miles in all, will open an inland steamboat navigation from the Mississippi to St. Joseph's. The Company have purchased five sections of land in St. Joseph's, and are laying off a town on a beautiful elevated plain, about half way up the Bay. The loss will be brought into the market early in the Fall. Every exertion will be used to have the road, wharves, depots, &c. finished in time for the transportation of the crop. The distance from the head of the steamboat navigation on Lake Winico, to the site selected for the town in St. Joseph's, is a fraction less than six miles, and passes over a level pine wood country, affording the choicest timber for the road, right on the spot. The Company have acted wisely in the distribution of the stock. Three eighths have been transferred to the merchants of Columbus, Georgia; one fourth to gentlemen in Tallahassee; and the remainder is retained by the present citizens of Apalachicola. The latter are making preparations to remove en masse to St. Joseph's, and already a number of store houses, and one extensive tavern have been contracted for.—[Journal Commerce.]

The resolutions of the Canal Board, respecting the enlargement of the Erie Canal and its locks, will be found in our columns to-day. The doubling of the locks is, it will be seen, to be set about immediately. The enlargement of the canal cannot be undertaken until enough is in hand, from the revenues of the canal, to extinguish the existing debt. Meantime, however, surveys, &c., are to be made.

[From the Albany Argus.]

**ENLARGEMENT OF THE ERIE CANAL.**—The great increase of business on the Erie Canal, and the rapid settlement of the country seeking a market through that channel, having demonstrated the importance of enlarging and improving the canal, an act authorizing the work was passed at the last session of the Legislature. The Canal Commissioners were directed to commence the enlargement of the canal and the construction of a double set of lift locks, “as soon as the Canal Board may be of opinion that the public interest requires such improvement;” and “the dimensions to which the canal and locks shall be enlarged shall be determined by the ‘Canal Board.’” In pursuance of the authority delegated for that purpose, the Canal Board met at the Comptroller's office in this city, on the 30th ult., and on Friday last adopted the following resolutions:

At a meeting of the Canal Board, at the Comptroller's office, Canal Room, 3d July, 1835,—present—

STEPHEN VAN RENSSLAER, Canal Commissioner, President,  
SAMUEL YOUNG, Canal Commissioner,  
WM. C. BOUCK, do  
JONAS EARLE, Jr., do  
JOHN BOWMAN, do  
JOHN TRACY, Lieutenant Governor,  
A. C. FLAGG, Comptroller,  
JOHN A. DIX, Secretary of State,  
GREENE C. BRONSON, Attorney General.  
WM. CAMPBELL, Surveyor General,  
ABRAHAM KEYSER, Treasurer.

The Board having taken into consideration the act entitled “an act in relation to the Erie Canal,” passed May 11, 1835, thereupon,

1. Resolved, That the public interest requires the enlargement and improvement of the Erie Canal, and the construction of a double set of lift-locks therein.

2. Resolved, That the doubling of the locks, and the works connected therewith, ought to be commenced without delay and prosecuted with all reasonable diligence, beginning with that portion of the canal between the village of Syracuse and the city of Albany.

3. Resolved, pursuant to the 10th section of said act, That the enlargement of the canal should be commenced immediately after a sufficient sum shall have been collected and invested from the canal revenues, to discharge the Erie and Champlain canal debt.

4. Resolved, That the Canal Commissioners proceed without delay to make surveys for all the improvements contemplated by the said act, and that they make the necessary appropriation of all lands, waters and streams for the purposes afore said.

5. Resolved, That the canal be enlarged so as to give six feet depth of water, and in general, sixty feet width of water on the surface, with a slope of two feet to one in the banks.

6. Resolved, That the locks be enlarged so as to be one hundred and five feet long between the quoin posts, and fifteen wide in the clear, and in other respects be adapted to the enlarged canal.

7. Resolved, That the aqueducts be constructed so as to give at least forty feet water-way, except that the Rochester aqueduct may, in the discretion of the Canal Commissioners, be constructed with a water-way not less than thirty-six feet wide.

8. Resolved, That in other respects than those provided for by the foregoing resolutions, the Canal Commissioners make such improvements in the canal, and the works connected with the same, as they shall deem expedient.

9. Resolved, That the Canal Commissioners be requested to cause such examinations and estimates to be made as the time will permit, for the purpose of ascertaining the practicability and probable expense of an enlargement of the canal so as to give the several sizes of six and seven feet depth of wa-

ter—the width at surface to be in general ten times the depth of water.

10. Resolved, That the Board, when it adjourns, will adjourn to meet at this place on Tuesday, the 20th day of October next, to hear the report of the engineers, and consider further of this subject.

An extract from the minutes.

G. W. NEWELL, Clerk.

[From the Utica Observer.]

UTICA, May 22d, 1835.

A. G. Dauby, Esq.: Dear Sir,—I take the liberty of sending you the following correction of the statement in Williams' Register for 1835, of the length and cost of the New-York State Canals.

SUMMARY OF CANALS COMPLETED.

Name.	Length.	Cost p. mile.	Total cost.
Erie Canal.....	364	372	19,255 49 7,143,789 86
Feeder.....	8		
Champlain Canal.....	64		
Glen's Falls Feeder.....	12		
River navigation ab.		70	15,530 95 1,257,604 36
Troy dam.....	3		
Oswego Canal.....	38	14,879 98	565,687 35

Feeder.....do.....	16		
Crooked Lake.....do.....	8	19,597 11	156,776 90

Total miles, 559 Cost, \$9,692,108 68 or an average of \$17,367 57 per mile.

The Chenango Canal is now constructing, to be completed in 1836, is 97 miles long, 1021 feet of lockage by 100 locks, and is estimated by the Canal Commissioners to cost 1,960,456 28, or \$20,210 87 per mile, exclusive of land damages.—(Assembly Document of 1835, No. 296.) A. B.

**STEAMBOAT CANAL ACROSS THE ISTHMUS OF DARIEN.**—The Journal of Commerce, says:—By the annexed extracts from the Constitutional del Cauca, (New Granada,) which we find in a Jamaican paper of June 15th, loaned us by a friend, it will be seen that the object of Mr. Clay's resolution adopted by the Senate at the last session of Congress, in regard to a navigable communication across the Isthmus of Panama, is likely to be accomplished by private enterprise.

[Translated.]

“We are gratified in being able to make it known, that the Baron de Thierry has directed Post-Captain Labarriere, (of the new Grenada Navy,) to proceed to the Capital of this Republic, with proposals for cutting a Canal, which will unite by their own waters, Rio Chagres with Rio Grande, the latter having its outlet in the Pacific, and to make make both navigable by steamboats and small vessels, not drawing more than ten feet of water.

“It is admitted that the communication between the Atlantic and Pacific, by means of a carriage road, would be very advantageous; but how much greater facilities Steam Navigation would afford, by the contemplated Canal!

“Mercantile enterprise could be carried on to any extent. The transport of merchandize would be safe and expeditious, as steamers would be in continual readiness, and not subject to that constant expense required to keep a railroad in order, nor to many other inconveniences, as the Baron has pointed out in a note, which he has addressed through the Deputies of Panama, to the National Congress.

“It appears from several antecedent details, with the perusal of which we have been favored, that the Baron undertakes this gigantic concern, not for any individual benefit, but his principal object is to shorten the route between England and New Zealand, to which he is now proceeding to establish a Government on the European plan, and to encourage emigration to that fertile and extensive country, in which all the productions of the earth may be raised with the greatest ease and abundance, particularly the silky flax, (phormium tenax,) being an article of such great value in the commercial world.

“The Baron has ample funds of his own, and credit with several European Bankers; and the Canal being the most important of his present undertakings, we have no doubt of his success.”

In laying before our readers this interesting com-

We have been favored by Mr. Clute, of Schenectady, with the annexed specification and engraving of his improved furnace.

References—*a a*, apertures for iron; *b b*, grates; *c c*, receivers; *d d*, branches of main blow-pipe; *e e*, main blow-pipe; *g g*, cylinder boiler; *h h*, apertures for coal.

*Specification of a Patent granted to PETER I. CLUTE, of Schenectady, New-York, for an Improvement in the Process of generating Heat, for forging Malleable Iron, and generating Steam to propel Machinery.*

Be it known, that I, Peter I. Clute, of the city of Schenectady, in the county of Schenectady, and state of New-York, have invented a new and useful improvement in the art or process of generating heat for forging malleable iron, and of generating steam to propel machinery for the purpose of grinding and polishing iron when manufactured, and for the other purposes for which steam power is generally employed.

The following is a description of the construction and operation of the furnaces and apparatus to be used in my invention.

Where other than a cylinder boiler, or where more than one boiler, is designed to be used, a given number of furnaces of the description hereinafter set forth, are to be erected under the same, arranged in the most convenient form, to receive as many points of the boiler or boilers, as, according to the principles hereinafter laid down, may be deemed most expedient; as, for example, in a circular form.

The cylinder boiler, however, I deem best adapted to the contemplated purposes of my invention.

Where the cylinder boiler is used, the number and size of the furnaces will vary according to the size of the boiler, and the quantity of steam required to be raised. The furnaces are to be built in a straight line, of uniform width and height, equidistant and continuous, the boiler to be laid horizontally or lengthways on the top of the furnaces. There is an aperture at either end of each furnace, through which the coal is shovelled on the grate, and the fires fed as occasion requires. Under each grate there is a box, which I shall designate by the

name of receiver, because it receives the blasts from the blow-pipe and the ashes falling through the grate. The receiver may be taken out and cleaned when necessary. Each receiver has at one of its sides an aperture for receiving a branch of the blow-pipe. There are, of course, as many branches to the main blow-pipe as there are furnaces, and the blow-pipe is connected with the bellows, which is worked by the steam the heat of the furnaces generates. The branch blow-pipe enters the receiver about at its centre, at a point equidistant from the grate and the bottom of the receiver, thus causing the wind in the receiver to circulate equally. There is an aperture near the top of the furnace, in front, through which to protrude the iron to be heated.

This aperture may be closed by a valve when not used.

Let the cylinder boiler be 20 feet long and 2½ feet in diameter; then there ought to be about seven furnaces, and the proportions of the different parts of the furnaces, &c., ought to be, as nearly as may be, as follows: Distance between the grate and the boiler, twelve inches; length of grate, eighteen inches; width of grate, eight inches; width of the furnace to correspond with the size of the grate; the aperture at either end, to admit the coal, to be 8 inches in width, and 6 inches in height; the receiver, 8 inches in width, and 6 inches in height; aperture for receiving the blow-pipe, 1½ inch in diameter; aperture through which to heat the iron intended to be worked, 6 inches in width, and three inches in height; distance between each grate, three eighths of an inch; diameter of blow-pipe, 4 inches, and diminished to one inch and a half at the entrance into the receiver.

The strength of the blast required is equal to that of a blacksmith's fire. The degree of heat may be regulated by valves placed in the blow-pipe.

I do not claim to have discovered or invented any thing new in the construction of the furnaces *abstractly* considered, or in any of the apparatus connected with the steam engine, nor can my invention in strictness be considered as an improvement of a machine or instrument previously patented; nor can it be considered an application of an old instrument or machine to a new purpose. What I claim as new, and my own invention, may be reduced to the following particulars:

1st, The using a number of furnaces to raise steam; 2d, the process of heating the boiler *uniformly* at many points, thus differing from the universal practice which now obtains, of heating the boiler at one particular point; 3d, the employing the same steam raised by the furnaces in driving the bellows connected with these furnaces; 4th, the application of the blow-pipe to ignite anthracite coal for raising steam; 5th, the using the same fire for the double purpose of raising steam and heating and working malleable iron.

I consider these two last particulars the most important, and as in especial manner distinguishing my invention from every other. This apparatus possesses a highly important advantage, in that it may be used for *manifold* purposes—for the manufacture of malleable iron into the different articles usually made by blacksmiths, and edge tools, nails, &c., and the steam power may be applied to grinding and polishing the iron, when manufactured, to propelling boats, driving a trip-hammer and mills of every description, and the other purposes for which steam power is generally employed.

PETER I. CLUTE.

#### AGRICULTURE, &c.

[From the American Gardener's Magazine.]

*On Budding Trees and Shrubs.* By the CONDUCTORS. To which is added, the different modes of Budding; and of Herbaceous, or Summer Grafting, extracted from Loudon's Gardener's Magazine.

The propagation and multiplication of the different species and varieties of trees, shrubs, and plants, especially kinds of delicate growth, is, we believe, quite imperfectly understood, in this country. The common methods of grafting and budding have long been in practice, as almost the only means of increasing plants, unless it were those which propagate easily from cuttings, suckers, or division of the root. We have lately observed in some of the nurseries which we have visited, several methods in practice which were quite new to us, and which we should think, from the success attending the practice, would, if become extensively known, be the means of greatly facilitating the multiplication of many delicate kinds, which it has been found exceedingly difficult to increase to any extent.

With trees, the common method of grafting is generally adopted, and in budding, the old system is almost universally pursued. Very few attempts have been made to render practicable and successful many of the new and more recent methods, laid down in most horticultural books, more particularly those in use by the French, who far excel even the English horticulturists in the multiplication of plants; this is owing to their knowledge in vegetable physiology, and to the various experiments which they are continually making for the discovery of some new method.

The following article we have extracted from Loudon's Magazine, with the hope that it will suggest some new ideas, as well as present some new methods, upon budding and herbaceous grafting, which will not fail to be of great benefit to individuals, as well as to the public in general. It was translated from a Belgium work, by Mr.

Loudon, the indefatigable editor of the Gard. Mag., with some additions and alterations; but as we are sure it will be one of the most interesting articles in our present number, we present it entire.

"The following article we have translated, with some additions and variations, from *l'Horticulteur Belge*; and we present it to our readers as more complete than any article which has hitherto appeared on budding and herbaceous grafting in the English language. We have given the French names of the different kinds, both of budding and grafting; not only because we think the doing so will be useful to gardeners who visit the Continent, or read French books on gardening, but because many of the terms are not translated literally. For example, the French apply the word *greffe* (graft) as a generic term, including both grafting and budding; whereas the English, and also the Germans, use distinct words for these two kinds of operations. The Germans use the word *veredlung*, ennobling or improving, as including both grafting, *pfropfen*, and budding, *oculieren*. In English we have no gardening word to express the two operations, although the word incision might be used for this purpose.

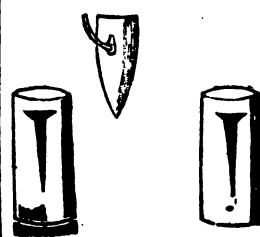

#### I. BUDDING. *Greffes par Gemmes.*

1. *Escutcheon Budding, without a Bud or Eye; Greffe en Ecusson sans Yeux.*—The object of this mode of budding is simply to cover a wound or blemish in one tree by the live bark of another. Take from a tree of the same sort, or at least of the same genus, as the wounded tree, a piece of bark rather larger than the wound, and form it into a regular shape; then cut the bark round the wound into the exact form and dimensions of the piece to be inserted, so that the latter may be let into the former with the greatest exactness. The inner bark of the graft and that of the stock being fitted so as to joint perfectly all round, and the shield closely adhering to the tree in every part, it is kept on by a ligature; and the edges of the wound are covered with grafting-wax or clay. It is a remarkable fact, which some are, perhaps, not aware of, that the wood formed under a piece of bark inserted in this manner, even though that bark be without a bud or eye, will be the wood of the tree from which the shield was taken. In this way several different kinds of wood might be formed on one tree, without introducing a single leaf belonging to those different woods. The portion of wood introduced will always be limited in diameter to the size of the portion of bark put on.

2. *Budding with a Bud or Eye, and a circular Escutcheon; Greffe en Ecusson par Inoculation.*—With the point of a grafting-knife, or rather with that of a penknife, cut a small bud out of the tree to be propagated, leaving a narrow rim of bark round it, and taking, at the same time, a portion of the wood, which is retained. A hole is made in the stock, of the same size as the bud and its rim, and of a depth equal to the length of the piece of wood left on. The whole is adjusted so that the bud, with its bark and wood, fills up the wound exactly; and the edges are then covered with grafting-wax. This mode of budding is employed to equalize the flower-buds over a tree, by removing some, from where there are too many, to those parts of the tree where there are too few.

3. *Escutcheon Budding with Wood under the Bark; Greffe en Ecusson boisée, (fig. 6.)*—To procure the escutcheon, a deep and

transversal incision is made above a healthy and vigorous bud; then, by withdrawing the

blade of the grafting-knife, and entering it rather higher than this cross cut, a narrow strip of bark, three or four lines broad, by 1 in. or 1½ in. long, is taken away, terminating in a point

at the bottom. The eye should be situated about a third from the top, and the stipules, or other appendages that sometimes accompany the petiole, as well as prickles, &c., must be taken off with caution. With the point of the grafting-knife, the wood of the escutcheon is then taken out, leaving a small piece immediately under the eye, and about a third of the length of the escutcheon. The bud, thus prepared, is inserted in the stock, and then tied as before. This mode of budding is that most generally used in European nurseries.

4. *Escutcheon Budding, with a growing Bud; Greffe en Ecusson avec un Œil poussant.*—The escutcheon is cut, and placed in the same manner as by the preceding method; but, as soon as it is inserted, the head of the stock is cut off, and all the buds that push from it, except that from the escutcheon, are rubbed off as they appear. This mode of budding, when done in the spring, has the great advantage of forcing the bud to develop itself immediately, thus gaining a year. However, it sometimes happens that, if the bud does not take, the sap of the stock not being able to find a channel, from all the shoots being rubbed off as they appear, the stock, or at least a great part of its length, dies of repletion. When done in the month of August, this mode of budding seldom succeeds, because the young shoot, not having time to ripen, perishes with the frost, and often causes the death of the stock.

5. *Escutcheon Budding, with a dormant Bud; Greffe en Ecusson avec un Œil dormant.*—This mode is similar to the preceding; but it is performed in August, and nothing is cut away from the stock till the following spring, in order to prevent the development of the bud before that season. Though longer before it takes effect, this mode of budding is more certain to succeed than the preceding method. It has also the merit of not hurting the stock, if it does not take. The inhabitants of Vitry, who carry on the greatest commerce in fruit trees in the neighborhood of Paris, use it almost exclusively. This mode is that generally used in the British nurseries.

6. *Escutcheon Budding, without the Wood; Greffe en Ecusson dénuée de Bois.*—According to this mode, all the wood is taken away except a speck immediately under the bud; to the life of which bud, however, that speck is essential. The rest of the process is as usual. Besides being very suitable for orange trees, this mode of budding is used for all trees having hard wood, such as myrtles, hollies, and all analogous species, whether indigenous or exotic. It can be done either with the growing bud or dormant bud.

7. *Escutcheon Budding, with Pincers; Greffe en Ecusson à Emporte-pièce.*—A pair of pincers ought to be made on purpose, with which a piece of bark is taken off the stock. With the same instrument, or with the blade of the grafting-knife, an escutcheon or plate of bark, having a vigorous eye in its centre, is taken off a young shoot of the tree to be propagated. It must

be exactly of the same size as the wound made in the stock, in order to fill it with the greatest precision. When it is properly fixed, it is supported by means of grafting-wax or soft wax. This method is excellent for budding old trees, the thick and rugged bark of which is not suitable for the ordinary modes.

8. *Escutcheon Budding; with the Eye turned downwards; Greffe en E'cusson a Rebours.*—The escutcheon is cut in such a manner that the point of the eye, when placed on the stock, is turned downwards, whether the incision in the stock is made in the usual manner, or like a T reversed, thus, L. By this method, the buds are forced to grow in a direction opposite to that which they would have taken naturally; but they soon resume their usual position; and the desired end, viz., that of increasing the size of the fruit by stagnating the returning sap, is thus by no means attained.

9. *Reversed Escutcheon Budding; Greffe en E'cusson renverse, (fig. 7.)*—The escutcheon is prepared in the form of a triangle; but, instead of bringing it to a point under the eye, it is pointed above it. It will

be perceived that the incision in the bark of the stock must be also reversed; that is to say, instead of being in the form of an upright T, it must be like a T turned upside down, as in the figure. To effect this, the longitudinal incision is made above the transversal one, instead of making it below it. It is finished with ligaments and grafting-wax, as the preceding modes. In comparatively cool and moist climates, like that of Britain, the grafting-wax may be dispensed with in such cases as this and the three or four preceding ones. This manner of budding is almost the only one used in the south of Europe, particularly at Genoa and at Hieres, to multiply orange trees. It is also suitable for the propagation of trees having abundant and gummy sap; and it might probably be advantageously employed to secure the success of buds on resinous trees.

10. *Budding resinous Trees; Greffe en E'cusson d' Arbres resineux, (fig. 8.)*—An incision is made in the form of T, as if for an ordinary bud, in the bark of the stock.

A double incision is then made obliquely, about two lines or two lines and a half from the upper part of the T: this incision should penetrate the bark to the thickness of nearly a line, or so as to reach the soft wood. This mode of budding succeeds not only on resinous trees, but also on all those that have a gummy and very abundant sap.

11. *Covered Budding; Greffe en E'cusson couvert, (fig. 9.)*—The bud is prepared as usual; but, when it is inserted in the stock, instead of a ligature, the lines of junction are covered with grafting-wax: a

piece of bark is then taken from another tree, and, a small hole being made in the middle of it, it is placed on the escutcheon, so as to cover the whole of it except the bud, which appears through the hole, as in the figure. A bandage is then put over the bark, to keep the whole toge-

ther. This mode of budding is rather too intricate for ordinary purposes; but it may be worth adopting for rare and delicate trees.

12. *Budding with a square Escutcheon; Greffe en E'cusson carre.*—Three incisions are made in the stock, one transversal, and the two others longitudinal, beginning on each side of the horizontal one, and descending perpendicularly four or five lines. They are to be four or five lines apart, and to represent a long square, the bottom line of which is wanting. This square strip or plate is raised and turned down. A square escutcheon, provided with a good eye, is then cut from a branch of the tree which is to be propagated, exactly of the same size as the plate stripped down the stock; and it is applied to the incision, which it must cover with the greatest exactness. This being done, the plate of bark, which was hanging down on the stock, is raised, and the escutcheon covered up to the eye; the line of junction is then coated with grafting-wax, and the whole is tied like other buds. It appears that this mode of budding was much used formerly, and that it succeeded perfectly; but, as it is rather tedious in the execution, it is now seldom employed.

[To be continued.]

[From the National Intelligencer.]

PEACH TREES.—This modest and beautiful tree, the parent of one of the most delicious of all fruits, is, if properly managed, perhaps the most easily cultivated and preserved of all fruit trees. To sustain these observations, I mention my own experience. On a rented farm, and on which I resided near ten years, I found but one good thriving peach tree when I took possession, and only a few stocks of that tree in any condition. Regarding it a duty which every man owes to society, to plant fruit trees if in his power, I commenced raising the peach from the stone, and persevered in that plan during nine seasons, and left a considerable number of the very finest peach trees in the highest state of health when I removed.

There is no one other fact in natural history, of the truth of which I am more convinced, than that the peach tree would, in any part of the middle or southern States, flourish, if three rules were observed:

1st—Plant the seed annually, so as to have new plants to set out annually; or, what is much better, plant the seed where the tree is to stand.

2nd—Whenever the tree commences to decay, cut it down as near the ground as possible.

3rd—Plant the peach tree in your best soil, and work the ground around where it stands.

In the public prints, we see this season, from all quarters, accounts of the destruction of the peach tree by the frosts of last winter. In some cases the body of the tree is said to be killed, while the roots are living.

The peach tree is evidently a native of a much warmer climate than that of the central United States. In Louisiana, Mississippi, and Florida, I have seen it in flower, and in leaf partially, at every winter month. It is of course in the southern section of the United States an imperfect

evergreen. In all situations and climates where I have seen it growing, from N. lat. 29 deg. to 45 deg. it is a tender tree and demands care; but with care and skill, there is no other tree which yields to man a more grateful and certain return.

Similar to all organized beings, when wounded by any adverse cause, the peach tree exerts the principles of life, or more distinctly the principles of self-preservation, and, in the very case of injury by frost, this operation of nature becomes so striking as to arrest attention from the most casual observer. In the National Intelligencer of May 28th, 1835, quoting from the Wyoming Republican, I have read the following:

"A few weeks since we mentioned that the peach trees in this neighborhood were generally killed by the coldness of the winter. Upon close examination, we find the roots of the trees are alive, and some of the limbs of many are putting out leaves; tho' in general the tops are dead."

Now, from actual experience I am fully convinced, that, if those trees, the roots of which are alive, and exerting their resources to save the branches, were relieved by amputation of the whole tree to within one, two, or three inches of the ground, that numerous fine healthy young stems would be seen rising, and which, in two, or at most three years, would be loaded with fruit. This statement is made from actual experiment, within twenty miles from your office, and never failed in a single instance. The preservation of the tree in this case is very greatly enhanced by keeping the ground loose and clear of weeds near the roots.

Let me, in conclusion, say to the Farmer, plant the seed of peach annually, keep the ground cultivated around the root, and when, by any means, the stock is found in a decaying state, cut it away, and leave the root to expend its resources on the production of new scions, and one of the most ornamental trees and most delicious fruits may be secured with almost unerring certainty. A TRAVELLER.

PROPAGATION OF THE SILK WORM.—Last year, on the 4th of July, CHARLES DYER, Esq., of this city, had four silk worms. From these four and their progeny, he had three complete crops of cocoons. There are now feeding, at the cocoonery of the Valentine Company in this city, about SEVEN HUNDRED THOUSAND worms, all the product of the four which Mr. Dyer had on the 4th of July, 1834.—[Providence Journal.]

JULY 4—JULY 10, 1835

OBITUARY.

The event which latterly has held in such deep suspense "the hopes of the good, and the fears of the wise," has at length occurred—JOHN MARSHALL, Chief Justice of the United States, is dead! We know of no form of words, whereby admiration and regret could add emphasis, to the simple enunciation of this melancholy fact.

The Chief Justice died in Philadelphia on Monday afternoon. He had gone to that city to seek medical aid—but the most eminent talent and the most assiduous care, failed to prolong a life, already protracted beyond the ordinary term of man's years—and of which the whole course, from early manhood to the day of his death, was passed in most arduous public services.

"Mr. Marshall," we borrow from the Philadelphia Inquirer, "was born in Virginia, on the 24th of September, 1755; and as early as the summer of 1775, received a commission as lieutenant of a company of Minute men, and was shortly after engaged in the battle of the Great Bridge, where the British troops, under Lord Dunmore, were repulsed with great gallantry. He was subsequently engaged in the memorable battles of Brandywine, Germantown, and Monmouth; and in 1780, obtained a license to practice law. He returned to the Army shortly after, and continued in the service until the termination of Arnold's invasion.

In the spring of 1783, he was elected a member of the State Legislature, and in the autumn of the same year, a member of the Executive Council, and married in 1783. In 1788 he was elected as Representative of the city of Richmond in the Legislature of Virginia, and continued to occupy that station for the years 1789, 1790, 1791, and upon the recall of Mr. Monroe, as Minister, from France, President Washington solicited Mr. Marshall to accept the appointment as his successor, but he respectfully declined. In 1799 he was elected and took his seat in Congress, and in 1800 he was appointed Secretary of War.

On the 31st of January, 1801, he became Chief Justice of the Supreme Court of the United States, which distinguished station he continued to fill with unshaken dignity and pre-eminent ability, until the close of his mortal career. His biographer eloquently observes—"What indeed strikes us as the most remarkable in his whole character, even more than his splendid talents, is the entire consistency of his public life and principles. There is nothing in either which calls for apology or concealment.—Ambition never seduced him from his principles—popular clamor never deterred him from the strict performance of his duty. Amid the extravagance of party spirit, he stood with a calm and steady inflexibility—neither bending to the pressure of adversity, nor bounding with the elasticity of success. He lived such as man should live, by and with his principles. If we were tempted to say by one word in what he excelled all other men, we would say, in wisdom; in the union of that virtue, which ripened under the hardy discipline of principles, with that knowledge, which constantly sifted and refined its old treasures, and as constantly gathered new.—The Constitution, since its adoption, owes more to him than to any other single mind, for its true interpretation and vindication. Whether it lives or perishes, his exposition of its principles will be an enduring monument to his fame, so long as solid

reasoning, profound analysis, and sober views of government shall invite the leisure, or command the attention, of statesmen and jurists."

He died calmly and tranquilly, surrounded by three of his children and many valuable friends.—The blow was not unexpected, and he was fully prepared. But a few days since he penned an inscription for his tombstone.

The subjoined sketch of this lamented individual will—now that our eyes are to look upon him no more—be read with renewed interest. It is accurately descriptive and just.

Chief Justice Marshall,

BY WILLIAM WIRT.

The Chief Justice of the United States is in his person tall, meagre, emaciated, his muscles relaxed, and his joints so loosely connected as not only to disqualify him, apparently, for any vigorous exertions of the body, but to destroy every thing like elegance and harmony in his air and movements.—Indeed in his whole appearance and demeanor,—dress, attitude and gestures—sitting, standing or walking—he is as far removed from the idolizing graces of Lord Chesterfield, as any other gentleman on earth. To continue the portrait: his head and face are small in proportion to his height; his complexion swarthy; the muscles of his face being relaxed, gives him the appearance of a man of 80 years of age, nor can he be much younger. His countenance has a faithful expression of great good humor and hilarity; while his black eyes, the unerring index—possess an irradiating spirit, which proclaims the imperial power of the mind that sits enthroned within.

This extraordinary man, without the aid of fancy, without the advantage of person, voice, attitude, gesture, or any of the ornaments of an orator, deserves to be considered as one of the most eloquent men in the world; if eloquence may be said to consist in the power of seizing the attention with irresistible force, and never permitting it to elude the grasp, until the hearer has received the conviction which the speaker intends.

As to his person, it has already been described. His voice is dry and hard, his attitude in his most effective orations was often extremely awkward, as it was not unusual for him to stand with his gestures proceeding from his right arm, and consisting merely in a vehement perpendicular swing of it from above the elevation of his head to the bar, behind which he was accustomed to stand.

As to fancy, if she held a seat in his mind at all, which I very much doubt, his gigantic genius tramples with disdain on all her flower decked plants and blooming parterres. How, then, will you ask, with a look of incredulous curiosity—how is it possible that such a man can hold the attention of an audience enchained through a speech of an ordinary length? I will tell you.

He possesses one original and almost supernatural faculty, of developing the subject by a single glance of his mind, and detecting at once the very point on which the controversy depends. No matter what the question, though ten times more knotty than the "gnarled oak," the lightning of heaven is not more resistless than his astonishing penetration. Nor does the exercise of it seem to cost him an effort. On the contrary, it is as easy as a vision. I am persuaded that his eyes do not fly over a landscape and take in its various objects with more promptitude and faculty, than his mind embraces and analyzes the most complex subjects.

Possessing while at the bar this intellectual elevation, which enabled him to look down and comprehend the whole ground at once, he determined, immediately, and without difficulty, on which side the question might be most advantageously approached and assailed; in a bad cause, his art consisted in laying his premises so remotely from the point directly in debate, or else in terms so generous and specious, that the hearer seeing no consequences which could be drawn from them, was just as willing to admit as not; but his premises once admitted, the demonstration, however distant, followed as certainly, as cogently, and as inevitably, as any demonstration in Euclid.

All his eloquence consists in the apparently deep self-conviction and emphatic earnestness of his manner; the correspondent simplicity and energy of his style; the close and logical connection of his thoughts, and the easy gradations by which he opens his lights on the attentive minds of his hearers.

The courts and the bar in Philadelphia are making preparations to do honor to the memory of this great Jurist—and in this State, as in every other, we presume, as the respective courts meet, there will, it cannot be doubted, be a spontaneous and earnest expression of respect, and admiration, for so brilliant and so useful a career as that just closed.

To John Marshall belongs, and will belong perennially, the glory of having giving form, and fashion, and precise interpretation, and fixed and definite applicability, to the general provisions of that most perfect of human instruments, the Constitution of the U. S. Living with, and sharing the councils, as in the revolutionary struggle he had shared the perils of, the wise and patriotic men who framed it, and fitted by early studies, by practical experience in public life, and above all, by the rare endowment of an analytical and honest mind, which knew how to seek out truth, and which nothing other than truth would satisfy—to comprehend, to elucidate, and to establish the great views and aims of that Constitution—he has, by his decisions and opinions as Chief Justice, made plain what seemed confused, unravelled what was intricate. and—without seeking to extend, or consenting unduly to limit, the authority and jurisdiction of the Court over which he presided, but by carrying out unambitiously yet unflinchingly, the purposes of its organization—he has shown it to be the safest, the wisest, and the most efficient bulwark, alike of State rights and of rightful Federal authority.

At any moment, the loss of such a man would be deplored; but at this moment, when the possible successors of such a name, and to such a station occur to the mind, regret is indeed unmitigated by aught of hope.

U. S. Military Academy.

Report of the Board of Visitors invited by the Secretary of War to attend the General Examination of the Cadets of the United States Military Academy.

Hon. Lewis Cass, Secretary of War.

SIR:—The undersigned, having attended the General examination of the Cadets of the United States Military Academy, as a Board of Visitors, submit the following Report as the result of their observations.

The Board directed their inquiries to the course of instruction, both military and scientific, to the internal police, discipline, and fiscal concerns of the Institution. In making these inquiries, every facility was afforded by the Superintendent and members of the Academic Staff. In order that these inquiries might be prosecuted with greater advantage, Committees were appointed by the Board, with instructions to inquire especially into the portion of the foregoing subjects referred to them respectively, and to report the result of their observations.

The reports of those Committees, which are herewith transmitted, will convey to you much information in detail, which could not conveniently be embodied in this report.

As this is professedly a Military Institution, the attention of the Board was first directed to the course of military instruction. Although this branch embraces a wide field, it is intended to speak of it as limited to Engineering, Artillery, and Infantry Tactics.

Engineering is divided into two branches; Civil and Military; and in connection with the latter, is taught the Science of War, so far as it relates to the attack and defence of military positions, and the providing of defensive means for an army operating in the field.

In the course of Civil Engineering, is taught the properties, preparations, and use of materials of construction; elementary parts of buildings, and the art of construction generally, including decorative architecture; the manner of laying out and constructing roads, the construction of the various kinds of bridges, the general principles which regulate the removal of obstructions that impede the navigation of rivers; the survey, location and con-

struction of canals and railroads; and the formation of artificial, and the improvement of natural harbors. This branch is taught to the first, or graduating class, by lectures, and a series of drawings and notes, prepared by the Professor from the best authorities, and lithographed at the press belonging to the Institution, under the title of "Outlines of the Course of Civil Engineering." Drawings, illustrative of the prominent parts of the subject, are executed by the Cadets; and these exhibit great neatness of execution, as well as much precision in detail.

Next in order is the course of Military Engineering.

This comprises Field and Permanent Fortification. In the first, are taught to the same class, the principles which regulate the construction of field intrenchments; the different kinds of lines; batteries for the various kinds of ordnance; the armament of intrenchments, with reference to the attack and defence, enclosed and detached works; defence of posts; and the construction of military bridges; permanent fortification, including a complete description of the bastion front; the attack and defence of the same; a critical examination of the principal systems of fortifications; the construction and armament of a fortress; the hydraulic works used in the defence of military positions; mining; the principles of defilement, and their application to works constructed for inland and maritime defence. Military Engineering is taught from a text book, and from notes prepared with judgment and skill, by the Professor; the whole being amply illustrated by drawings, executed by the students, under the immediate supervision of instructors.

To the professional ability of the Professor to whom this department is confided, the very able and satisfactory manner in which his pupils acquitted themselves in the various parts of their course at the black board, in presence of the Visitors, afforded the most pleasing and ample testimony.

No changes, either in the course of study or organization, are at present contemplated, nor are any deemed necessary. The Board, however, would recommend the continuance of small appropriations of money, by Congress, for the purpose of providing the department with such works and models as the Professors may from time to time require.

Instructors are given to the Cadets of the first class in Artillery Tactics, during the encampment, which usually commences in June and terminates on the first of September following. During this time, they are required to recite upon a system of Field Artillery, at the same time that they are taught a course of Pyrotechny, Mortar exercises and Target practice, with guns of various calibre, as well as mortars and howitzers. Cadets of the other classes are also taught the drill of Field Artillery during the suspension of the other academic studies.

It is thought by the officer at the head of the Department, that the time allowed for recitation is insufficient, and that much which ought to be studied thoroughly is necessarily passed over rapidly.

In our country there is no establishment provided by law especially for instruction in Artillery. All the education our officers receive in this branch of study is, with the exception of the mere drill of an artillery garrison, obtained at this place. This deficiency would seem to suggest the importance of placing this department of the Academy upon a more enlarged and permanent basis.

It is the opinion of the Board, that it would be greatly to the advantage of this course of instruction, if a permanent assistant were attached to it, instead of the mode now in use of detailing Cadets from the graduating class.

In connexion with this subject, the Board would remark, that the moving of ordnance on the field, by the bodily exertions of the Cadets alone, is a requisition upon them of great severity, and is at the same time obnoxious to the objection, that it keeps the Cadets entirely unskilled in the only mode of using the field piece employed in actual service. The Board would, therefore, suggest the propriety of procuring a number of horses sufficient for Artillery exercise, and also for instruction in Cavalry tactics.

The same horses would be used for both purposes, and the number required would not exceed forty.

Cavalry Tactics have never been taught at the

Academy. Cavalry, as an arm of national defence, is confessedly of great importance. It is submitted whether instructions in that branch might not be advantageously added to the course of instruction at this Institution.

The Ordnance Stores furnished for the year, are good in quality and sufficient in quantity. Some field pieces and guns of different calibre are wanted to render this department complete, which are particularly detailed in the report of the Committee on this subject.

On drill, and in firing in the field, the Cadets exhibited a thorough knowledge of the manoeuvres and evolutions in this important arm of service; and in their drawings and mathematical demonstrations at the black board, they evinced high proficiencies in the theory and practice of gunnery. Their target firing and accuracy of throwing shells, are very commendable, and afford unequivocal evidence of great zeal and ability on the part of the instructor, for which he is entitled to much credit.

The corps of Cadets, organized as a battalion of infantry, exhibits on the field a perfect knowledge of infantry tactics, and performs all the evolutions of the line and of the battalion with facility and accuracy. Their appearance in dress, in the condition of their arms and accoutrements, as well as in soldier-like bearing, is highly gratifying, and deserves much commendation, whilst it reflects much credit on the experienced officer who commands them.

With regard to the course of study in the other branches which are taught, agreeably to the regulations of the institution, the Board was well satisfied with the abilities and zeal of the professors and their assistants.

Besides the branches already mentioned, the Cadets of the first, or graduating class, were examined on Moral and Political Science, and on Mineralogy and Geology, on all of which they exhibited attainments that could only be the result of much attention on their part, aided by skill and perseverance on the part of the Professors and their Assistants.

In Moral and Political Science, the first class was subjected to a satisfactory examination. The familiarity they evinced with the several systems of ethics propounded by distinguished masters at different periods, showed that their minds had been effectually directed to the distinguishing characteristics of those systems, and their relative merits closely compared by them and familiarly understood. The examination on the subject of Government and Constitutional Law, were highly gratifying, with room, it is true, for slight shades of difference in opinion; on the latter topic, the discussions and replies of the class were such as showed a just comprehension of the nature and objects of civil government in general, of the peculiar and unique and happy system under which they live; qualifying them at once for participation in the pursuits of civil and political life, and teaching them duly to appreciate the blessings of those institutions, which, as soldiers, they may be called upon to defend.

The second class was examined on Natural and Experimental Philosophy, on Chemistry, and Drawing. On these branches, the proficiency of the Cadets was quite creditable to themselves and to their instructors. The knowledge which the pupils seem to have acquired in the important branch of Chemistry, not only of its general principles, but of their application in detail was gratifying. The specimens of Drawing by the Cadets, exhibited to the Board, showed a practical acquaintance with this branch, which demonstrated that they are fitted at once to apply their acquirements to purposes of practical utility.

The third class was examined in Mathematics, in the French Language, and Drawing.

The fourth class in Mathematics and the French Language.

It has often been remarked, that in no school is the mathematics more thoroughly taught than at this Institution. The correctness of this remark was quite manifest during the present examination, whenever mathematics or any other branch dependent on that science was under consideration.

The examinations on the French language were very satisfactory. To those acquainted with the language, there appeared, by the course of instruction, to be imparted to the student a thorough knowledge of the principles of the language.

Some of the members of the Board had an op-

portunity of witnessing the proficiency of the Cadets under the instructions of the Sword Master. It was thought to be quite creditable. Whilst the instructions of the Sword Master secure to the officer and soldier the best means of personal defence, the exercise connected with them is well fitted to improve the health, and to impart to the muscular system tone and vigor.

As connected with the course of study, the Board has thought proper to remark, that a good Library, a Chemical and Philosophical Apparatus, are essential aids in imparting scientific instruction. It is believed an important benefit would be conferred on the institution, by adding to the library some of the periodical works which contain the earliest, and, at the same time, the most learned dissertations upon the improvements of the day.

The situation of the Professorship of Chemistry, it is thought, might be placed on a better footing. At present it is subsidiary in every respect. It is recommended that it be placed on an equality with the independent professorships, and that there be two assistants, one of whom should be the Professor of Mineralogy. The whole course of study as conducted, it is believed, is well fitted to create a fund of information which cannot fail to be of inestimable value to our country in a civil as well as military point of view.

The attention of the Board was directed to the course of Religious instruction. This course is necessarily of vital importance. During the present visitation, the Chaplain to whom this department is entrusted, has been under arrest. There was, therefore, no opportunity of witnessing the manner in which the duties belonging to this department are performed. The importance of the duties to be performed by the Chaplain, has induced the Board of Visitors to recommend that the Secretary of War institute an inquiry into the causes which have led to a suspension of the performance of those duties.

With regard to the Internal Police it is entitled to high approbation. The condition of the hospital is fully suited to the object of securing to the Cadets all the comforts and all medical aid that they can require in ordinary cases of indisposition. Clean, well ventilated, and properly attended by nurses, nothing need be added on these heads; recent circumstances, however, have suggested the propriety of enlarging the number of surgical instruments.

The South Barrack, which is the oldest building of the kind at this post, is badly constructed. The rooms are too small, and they are injudiciously disposed. It is recommended that they be rebuilt.

Both barracks present an air of cleanliness and order that reflects credit on all concerned.

The Steward's Hall, where the Cadets mess in common, was visited. It was found that the Cadets are supplied with good and wholesome food.

A building for a Chapel has been commenced; and it is thought will be completed this year.

The Store House is an old and very insecure building, and altogether unfit for the use to which it is applied; a new one is recommended for the safe keeping of the stores deposited here.

The fiscal concerns of the institution were brought to the notice of the Board. The disbursements are found to be made in accordance with the appropriations made, and a system of order and economy prevails. A building for military and other exercises, so requisite for the successful prosecution of military knowledge during the inclement season of the year and to the health of the Cadets, has been commenced under the appropriation for that purpose.

An improvement is recommended in the apartments appropriated to the use of the Chemical Laboratory, Library and Philosophical Apparatus. They are too small and exposed to danger in making chemical experiments.

The teacher of Drawing is entirely destitute of the convenience necessary to the practice, study, and of course improvement in his profession. The building of an apartment for that purpose is recommended, the estimate expense whereof will not exceed eight hundred dollars.

In the accounts of the Treasurer and Quartermaster the expenditure appears to be rigidly confined within the appropriation. The whole fiscal arrangement meets the entire approbation of the Board. The attention that is paid to economy in all the details of the Institution is very satisfactory. There remains in the Treasury an unexpended

balance of the appropriation of last year of eight thousand dollars.

Upon the whole the Board is of opinion that the Institution is well conducted; that the objects to be attained by its continuance are of very great importance to the community. Knowledge is obtained by means of this Institution which is indispensable to the successful conduct of military affairs. Not only is the knowledge imparted to those educated here, valuable in time of war, but should a state of war be looked upon as remote, the knowledge acquired is scarcely less valuable in time of peace, when applied to the prosecution of the various improvements which are so rapidly developing and enlarging the resources of our country. But the hope that peace shall be perpetual should not be indulged to our detriment. The means most essential to the resistance of aggression should always be within our reach. The humiliating disasters, the waste of life and treasure, that marked the commencement of the late war, for want of a knowledge of what should be deemed the elementary principles in the science of war, are still fresh in the recollection of many. This Institution, it is believed, is well fitted to obviate the recurrence of such calamities, from the same cause. At an expense less than is requisite to keep in commission a frigate of the largest class, knowledge of the science of war, in principle and in practical detail, is imparted to a sufficient number of citizens of our own country, to enable us, in any emergency, to conduct our military operations on a footing of equality with the most skillful enemy. When it is considered that success in war is slightly dependent on either the numbers or courage of the parties, but is most generally the result of the scientific and skilful combinations of causes, the effect of which is foreseen and calculated almost with the precision of a mathematical problem, it would be a source of the most painful reflection, that a country, justly proud of its freedom and liberal institutions, should, for want of appreciating the knowledge necessary to the defence of that freedom and those institutions, permit itself to be placed at the mercy of the enemies of all liberty and liberal institutions. It cannot be denied that those governments most hostile to liberty at the present day, are most ready to appreciate, and to appropriate all the aids that can be derived from science, and applied to the art of war. How important that those countries blessed with freedom should keep themselves on a footing of equality, not in the largeness of their armies, but in the knowledge necessary to the formation of armies, and to direct them, when formed, with efficiency. The knowledge imparted at this institution to the children of our own citizens, selected from every part of the country, is so indispensable to our security, that to dissolve it without providing a substitute possessed of advantages equal or preferable, would seem like retrograding from civilization towards barbarism; and well calculated to endanger our national independence.

(Signed.) P. V. DANIEL,

President of the Board of Visitors.

#### SUMMARY.

The venerable JAMES GIBSON, the hero of Stony Point, the respected and honored of all parties, expired at his residence in Richmond, Virginia, on Wednesday morning last, after a lingering illness.

We understand that the President of the United States left this City yesterday, in the Steamboat Columbia, for the Rip-rap, (Fort Calhoun,) where he proposes to recreate and recruit his health for a week or two.—[Nat. Intel.]

A letter writer from the White Sulphur Springs of Virginia, states that Major Barry, the Post Mas-

ter General, was a visitor there on the 23d of June, and that he was in very feeble health.

The Norfolk Beacon states that orders have been received at the Navy Yard, Gosport, for the immediate fitting out of the North-Carolina 74.

[From the Globe.]

OFFICIAL.

NAVY DEPARTMENT, 3d July, 1835.

The Board of Examination recently convened at Baltimore, composed of Captains—

HENRY E. BALLARD, President.

A. J. Dallas,

Wm. Compton Bolton, } Members.

Alex. Claxton, and

Laurence Kearney,

has closed its duties.

The following is a list of the Midshipmen who passed, arranged in the order assigned them by the Board:

Class 1827.

M. G. L. Claiborne.

Class 1829.

- |                        |                           |
|------------------------|---------------------------|
| 1 Oliver H. Perry,     | 16 George Wycke,          |
| 2 Charles W. Morris,   | 17 Octavius Fairfax,      |

| 14 Thomas Budd,        | 29 Charles Thomas.        |
| 15 And. F. V. Gray,    |                           |

FINANCES OF CONNECTICUT.—According to the annual account of the Comptroller of the State of Connecticut, the whole expenditure of the Commonwealth, including Legislature, Judges, State Prison, &c. was last year \$74,015—and the receipts (excluding a balance in the treasury of \$13,443) were \$78,258. The public funds of the State (exclusive of its very large School Fund) are about \$400,000 in bank stock; its public debt about seven hundred dollars!

The Detroit Journal of June 30th, says—It is cheering to state, for the information of our distant friends, that the general health of our city has rarely been surpassed: and never have our streets presented a more gratifying exhibition of business, enterprise, and progressive improvements, than at the present moment.

DIVIDENDS.—The following Marine and Fire Insurance offices made their semi-annual dividends yesterday:

Neptune office	7 per cent.
Ocean " "	6 per cent.
New York " "	5 per cent.
Union " "	3 per cent.
Howard " "	4 per cent.

EFFECTS OF COMBINATIONS.—The Miners Journal states that since the turn out of the Boatmen, we understand that several of the largest shippers of Coal in this region, are making arrangements to have built a sufficient number of boats to carry their own Coal to market.

ROYAL AND NOBLE TRAFFICKERS.—In a recent book of travels, or rather book for travellers, published in England, "The Road-book from London to Naples," the following statements are made:

Near Cumæ is the Lake of Fusaro, where the pleasure of the excursion, to some travellers, finishes with a feast of oysters, for which this lake is famous. It belongs to a very distinguished oyster-monger—the King of the two Sicilies—whose agents open the fish and supply the visitors.

They do strange things in this way in Italy. At Rome, the Cardinal Doria used to be the milkman to those who chose to send to his palace for this necessary article to the tea-drinking English; and at Naples, the only good buttermilk is his majesty; and those who wish to have this article genuine send to court for it, whence it is issued impressed with the royal arms. His majesty is also the chief, or only dealer in gunpowder, salt, tobacco, &c. &c. &c.

THE LITERARY SOUVENIR FOR 1835, by *Mart A. Watts*, of which the usual supply was despatched to this country in the packet ship *Sovereign*, and shipwrecked, has since been received by *Wiley & Long*—at least a few copies of it. The engravings, the paper, and getting up of the book—so far as the eye is concerned—and we have had no opportunity for any other examination, are exceedingly attractive.

PROGRESS OF THE ARTS.—The National Academy closed its exhibition of original pictures, by native artists, on the 4th inst.; and it is with satisfaction we learn and record the two encouraging facts—that the receipts from this exhibition exceeded by a thousand dollars those of any previous one—and that, with very few exceptions, every picture that was on sale, was bought at the artist's own prices. Among them were three by *MOUNT—the Sleepy Hollow*, by *COLL*—and several others. This result is both gratifying and encouraging.

In an account of the present exhibition at Somerset House, we find these notices of two pictures, which may be called American. The one from its subject *Columbus*, the other from its artist *Leslie*.

"Christopher Columbus explaining the project of his intended voyage for the discovery of the New World, in the convent of La Rabida." D. Wilkie, R. A.

"A stranger travelling on foot, accompanied by a young boy, stopped one day at the gate of a convent of Franciscan friars, dedicated to Santa Maria de Rabida, and asked of the porter a little bread and water for his child: while receiving this humble refreshment, the guardian of the convent, friar Juan Perez de Marchena, happening to pass by, was struck with the appearance of the stranger, and observing from his air and accent that he was a foreigner, entered into conversation with him." That stranger was Columbus.

"The conference which followed was remarkable for opening a brighter prospect in the fortunes of Columbus, and forms the subject of the picture in which he is represented seated at the convent table, with the prior on his right, to whom he is explaining, on a chart, the theory upon which his long contemplated discovery is founded. At his left is his son Diego, with a small Italian greyhound at his feet, supposed to have accompanied them in their voyage from Genoa.

"At the other side of the picture, resting on the table, is the physician of Palos, Garcia Fernandez, who from scientific knowledge, approved of the enterprise, and whose testimony has recorded this event. Behind him, with the telescope in hand, is Martin Alonso Pinzona, one of the most intelligent sea captains of his day."

Such is the subject of the picture, and it may be considered the triumph of Wilkie's in the present exhibition, and one that ranks very high in art.—The expression of Columbus is truly noble and intelligent, dignity and mildness are in every lineament. At the left of Columbus is his son Diego, holding a small Italian greyhound, which reclines at his feet. In the back ground is introduced the head of Pinzona, whose expressive eye denotes the suppressed jealousy lurking in his bosom, at the same time giving a reluctant approbation to the plan of the great navigator. The other characters are all in accordance with the subject, and as far as conception in color and composition extend, this picture may rank among the grand historical, and be classed among the finest productions of the British school.

"Gulliver's Introduction to the Queen of Brobdingnag." C. R. Leslie, R. A.—This picture represents the point of time when the little Gulliver is presented to the gigantic Queen of the Brobdingnagians, surrounded by her maids of honor. The captain in the back ground is receiving the money which the Queen pays for the purchase of the diminutive curiosity. Gulliver is on the table embracing with fervent devotion the tip of her Majesty's little finger. We think the whole of this picture is a misconception. The artist has not conquered the difficulty with which the subject evidently labors, namely, to make the women Brobdingnagians without making a Lillipution of Gulliver. As a painting it has the usual superior style of this artist's masterly touch and freedom of exe-

cution, with great harmony of coloring—but still we must confess the representing Gulliver among the Brobdingnagians is quite a failure.

**ROYAL ASSOCIATE IN THE TEMPERANCE CAUSE.**—We find it stated in the Paris papers of 8th May, that *Bernadotte*, king of Sweden, had become a member of the Temperance Society at Stockholm. According to the regulations of that Society, when a man becomes a sot, his name is posted up at the church doors, and prayers are offered up by the congregation for his reform.

Should not the N. Y. State Temperance Society—that "moral colossus," as we have seen it happily called—elect this King who thus, the first of his order, lends the influence of high name and station to such a cause, an honorary member?

The Nashville papers state that the United States Bank has ordered the office in that place to collect its old debts by the 4th day of March next, and to close its new business, founded on bills to be drawn on New Orleans, in anticipation of the growing crop, within six months from the first day of November next, thereby to enable the Parent Bank to withdraw its office from Nashville by the first day of May.

The committee appointed to ascertain the damage done by the Tornado in the village of Piscataway, New Jersey, report the amount at five thousand and fifty dollars. This is a very heavy loss for such a place.

[From the *Lynchburg Virginian* of Thursday last.]

**THE STORM.**—It is impossible to give any thing like a minute and detailed account of the ravages of the furious and destructive storm, with which we were visited on Saturday afternoon, 27th June. Our information from the country is entirely too partial and limited to admit of it. We have learned, however, that its first traces are discernible on the farms near the base of the Peaks of Otter, in Bedford county, (some 18 or 20 miles west of this place,) though in that immediate neighborhood the damage is comparatively trivial. Progressing eastwardly, with occasional deviations from a direct line, and gathering violence as they rolled onward, the clouds poured forth, from apparently inexhaustible magazines, showers of hail stones—or, more properly speaking, masses of ice,—stripping the orchards of their fruits, and the gardens of their vegetables—beating down the promising fields of corn level with the earth, the stalks mashed into a jelly and the fodder torn into shreds—sweeping off the wheat, rye and oats, as if the scythe of the reaper had passed over the fields, and scattering abroad the nearly ripened grain, as if the processes of curing and threshing had been a simultaneous work. In one word, the entire strip of country which was within the track of the storm—supposed to be a mile and a half in width, and probably from fifty to sixty miles in length—exhibits a most distressing scene of desolation and ruin.

In Lynchburg, all were sufferers, more or less. The gardens, many of which were highly cultivated, are entirely destroyed, with the exception of the few vegetables,—potatoes, onions and beets,—which were in a measure screened from the fury of the tempest by their subterranean mode of cultivation. Nearly every house in town lost a portion of its window glass.—It is supposed that not less than from 15 to 20,000 panes were shattered. A few chimneys were blown down, several dilapidated out-buildings prostrated, and many trees uprooted. Fortunately, however, no lives were lost, though several persons received severe contusions and bruises. Thousands of birds and domestic fowls were killed, and the trees in the forests and yards, in which the feathered tribe sought shelter, were divested of the greater portion of their foliage, and even their bark peeled off, as though they had been subjected to a moderate cannonade. The amount of damage done in this place and its immediate neighborhood cannot, of course, be at present estimated, with any thing like precision. It may, however, be safely stated at \$100,000—and we should not deem double that sum an extravagant estimate.

We can truly say that we never before beheld a

scene so awfully sublime and terrific as that presented by this storm, both in its approach and in its progress. There was but little thunder or lightning, but the descent of the hail was preceded, for several minutes, by a monotonous rumbling sound, resembling the bass tones of distant thunder, or the deep roll of the muffled drum—and reminding us of the ominous notes which precede the earthquake, apprising the unhappy victims of approaching death, too late to enable them to avail themselves of the warning. The clouds wore an unnatural aspect, tinged with a greenish hue, and rolling and pitching in the "void immense" with startling velocity and fury. Luckily, however, the wind was comparatively mild, except for a very brief space, when it exhibited that angry whirl, in which its tremendous power is most fearfully displayed. During that brief space the "war of the elements" so completely wrapped the largest objects in obscurity, that a house, within a few paces, was totally lost to sight.

**JOICE HETH.**—A negro slave is now exhibiting in this city, at the Washington Coffee House, who has attained the extraordinary age of 161 years. A visit which we paid her yesterday, has removed whatever doubts we may have previously entertained as to the facts confirmatory of this extraordinary instance of longevity—and of which we expressed our doubts some weeks since, when we saw the fact mentioned in a Cincinnati paper. She is certainly a curiosity, and is what we hardly supposed ourselves, a very agreeable and interesting sight. And what is very remarkable, she retains a vivid recollection of the scenes of her youth. As the proprietor is on his way to Philadelphia, his stay here will be short, consequently those who wish to avail themselves of the sight of a being who was living more than one hundred years previous to the revolution, should do so immediately. The proprietor is very attentive, and renders to the visitors every satisfaction.—[Pittsburg Adv.]

**TRINITY CHURCH, RICHMOND.**—The citizens of Richmond, Va., have already subscribed nine thousand dollars towards rebuilding Trinity Church, recently destroyed by fire in that town.

**BANK NOTE ENGRAVING.**—We have before us, a note designed for the Union Bank of this city, from a plate engraved by Messrs. *Casilear, Durand, Burton & Edmonds*, of this city, which strikes us as of the highest finish and execution. The female figures on the sides, and the lettering in the body of the note, are capital.

\* There are six India Rubber Manufacturing Companies chartered by the Legislature of Massachusetts—capitals from \$50,000 to \$100,000.

[From the *Boston Atlas* of Yesterday.]

The elegant steam packet *Independence*, destined for the Eastern route, arrived yesterday at 10 o'clock, in 30 hours from New York. Her burthen is 473 tons, and her accommodations for passengers, and furniture, are of the first quality. We are informed she will commence running to Bangor on Tuesday next. She can take out fourteen hundred people with safety.

**ISLAND OF CUBA.**—We have extracted from Havana papers the following official statement showing the imports, exports, and revenue of the Island of Cuba in the year 1834.

Imports,	\$18,563,300
Exports,	14,467,955
Imports from the U. States both in Spanish and American bottoms,	3,240,680
Exports to the U. States,	4,694,364

The number of Spanish and foreign vessels which visited the ports of the Island in 1832, amounted to 2026—797 of which were Spanish, 945 from the United States, 113 English, 58 French, and the remainder belonged to various European nations.

The tonnage of all these vessels amounted to 300,000 tons.

<i>Revenue of the Island.</i>	
Duties on imported and exported goods,	\$5,200,000
Taxes and other sources of revenue,	4,965,000

Total revenue, \$10,165,000

The Treasury of Havana, after meeting all the expenses of the civil list, providing for the mainte-

nance of an army of 20,000 men, and sending two millions and odd dollars to the mother country, had, on the 1st of January last, a balance on hand of \$644,000.

It is expected that the enlightened views of the present Spanish Government with regard to the free trade of the Island, and the suppression of various burthens which now check the progress of agriculture, will contribute towards developing still more the great natural resources of this Island.—[Cour. & Enq.]

**FROM MEXICO.**—The New Orleans True American of the 18th ult. contains the following:

The news from Mexico was brought yesterday by the brig *Bebie*, from Vera Cruz. The dates she brings from the city of Mexico, are up to the 30th May. Peace has been re-established throughout the states. Rejoicings and festivals are taking place in every town of the whole Mexican Union in honor of the late Triumph of Santa Anna. The Mexican Congress of the 23d, decreed to that successful chief, the title of "*Saviour of the Nation*." A monument is also to be erected in honor to him on the field of his victory. His next title will probably be that of Emperor, and the next gift made to him—a crown!

**FROM CANTON.**—By an arrival at Boston we have Canton papers to February 17. Later marine advices have been received via Philadelphia. The following are extracts from the papers:—

**Destruction of St. Paul's Church at Macao.**—On the night of the 26th inst., this ancient and superb edifice was totally destroyed by fire. From its conspicuous situation, standing on almost the highest ground within the walls of Macao, the grand and awful sight of the blazing pile was visible to the whole city. The fire originated in the guard house, which was a part of the building, and occupied by soldiers. The church was built by the jesuits in 1602. We hope to see a full account of this melancholy event in the next *Chronica de Macao*.

[From the *Daily Advertiser*.]

**NEWS FROM THE OTHER SIDE OF THE GLOBE.**—We have received very copious files of papers from Sydney, in New South Wales, better known by Botany Bay. We have been exceedingly amused and instructed at the contents of these journals.—One of the files, "*The Sydney Gazette*," has been established thirty-two years, and its number is 2448, in size and workmanship in no way inferior to the largest New York journals, and the talent with which it is conducted is of a high order. We have made a synopsis of the intelligence, which, although not late and important which usually graces the head of a foreign arrival, is nevertheless quite interesting.

No less than 14 vessels are now loading for London and Liverpool, in this port, and two at the Hunter. The cargoes will, of course, consist of colonial produce, and principally wool and oil.—[Ed. Syd. Gaz.]

A mechanic, of some experience, is preparing a Diorama for exhibition, in Sydney. It will embrace a view from Botany Bay to the Heads, the harbor of Port Jackson, and the principal parts of the town.

On Saturday last, seven or eight publicans were fined at the Police Office, the sum of 40s. and costs, for selling liquors in their houses on Sundays.

A meeting of the friends of Chaulker, the Champion, and Tom Crawley, took place at the Custom-House Inn, last evening, when 7000 a-side was made good. Time and place in due season.

Yesterday, being St. Catherine's day, the ropemakers in Sydney showed their respect to their patron Saint, by abstaining from work; indeed, towards the latter part of the day, some of them were in a state not quite consonant with the rules of the Temperance Society.

The Cape Packet, (Captain Hindson,) which returned from the whaling grounds on Sunday last, with a full cargo of sperm oil, may be counted one of the most, if not the most, fortunate vessels that ever left Sydney—having been absent only sixteen months. On her previous voyage, under the command of the same gentleman,

she was still more fortunate, having returned to port as full as an egg, only twelve months out; during which time she never once dropped her anchor. The Cape Packet has also had the good fortune to obtain a considerable quantity of ambergris, which is so precious at home.

Mr. John T. Wilson, with a view (we are persuaded) to advance the interests of Australia, more than from any motive of personal aggrandizement has ordered a superb steam vessel of 900 horse power, which is to ply between this and Robert Town, and she may be expected to arrive in the waters of Port Jackson within three months of this date.

We understand that a large quantity of wool will be sold this season at Mr. Lyons's wool mart, in George street. A number of the settlers, it seems, prefer disposing of their clip in the colony, to taking the risk of shipping it, and awaiting the necessary delay before they can obtain returns. In our opinion it must be a very great advantage to those with whom cash in an immediate object, to be enabled to avail themselves of the very liberal terms upon which Mr. Lyons undertakes to receive wools for sale; and we are, therefore, not surprised to learn that the supplies of that article are likely to be very abundant. Although we may expect that the wool of this colony will always continue to maintain a high character in the English market, yet we do not think that the prices of one year should be taken as the standard of another. Like the price of every other article of commerce, that of wool may be expected occasionally to fluctuate, from various causes; and we do not consider it at all unlikely that the holders of wool may, now and then obtain higher prices here than the same article will afterwards realize at home.

A small quantity of gooseberries were on sale at the Market on Tuesday, at one shilling and sixpence per quart; some cherries at 3s. per lb. were also on sale. This is the first year, we believe, that gooseberries have been exposed for sale in the Market. Upwards of three thousand bushels of maize were exported to Hobart Town last week, by the ships New York Packet and Ellen.

The Henry Porcher was about to sail for Sydney with male prisoners.

The Isabella will proceed forthwith to Norfolk Island with prisoners and stores.

The steamboat Tamar is nearly fitted up. We understand that she will make an experiment trip to George Town, and immediately afterwards be sent to Sydney for sale, where it is expected she will bring a good price. It is said that 1500 pounds a year has been offered the proprietors, by persons there, for the hire of this vessel.

George Reynolds, publican, was fined 40s. and costs, for suffering persons to sit and drink in his house on Sunday last, against the act.

Thomas Smidmore was fined 40s. and costs for the same, and several other cases of the like nature were decided.

Mary Ann Clark exhibited in the stocks two hours this morning, for being drunk and not being prepared with the needful.

We understand that the Polish gentleman lately arrived in Sydney, intends giving a series of concerts.—A meeting of the share holders have unanimously appointed Mr. W. T. Cape, as conductor of the Sydney College.

On Monday last there were thirteen wool teams between the Sydney turnpike and the fifth mile stone. Other thirteen teams were counted between that place and Liverpool. Thirteen, it is well known, is the Devil's dozen; but in this case that old gentleman had no reason to say as he said when shaving the pig—"more cry than wool."—A Mr. Benjamin Kirby was fined on Friday last, in the sum of 4s., on a charge of furiously riding through Cumberland street.

The "British Sovereign" took in her last bale of wool on Saturday, and expected to clear out for London this day.—Thirty prisoners of the crown, principally cattle stealers, were forwarded to Norfolk Island, per sch. Isabella.

THE GREAT NATION.—We apprehend the United States may now be called the "Great Nation;" and as the people of that rapidly rising republic are the descendants of Britain, speaking the same language, and governed upon principles so truly congenial to Britons, we consider the arrival of an American ship here at all times a subject of gratulation.

[From the Southern Patriot.]

# Shipwreck of the Children of Henry the 1st, of England.

MR. EDITOR,—The details of the following interesting narrative are given we believe for the first time, in an English dress to the public. It is compiled in part from an old Chronicle contemporaneous with the period of which it treats, and from an ancient record deposited in the Abby of Fontevault. History is silent as to these details, it merely relates the fact, that the Children of Henry the 1st, with a considerable body of the most illustrious persons of the realm, were lost on the passage from Normandy to England. We are therefore indebted to the industry of the Ancient Chroniclers for the relation of an event full of incidents of a most affecting and interesting character. The translation is from the pen of one of the young ladies at Madame Hery's Institution, who has upon more occasions than the present, introduced to the lovers of literature, gems of rare merit, and given exercise in this manner to powers of mind, which erst might have remained unknown, even to their fair possessor.

"The close of the year 1120, also saw the close of a long and sanguinary war, which was waged between Henry the 1st, King of England, and Louis Le Gros of France. The peace which the Belligerents then concluded, guaranteed to the English Monarch the undisputed possession of the fertile Duchy of Normandy, while on the other hand, a marriage which his son William, the heir of his throne, consummated with the beautiful Matilda of Anjou, also secured to him this rich and populous province. Thus his power was augmented, and ambition itself seemed satisfied. He saw himself master of England, and he gave law to a large portion of France. He was in the zenith of his power and glory, and he made preparation to return to Albion, surrounded with such symbols of splendor and glory, as were indeed well calculated to exhibit the march of the conqueror, and the triumphs worthy of a king.

He was accompanied in his journey from the interior to the coast of France by his family, and a numerous host of his chivalry having arrived at Barfleur in Normandy, he found several vessels, all anxious for the honor of conveying him to his paternal dominions.

When about to embark, he was accosted by a Mariner by name Thomas, who having approached the King presented him with a handsome gift, and thus addressed him: "Sire, my name is Thomas the pilot, and my father Stephen also followed the same occupation; he has served your Majesty well and long. When William the Conqueror sailed from this port, it was he who conducted the ship which bore your illustrious father across the sea; he fought under his banner; he aided him in the conflict, and under the blessing of heaven helped to achieve the victory. Permit me then, oh gracious King, to have the same post, which the good King William bestowed upon my father. I have at your royal service a brave ship, she is stout, newly built, and manned by fifty vigorous and expert seamen." The King answered him, "Friend, I have already chosen a ship and cannot change it; but in order to testify our sense of your loyalty, and of the fidelity of your family to our royal house, we will confide to you the charge of transporting to our kingdom, our two sons William and Richard, and our dearest daughter Adèle. Guard them as you would ourselves; they are dearer to us than our life! You will likewise have a number of our principal Nobility and Courtiers, and the bulk of my treasure; go now, be vigilant and be careful!"

The gallant bark, which carried the Monarch of Britain, shortly after got under weigh. She is soon out of sight, and reached Northampton in safety early next morning.

The *La Blanche Nef*, unhappily remained behind, the sailors overjoyed at their good fortune, in having so rich a freight, gave themselves up to all kinds of merriment and to expressions of extravagant joy, unfortunately a large quantity of Wine was distributed amongst them. They surround the young Princes, and testify their attachment and their pleasure, by dancing and singing. At length the Princes retire to rest, but the revelry and mirth continued on deck for some time after.

The signal for departure is given, and the ill-fated vessel is seen at last to sail. She shoots like an arrow through the water. She grows less and less distinct, and is lost at length in the receding dis-

tance. Besides the two Princes and their sister Adèle, she had likewise on board as passengers 18 ladies of the Court, the wives or daughters of the most considerable of the Nobles, and learned men, and other distinguished persons, 104 Barons and Chevaliers, the flower of the armies of Normandy and England, in all about 300 persons.

There were many, however, more provident and wise, who absolutely refused to embark in the *La Blanche Nef*—they would not consent to commit their lives to the keeping of men, who were either insensible to the calls of duty, and seemed deprived of their reason—who, said the historian, instead of attending to the adjusting of the sails and the trimming of the ship, listlessly lolled upon the benches or took possession of the coffers that incumbered the deck.

At the given signal she starts with ardor from the quay,—the *La Blanche Nef* recedes rapidly from the shore, amidst the acclamations of the people; but in the moment of entering the bay of Catte, now Gatteville, whilst the rowers, in a state of complete intoxication, employed all their strength to overtake the King, (which they made it a point of honor to do,) the left side of their ship struck against a rock with such force, that the sea immediately entered, and covered a great part thereof. The rock was called Quilleboeu, the summit of it was round, and white, and could be seen at the ebbing of the tide. A cry of distress was uttered at the same moment from all the passengers. It rose over the waters, it was heard on the shore—but no succor came; because none could divine its cause. Dismay took possession of every mind, the stoutest heart was appalled, darkness brooded over the scene, and the utmost confusion prevailed on board. Thomas the Pilot, the ill-starred author of this great disaster, sought for the Princes;—he hurries them into a boat, he is about to hasten from the scene of distress, when the young Adèle standing on the deck, perceiving them, cries out, "oh! my brothers will you abandon me," at these words Prince WILLIAM forgetful of the danger of venturing with a small launch to a vessel crowded with so many persons, held out his trembling arms towards his sister, and approached her! On the instant, the whole crew precipitate themselves into his frail bark, and it sunk with the ship—full disappeared with the bark!—but two men, one a young Knight, son of Geoffrey de le Aigle, the other a Butcher of Rouen named Berold—these kept themselves above the water by holding on to one of the masts. THOMAS the Pilot re-appeared for a moment above the water, he sees these two persons, his strength and reason appeared renewed, "Are the King's sons safe?" "They are lost with the others" was the answer he received. Oh woe! is cried the Pilot, and he sunk forever beneath the waves. It was one of those dreary, dark and cold nights of November—when the weather was calm, and the sea was serene. Scarcely a ripple disturbed the bright, the deep and awful solitude that now brooded over its bosom, the moon shone forth in cloudless splendor and revealed to the sufferers the full extent of their danger; they gave up all hopes of safety and committed themselves to the care of God! In vain they cast their eyes to the shore; in vain they lift their voices for assistance, the one is lost in immeasurable space, the other is drowned amidst the deep murmurs of a boundless ocean.—Mysterious Providence! unsearchable are thy ways! how different was the fate that awaited these unhappy men. By a strange destiny made equals in misfortune, they for some time bravely combat with their fate; companions in peril, they encourage each other by the most kind and affectionate words; united by the ties of calamity, the Butcher is now engaged in cheering on his fainting friend, and again the young Count, with the heroism becoming his blood essays the like kind offices to his humble but faithful attendant. But who can resist the power of fate. The youthful heir of Geoffrey is seen to sink, he yields to the pressure of woe: his constitution being more delicate, and his limbs less vigorous than those of the peasant Berold, become exhausted; his strength fails him, his hands are benumbed with cold, and letting go that wood which he is no longer able to grasp, he abandons himself to the sea. With a prayer to God for the salvation of his soul, and for the safety of his companion, he sinks beneath the water, one sigh from the victim, one single murmur from the passing wave, and all was over for the high hopes of a devoted mother.

The Butcher of Rouen, of all that lofty and gallant host alone escaped—to relate these details to

the Chroniclers of Fontervault, for the information of posterity. Some fishermen passing that way, clad in sheep skins, the dress at that time of their class and country, heard his moans and came to his assistance. They brought him to land, and resuscitated him with cordials and by their hospitality. On the next day, the sea cast on the coast of Bar-seur, the bodies of the shipwrecked passengers.

In the mean time Henry, ignorant of the events of that terrible night, waited impatiently for their arrival. He was alternately the subject of hope, and the victim of anxiety and expectation, the fatal news was spread by evening. But who would undertake to inform the miserable King, the wretched Father, of the frightful affliction? Who would break to him the revelation of a catastrophe, that must for ever plunge him into the dark abyss of suffering and of woe? All those around him, were partners in his grief; each had to mourn over a dear relation or a cherished friend. They employed a child, who, casting itself at the feet of the Sovereign, told him all. Ah! who now can tell the father's grief? who now will paint the parent's heart? Henry fell to the earth pierced with anguish. His gallant sons dead! his beautiful Adèle no more! He turned in disgust from glory, his hopes were blighted, the sunshine of his life was gone, and a dark night of gloom closed over him for ever. His children were snatched from him by the tyrant in the very hour of happiness, of triumph, and of honor. He shed not a tear for many days; he abandoned himself to despair; he called upon his children by name, and he would chide them for their delay. He would then awaken to his loss; tears came to his relief, and in this mood he would find an alleviation of his pain in dwelling upon their virtues and their many good qualities. He would frequently recur, also, to the brave men who perished with them, and seemed to experience a melancholy pleasure in recounting their heroic deeds, and in the relation of acts of valor which made his Knights the flower of Chivalry, and illustrious before the armies of Europe. From that terrible day, continues the ancient MS., Henry the First of England, one of the greatest monarchs in Christendom, was never seen to smile.

Prince William was 16 years of age when he married Matilda, heiress of Anjou. She was then about 14, lovely and endowed with a mind, cultivated with care by the good monks, who followed a life of piety and letters under the protection of her father. She was in the vessel with the king, her father-in-law, and thus escaped the misfortunes of her husband. They had been married but a few days.

The young Princess was pierced with grief that was inconsolable when she heard of her husband's death. She mourned over his fate and refused to be comforted; they were so lovely, so united and so young. Alas! she was indeed an object of compassion and tender pity. In a very short time after these events took place, Matilda returned to her father, but the seductions of a Court had no charms for a wounded spirit, and finding that the brilliant circles of the gay and the refined, only increased the bitterness of her regrets, he consented at length to her entering into the Abbey of Fontervault, where she spent the rest of her days, if not happy, at least tranquil and resigned; her time was employed in acts of usefulness, of virtue, and in prayer. After due season she took the veil, and became the second Abbess of that celebrated institution, and by the gentle charities which she diffused around her, and the odour arising from a life of sanctity and good example, by innumerable acts of benevolence and humanity, and by the performance of other good works, she was so esteemed, so revered, and so beloved, that to the poor of her neighborhood she became indeed a second mother, and was regarded in the light of a Guardian Angel.

"The Countess de Provence to her Husband.—Chanson  
Vos ge m'assemblés del corals anachors.

I fain would think thou hast a heart,  
Although it thine its thoughts conceal,  
Which well could bear a tender part  
In all the fondness that I feel!

Alas! that thou wouldst let me know,  
And end at once my doubts and woe!  
It might be well that once I seemed  
To check the love I prized so dear,  
But now my coldness is redeem'd,  
And what is left for thee to fear?  
Thou dost to both a cruel wrong,  
Shouldst dread in mutual love be known?  
Why let my heart lament so long,  
And still to claim what is thine own?"

La Gantille Marguerite, the unhappy wife Louis the Eleventh, when dying broken-hearted in consequence of the cruel treatment of her husband, on being comforted by one of her attendants who spoke of hope and life, exclaimed, as she turned away in despair, 'Fi de la vie—ne m' parlez plus,'—and expired.

The following lines are in illustration of the declaration of that beautiful and wretched queen:

Oh! speak to me of life no more!  
Its lurid star will soon decline,  
Soon will its miseries be o'er,  
Its pleasures never have been mine.  
Out upon life! oh, if to live,  
As I so long have done,  
Is all this niggard world can give,  
'Tis well my said is run.  
Why should I shrink, or why delay?  
The future cannot show  
Ought that can charm my soul to stay,  
Or bid me sigh to go.  
Out upon life! it might have given  
A lot from sorrow free—  
It might have shone with hues of heaven,  
But they were not for me!  
This heart was fond, this heart was true,  
But wither'd, torn, oppress'd,  
It could not now its pulse renew,  
Or warm this tortured breast.  
What has it now with life to do,  
So changed from what it was of yore?  
The world is fading from my view,  
Oh! speak to me of life no more!

#### PARTNER WANTED.

Wanted, a partner in an extensive Printing Establishment. No one need apply who is not a thorough bred printer, competent to superintend and direct office in which upwards of 30 persons are employed and able to furnish \$3000 cash capital. The best references will be given and required. Letters, with real name, may be addressed to P. P. P., Post Office New-York, postage paid, and they will be promptly attended to. May-17

#### TO TUNNEL MINERS, DRILLERS, &c.

Wanted, immediately, 40 Tunnel Miners, (Cornish Men will be preferred,) 80 Drillers, 50 Laborers, and 2 experienced Mine Blacksmiths, on the New York and Harlem Railroad, about five miles from the City. Liberal wages will be given, and cash payments made every fortnight. Apply at Mr. FOWLER'S, St. John's Hall, Front Street, New-York.

JOHN RUTTER, Contractor.

37 The Albany Argus, Philadelphia U. S. Gazette and Pennsylvania, will please copy this, and send their bills to the Railroad Company, 14 Wall street, New-York. 22-

#### RAILROAD IRON.

300 Tons Railroad Iron, 3 inch by 1, with Spikes and Splicing Plates to match, for sale by  
WM. G. BULL & CO.  
35-37 74 Wall-st.

#### RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Engine Air Furnace and Machine Shop, will make to order cast wheels, chairs and knees, and every other description of castings required for railroads. R-17 Feb 14

#### PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

13 Railroad Spikes of every description required made at the Albany Spike Factory.  
Spikes made at the above Factory are recommended to be public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head so as not to admit water.

Orders may be addressed to Messrs. SEASTUS CORNING & CO., Albany, or to THOMASTUNER, at the Factory, Troy, N. Y. sept. 13-17

#### PATENT RAILROAD, SHIP AND BOAT SPIKES.

13 The Troy Iron and Nail Factory keeps constantly for sale every extensive assortment of Wrought Spikes and Nails, from 8 to 10 inches, manufactured by the subscriber's Patent Machinery, which after five years successful operation and now almost universal use in the United States (as well as England, where the subscriber obtained a Patent,) are found superior to any ever offered in market.

Railroad Companies may be supplied with Spikes having countersink heads suitable to the holes in iron rails, to any amount and on short notice. Almost all the Railroads now in progress in the United States are fastened with Spikes made at the above named factory—for which purpose they are found invaluable, as their admission is more than double any common spikes made by the hammer.

13 All orders directed to the Agent, Troy, N. Y., will be punctually attended to. HENRY BURDEN, Agent.

Troy, N. Y. July, 1831.

13 Spikes are kept for sale, at factory prices, by I. & J. Townsend, Albany, and the principal Iron Merchants in Albany and Troy; J. I. Brower, 223 Waterstreet, New-York; A. M. Jones, Philadelphia; T. Jaaviers, Baltimore; Degrad & Smith, Boston.

13 Railroad Companies would do well to forward their orders as early as practicable, as the subscriber is desirous of extending the manufacturing so as to keep pace with the daily increasing demand for his Spikes.

15th Jan

H. BURDEN.

#### STEPHENSON.

superior style of Passenger Cars for Railroads,

1 Elizabeth street, near Blooming street, New-York.

LOAD COMPANIES would do well to have Cars; a specimen of which may be seen of the New-York and Harlem Railroad Co. J361f

#### DCAR WHEELS AND BOXES, OTHER RAILROAD CASTINGS.

AXLES furnished and fitted to wheels the Jefferson Cotton and Wool Machine Foundry, Paterson, N. J. All orders addressed to subscribers at Paterson, or 60 Wall st., will be promptly attended to. SPRINGS.

13 Tires turned complete.

GERB. KETCHUM & GROSVENOR

#### RAILWAY IRON.

1 inch by 1 inch, Flat Bars in lengths of 14 to 15 feet, counter sunk do. do. holes, endcut steel angle do. do. of 45 degrees, with splicing plates and nails to be specified. 13 Railroad of 36 lbs. per yard, with the keys and pins. 13 Rims of 30, 33, and 36 inches diameter Railway Cars, and of 60 inches diameter wheels.

13, 24, 3, 34, 34, and 34 inches diameter for Locomotives of patent iron. 13 All sold free of duty, to State Government, incorporated Governments, and the Drawback payment. A. & G. RALSTON.

13 South Front street, Philadelphia. samples of all the different kinds of Rails, Wedges, Spikes, and Splicing Plates, in use in the Great Britain, will be exhibited to examine them. 13th Dec 1831

#### BYORS' INSTRUMENTS.

13 of various sizes and of superior quality.

13 instruments, large and small sizes, with high vena with glasses made by Traugott, to large assortment of Engineering Instruments and sold by  
J. & G. W. BLUNT, 164 Water street, corner of Maiden lane.

#### ING AND ENGINEERING INSTRUMENTS.

13 writer manufactures all kinds of Instruments, warranted equal, if not superior, construction and workmanship to any instrument in the United States; several of which are among which are an improved Telescope attached, by which angles can be run without the use of the needle, with a Railroad Goniometer, with two Telescopes, Leveling Instrument, with a Goniometer adapted to Railroad purposes.

WM. J. YOUNG.  
Mathematical Instrument Maker,  
No. 9 Dock st., Philadelphia.

13 recommendations are respectfully submitted, Surveyors, and others interested. Baltimore, 1833.

13 Inquiries respecting the Instruments mentioned, now in use on the Baltimore and Ohio Railroad, furnish the following information: whole number of Levels now in possession of construction of them make is seven of the "Improved Compass" is eight of the number in the service of the Railroad Department.

13 Compasses are in good repair. They had but little repairs, except from accidents of the kind are liable. 13 hat they possess for the levels and compasses preferred by my assistants generally, to the, and the Improved Compass is superior of Goniometer that we have yet had on this Road.

13 more recently improved with a vena in place of the vena sights, leaves the only thing to desire in the formation of the Compass. It is indeed the most complete lateral angles of any simple and cheap I have yet seen, and I cannot but believe to all others now in use for laying of, when known, I think it will be as highly common surveying.

13 F. STABLEY, Sup't of Construction of Baltimore and Ohio Railroad.

13 Philadelphia, February, 1833. 13 last two years made constant use of a Patent Improved Compass, I can easily be much superior to any other instrument in use, and as such most cheerfully recommend and Surveyors.

13 E. H. OILL, Civil Engineer. 13 Germantown, February, 1833. 13 I have used Instruments made by Mr. Philadelphia, in which he has combined a Theodolite with the common Level. 13 Instruments admirably calculated for use, and can recommend them to the persons as preferable to any others for that

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, JULY 18, 1835.

**TO BOSTON BY DAYLIGHT.**—We understand that the Stonington and Providence Railroad is progressing rapidly. The route is a very level one, and one fourth of it, and that the most difficult, is already graded.

It is expected that the road will be ready for use next season, when all who travel for pleasure will be enabled to leave New-York in the morning in the Stonington steamboat, avoiding all the horrors of Point Judith and open sea navigation, and arrive at Boston in good time, by the Stonington and Providence and Boston and Providence Railroads, the same evening.

Those who travel for business, may, by the same route, leave New-York at night, and be in Boston the next morning; transact business during business hours, and be in New-York to breakfast the next morning; being absent from New-York but one day, and spending that day in Boston: thereby bringing us as near to Boston, in a business point of view, as we now are to Albany.

Another most important advantage which this route has is, that it is always open, as the Stonington harbor never freezes, and was not, as we are informed, even for an hour, the last, the coldest of all winters; and the serious interruption to the intercourse which occurs in winter cannot happen after this road is finished.

The saving of time, the pleasantness of the steamboat passage (it being all within the Sound), and the certainty of uninterrupted communication, will be of immense importance to New-York, Boston, and Providence, and will doubtless greatly increase the already immense travel between them.

[From the Baltimore American.]

**CANAL FROM COLUMBIA TO THE CHESAPEAKE.**—The organization of the Susquehanna Canal Company took place on the 8th inst. at Columbia, in conformity with the requisitions of the Act of Incorporation passed at the last session of the Pennsylvania Legislature. A President, twelve Managers and a Treasurer, were chosen by the stockholders present, who represented for themselves and their friends about nine-tenths of the whole stock. Shortly after the election was terminated, the Board elect entered upon the duties of their appointment, and on that and the following day transacted all the business which could be disposed of at the first meeting. In the selection of Chief Engineer the Board were unanimously in favor of Edward F. Gay, Esq. a gentleman enjoying a very high reputation for professional talent and experience, and who has for some years past occupied a responsible station as Engineer on the Pennsylvania State works. Among the measures adopted by the Board was one directing the necessary steps for the opening of stock transfer books in Baltimore, Philadelphia, New York and Boston. We are truly gratified to be able to add that, in reference to the question of the speedy completion of the canal, there is but one opinion entertained by its friends;—the sentiment is as strong as it is unanimous, that the work should be finished at the earliest possible period. The interests of the people of Pennsylvania and those on the tide water are one and the same in regard to this important question, and their mutual co-operation will be faithfully and energetically directed to the successful attainment of their common object. We cannot conclude this paragraph without congratulating our fellow citizens on the auspicious aspect which the affairs of the Company present at the commencement of an undertaking whose accomplishment identifies the interests and prosperity of our city closely and forever with those of the flourishing State of Pennsylvania.

**A LITTLE TOO FAST.**—Under the head of "Progress of Steam Travelling in the United States," we find the following in the London Literary Gazette, of 23d May. It evidently refers to Burden's boat, the catastrophe of which appears to have been unknown.

**PROGRESS OF STEAM TRAVELLING IN THE UNITED STATES.**—In addition to the numerous steam-vessels navigating the Hudson, between New York and Albany, one is now making the trip there and back daily, a distance of 290 miles, in thirteen hours. This vessel is 300 feet in length by 40 broad, formed of two enormously long canoes, sharp pointed at each end, and connected together by a platform, leaving a certain space between them, in which the machinery acts. Upon the platform are built the cabins and other necessary erections. This steamer is for the accommodation of passengers only.

**PNEUMATIC RAILWAYS.**—We have been favored by a friend in London with the following communication on a new, called *Pneumatic*, system of railways. It must, we think, be considered as one of the visions of the day; yet that is no affair of ours, as we aim to give our readers an account of whatever pertains to the subject of internal improvements, be it ever so visionary—if we imagine that any new idea may be gained from it which will, or may, benefit the great cause; and it is for the purpose of eliciting discussion that we lay this communication, and the opinion of Dr. Lardner and Faraday, (published in No. 25 of the Railroad Journal,) before our readers.

That the adoption of railroads as the means of inland transit has become a subject of deep interest to the community, and that their vast advantages are duly appreciated, is evinced not only by the ready support which is given by the public to the spirited efforts now making for their extensive application, but also by the sanction which has been accorded them by the Legislature. Indeed, at the present moment, an almost incalculable amount of capital is actually pledged to the institution of a general system of railway throughout the kingdom.

But notwithstanding the admitted advantages of railroads, as at present constructed, worked as they are by the locomotive steam engine, over the old system of transit, that splendid experiment, the Liverpool and Manchester line itself,—to the projectors and managers of which the nation is so greatly indebted for the stimulus it has given to improvements in inland transit and consequent benefit to commerce, the extent of which, indeed, are not yet fully developed,—has at the same time disclosed the inefficiency of the construction by its utter inability to withstand the violent action and tremendous concussions of the ponderous engine, which is also destroyed by its own

The first figure represents a Pneumatic Railway in operation, with trains on a double track, approaching each other, one having just passed a stationary engine. This was designed to represent two trains passing a station, but by mistake the station was mislabeled by the engraver.

The second figure represents a sectional view of the railway cylinder, showing the internal arrangement.

force, and the imperfections of the locomotive system by the incompetency of the engine to work with advantage except upon a level. Hence the wear and tear of the railways in that line has amounted to not less than £500 per mile per annum, whilst the locomotive engines, of which not less than thirty\* are employed upon the road, besides nearly half that number more which come upon it from branch lines, are worked and maintained at the enormous cost of more than £2,000 per annum each.

The immense expenditure of capital required in the formation and construction of the common railroad, owing in a great measure to the necessity of obtaining a nearly perfect level, and the great cost of maintaining and working the ways when they are formed, will necessarily induce the public readily to adopt any improvement which shall have the effect of increasing the stability of the railway at a diminished cost; and especially if it combine with it greater security, efficiency, and economy in the working.

The invention, which is the basis of the improvement now submitted to the public, consists in the means of applying the elastic and forcing power of the atmosphere, obtained by rarefaction within a hollow cylinder of from thirty to forty inches in diameter, to carriages and cars running upon rails on its outer surface; the action being produced and transferred by means of pneumatic machinery worked by sufficiently powerful fixed or local steam engines.

Steam power, used as a first mover, admits of no application so economical as that by means of fixed engines;† and thus motive power will be obtained at one quarter the expense of that yielded by the locomotive engine. The fixed engine gives also the advantage which the locomotive does not possess, that the intensity of its force can be greatly varied to suit the exigencies of the road, and thus it may be rendered available according to the nature of the slope, or steepness of

the acclivity to be overcome, the weight to be moved, and the degree of rapidity required. Unlike that of the locomotive engine, the power of the fixed engine is, by the improved system, communicated with no indirect expenditure to the load or train of carriages; whilst the power of the locomotive is first applied to bear along its own ponderous bulk, which is of about ten tons weight, or fully one fourth of its usual load, and, as before remarked, it destroys both railway and engine by its violent action and concussive force.

The power of surmounting acclivities renders the most direct lines of communication available, and thus shortens the distances between places, and avoids the necessity of circuitous routes in search of levels. Moreover, the improved system of railway permits of roads being laid through a marsh as well as over a common or down, and with no greater expense, thus affording the means, in many cases, of avoiding the annoyance, inconvenience, and expense, of running roads through parks, and over arable lands. It may be remarked, too, that the great expense involved in the formation and construction of a railroad upon the common system, is totally sunk in cutting down or in tunnelling through hills, and in building across or embanking over valleys; whereas the main expense involved in the formation of a road on the improved system, is in common iron castings, which being almost indestructible, and possessing an intrinsic value, little or no loss can accrue upon them.

Not only does the improved system present a firmer construction of the railway, and a highly economical application of power, but it affords also greater protection to life and property, in the security of the carriages and cars for the conveyance of passengers and goods, since these are so placed upon the rails, and so connected with the railway itself, that they cannot by any possibility be thrown off or overturned. In consequence of this advantage, whatever objection may exist in the public mind to travelling upon railways, because of the danger connected with the common system, will be entirely removed, and a great improvement may be confidently calculated upon in the important item of passenger traffic.

When it is considered that, by the improved system, a line of road may be formed and constructed for, at the most, two-thirds, and in some cases for one half, the expense involved by the common system, and that such a railway can be maintained and worked with far greater speed, and infinitely greater safety, for three-fourths less than the common system costs, and that therefore passengers and goods may be conveyed at one half the price which the common system demands, and then yield a far greater profit, competition with the Association will be wholly out of the question.

As any degree of speed can be obtained by the improved system, with the most perfect safety, and without the disadvantage, not to say danger, arising from great velocity on the common method, a single line, on the new system, can be made, by the reciprocating plan proposed, to effect as much transit as can be effected by the use of a double line on the former, while the cost will thereby be lessened nearly one half. Hence, communications that may not warrant the expense of a double line of railway, may be advantageously occupied with a single line; numberless lines are in this manner open to the application of the new system, which the common method will not permit of being attempted.

As the invention affords the means of applying the power to the common railway, the proprietors of such must soon be found anxious to avail themselves of its advantages; and thus all the railroads in the country may soon become tributary to the Association, while the interests of the various concerns themselves will be materially improved by the adoption of the improvement.

As many millions are actually invested in this country in canals, and that species of property may be much deteriorated by the general application of railways, unless this improvement which affords them the means of increased speed is adopted by the respective canal proprietaries, the Association may fairly calculate upon rendering all these interests likewise tributary, in exchange for the advantages to be derived from the licence to apply their improved system.

In addition to affording the means of transit upon railways, whether upon the improved or with the common system, the power may in like manner be applied to effect rapid transit, with great economy, upon canals.

The practicability of the improvement, and the efficiency of the application, are proved by experimental operation, and confirmed by the opinion of the most eminent scientific men in the kingdom.

\* This number, at least, is possessed by the Company, though not more than half of them are at any time in working condition; the other half are always in hospital to be repaired.

† A fixed steam engine will last twenty-five years, and the depreciation will not be more than 11 per cent. per annum.

The following communication in relation to Pneumatic Railways has been several days in hand. The writer who had only read the article in No. 25 of the Journal, will now have seen more in relation to it in this number.

[For the American Railroad Journal.]

MR. MINOR.—When will common sense be the order of the day? When shall we again be able to look upon a new scheme as one likely to prove practically useful? This is truly the age of invention and originality; but unfortunately we are still wandering in the green fields of imagination. The *Age of Reason* appears to be yet far distant. But who but a man of *original* mind could have invented either of the three plans which have been lately presented to us through the papers, as marvellously practicable, and calculated to produce a new era in the *moving power* of the world. I refer first to the invention, *by somebody*, (my bump of individuality is too small to enable me to remember all the names connected with these things,) of laying rails on the tow-path of canals, thereby incurring the expense of a road over and above the common expense of a canal, for the purpose of substituting a power upon it which can never be used.

Next comes the invention of Mr. Heron, called a "Water Power Railway:" a scheme which, besides costing at least three times as much as Mr. Heron's estimate for it, is as wanting in practical application as the former.

Lastly comes an invention from over the water, fathered also by an American, and backed by the learning of the Rev. Dion. Lardner, Mr. Faraday, &c. This is the "Pneumatic Railway," whereon we are to be impelled by the "thin air."

This is something philosophical! it is worth reasoning about! It appears that after the railroad proper is finished, which of course must be as good, if not better, than those made at present, and consequently will cost as much, then the moving power is to be added.

According to the plan of the patentee, this is to consist of a tunnel provided with a piston, to which the cars are to be attached. The tunnel being exhausted of air by means of air pumps, worked by stationary steam engines, the piston, and consequently the cars attached to it, will be impelled by the pressure of the outward air. Suppose, with the patentee, that six stationary engines be placed between Liverpool and Manchester, they will be five miles apart. Now, when but one train of cars can be put in motion at the same time between the engines, and after a train has passed, the five miles of tunnel will have to be re-exhausted before another train can take its place, it appears to me that either more than superhuman power must be exercised in the management of the road, or that there will be very great delay in passing over it. But admitting all this to be arranged, and supposing also that there will be no insurmountable difficulty in laying down and

securing the tunnel in so *exact* a manner as it must be, in order to be effective, let us look a little to the *expense* of the project.

I have no information relative to the material which the patentee intends using in the construction of his tunnel, but take it for granted that it must be of cast iron. The quantity of metal contained in a cast iron tunnel 40 inches diameter, in clear, and one inch thick, will be about 401.67 pounds for every lineal foot, or about 946.7 tons per mile.

The whole cost of the tunnel and its appendages may be estimated as follows:

Naked tunnel per mile, 946.7 tons of cast iron, at \$80,	\$37,868 00
Suppose the above to be cast in lengths of 5 feet; then, allowing the usual quantity of metal at the joints, this item will amount per mile,	
to 140 tons, at \$40,	4,160 00
Chairs, 159 tons, at \$40,	6,360 00
Stone sleepers,	2,500 00
Bolts, spikes, &c.,	500 00
Workmanship,	5,000 00

Total cost for a single track, \$56,388 00  
Do. double track, \$112,776 00

To this is to be added the cost of the railroad proper, and the stationary power to work the tunnels—say for the whole \$160,000 per mile. A truly economical affair!!

Now, my dear sir, having treated the scheme of others somewhat familiarly, let me exhibit to you a plan of my own, towards which I invite the investigation of scientific men.

I propose making the whole railroad into a tunnel, either by boring the hills, or building upon the surface. Into this a piston must be fitted, to which the cars are to be attached. The *modus operandi* will of course be the same as for Mr. Perkins' tunnel. The difference between Mr. Perkins' and my own scheme is this: Mr. P. first grades his road, and then places his tunnel upon it. It is thereby insecure in the first instance, and liable to derangement ever afterwards; but by my plan, the tunnel and road are one and the same thing. In making the road, the tunnel is made also. Then, as to power; instead of a piston of 9 feet surface, we have one of 144 feet. The stationary engines I propose having outside of the tunnel over the air-shafts.

The expense of a railway of this kind will be about \$175,000 per mile, or a little more than one upon Mr. Perkins' plan.

ENGINEER.

June 29, 1835.

[From the London Mechanics' Magazine.]

SAFETY APPENDAGE TO RAILWAY-CARRIAGES.—Sir: Of the various accidents which occasionally happen on railways, those caused by waggons being thrown off the rails by sticks or stones laying across or on the rails, are the most numerous. Being on the Stockton and Darlington railway a few weeks ago, I saw an instance of the kind, but fortunately no harm ensued.

A train of waggons, heavily laden, was proceeding at the rate of about sixteen miles an hour, when one of the wheels of the foremost of the train came in contact with a piece of coal, which happened to be laying on the plate, and such was the force of meeting, that the waggon leapt two or three inches high. Fortunately, however, it alighted in its proper position on the rails; for, had it gone off the way, such was the velocity of the other waggons, that they must have been inevitably dashed to pieces, and the person attending them either killed or severely wounded. As it was, no further damage was experienced than a slight concussion, which was felt to the end of the train; owing to the first waggon losing time by leaping, and the rest overtaking and striking against it. Being an eye-witness of this *almost* catastrophe, it naturally made me try to devise some plan to remedy the possibility of accident on that head, and the following was the result of my cogitations. On each side of the first waggon of the train, I would have a kind of shovel fixed, so hung as just to clear the rail, that it may cause no unnecessary friction. Now, were a stone, stick, or any thing else, laying on or across the way, it would be an utter impossibility for the waggon to run over it, as it would not come in contact with the wheel. The shovel would either throw it off the rails or push it forward. Even if a man should fall across the road, as sometimes happens, instead of having his legs cut off, he would be thrown on one side, and be but little if at all hurt. This shovel might be hung by an adjusting chain, and in cases of severe frost, or a slight fall of snow over-night, might be let down upon the rail, when it would prepare it for the progress of the vehicle.

I am, Sir, yours respectfully,

WM. PEARSON.

Bishop-Auckland, Nov. 4, 1834.

[Since the date of the preceding communication from Mr. Pearson, we have received another letter from him, in which he says: "About two days after I had sent you my proposed Safety Appendage for Railway-carriages, an accident happened on the Stockton and Darlington railway, which I feel assured could not have happened had the plan there proposed been in use. The misfortune alluded to befel as follows: an engine, with a train of waggons, proceeding down the way at a rapid rate, came in contact with an old brake, which was laying across the rails, and by the concussion the engine was thrown off the road—the engine-man (James Cleasby) was killed, his brains being dashed out against the water-tank, and much damage was done besides. The proprietors of the railway were so convinced that the brake had been designedly laid across the way, that they offered a reward of twenty pounds on the conviction of the miscreant who did it; but, unhappily for the cause of justice and humanity, the 'foul deed' has not yet been brought to light. On hearing how the accident occurred, I felt convinced that the appendage I have proposed would have prevented it. It must either have pushed the brake before the engine, till the engineer became aware of the impediment, or have eventually shoved it off the road! The wheel could not possibly have come in contact with it, and therefore the engine could not have been thrown off the road!" Two plans for the prevention of such accidents, very similar to that of Mr. Pearson, were proposed by Sir George Cayley, Bart., and Mr. Suddington.—Ed. London Mechanics' Magazine.]

The following notice, from the U. States (Phila.) Gazette, of Mr. Young's apparatus for preventing fire from locomotive engines, is well worthy of attention. It is very important that measures should be adopted on all railroads to prevent accidents by fire. We earnestly recommend Mr. Young's improvement to the attention of those interested in railroads—"an ounce of prevention, &c." Every person understands this old adage.

**YOUNG'S PATENT SPARK CATCHER FOR LOCOMOTIVE ENGINES.**

Mr. Editor: At a time like the present, when the extension of railroads throughout our country is becoming so general, and the employment of locomotive engines has become a matter of course, I deem it important that all persons connected with the management of railroads should be made acquainted with the fact, that a complete remedy exists for the greatest nuisance to which this mode of travelling is liable, viz: the emission of sparks from the engine. That remedy is to be found in the contrivance with the name of which this article is headed, and the patentee is prepared to dispose of the right of using it, either at a reasonable rate for each engine, or at a gross sum, to be paid for the privilege by each company that may be desirous of availing itself of his invention.

It is now upwards of two years since the Spark Catcher of Mr. Young\* has been in use on the New-Castle and Frenchtown railroad, since which period no instance has occurred on that road of a single garment having had a hole burnt in it by a spark from a locomotive engine. Of the tens of thousands of persons who have travelled the New-Castle road during the period named, not one can be found to gainsay the above statement.

Is there a single person, who has travelled on any other road in the United States, on which locomotives are used, with wood for fuel, that has not been annoyed, and either had his flesh or clothing burnt during his journey, by the means I have mentioned? I do not believe there is one to be found.

Is the Camden and Amboy road free from the intolerable and dangerous annoyance? No!—Baggage cars have been burnt, passenger cars have been on fire, and ladies almost denuded.

Is the great thoroughfare of Pennsylvania, the Columbia railroad, free from it? No! Barns, wood, crops of grain, and fences, have fallen beneath the flames in turn.

Are the Philadelphia and Trenton, the Philadelphia and Germantown,—in a word, are any of our railroads in the whole country, from Maine to Louisiana, provided against the inconvenience and danger of which I am speaking? No! not one.

We have arrived then at this point; the greatest drawback to the pleasure and safety of travelling on railroads with locomotive engines, is fire emitted from the chimnies of the engines, and against this a perfect preventive exists, the right to use which may be obtained by any Company that see proper to purchase it, at a reasonable price. One Company only in the United States has availed itself of it. The question for the public to decide is, whether they will suffer this sort of carelessness or false economy to prevail in Railroad Boards any longer, and

\* Mr. Young is the Engineer of locomotive power on the New-Castle and Frenchtown road, and resides at New-Castle.

allow their own property and lives, and those of their wives and children, to be jeopardized, or whether they will resolve with one accord to prosecute in all cases of damage the Company that undertakes to convey them safely without taking the proper precautions to do so.

The writer of this article is as ardently attached to the-railroad system as any man in the country. He has long looked on the monstrous abuse, he is now noticing, in silence, but a solemn sense of duty, quickened by a recent signal illustration of the danger to which life is subjected by neglect in guarding against the particular evil of fire, has at length urged him to break his silence.

And I hope that this brief notice may induce a general attention to the subject, which is one, in my humble judgment, of paramount importance both to the corporations alluded to, and the public.

One word more. The assertion is distinctly made, and all contradiction of it denied, that Young's Spark Catchers are a perfect preventive to the emission of sparks from the chimnies of locomotive engines when in use. I believe it might be asserted with equal safety, that no other contrivance has been found to answer at all.

June 16th.

L.

[From the Farmers' Register.]

*On Price—the Causes and Effects of the Fluctuations considered, and the Principles maintained applied to the Present Rage for Speculation.* By THOMAS R. DEW, Professor of Political Economy, &c., in the College of William and Mary.

[The following communication was intended by its author to appear anonymously—and it may be observed that its form still accords with that intention—though we have obtained permission to give the author's name. This mark of its origin was desirable, not only for reasons which are sufficiently obvious, but also because the facts treated of are in some degree effects of the causes considered by the same writer in his "Essay on Usury," in Vol. II. of Farmers' Register—and the reasoning of the two communications have a corresponding connexion.]

The exhibition of the principles which constitute price in general, and the investigation of the causes of unfounded and ruinous fluctuations, may be serviceable to the agricultural community at this time, when there is every indication of the approach of one of those fits of national delusion or madness, such as occurred in the time of non-specie paying banks in this country, and such as every commercial country is sometimes liable to suffer from.

In addition to the close connexion of this and many other subjects of political economy with agricultural interests, we find ground for especial approbation of Professor Dew's manner of inculcating his doctrines, by showing their bearing on current events, and offering tests of their truth, in accessible and striking practical proofs. Without resort to some such mode of attracting attention to what is generally (though incorrectly) deemed a dry and repulsive study, the abstract truths of political economy will continue unknown to governments and to nations, long after having been established and undoubted in the opinions of reading men. Thus Adam Smith's exposure of the restrictive (or 'commercial') system of Europe had delighted and convinced the learned and literary community for half a century before it had any effect on the action

of the British government, and his admirable work had long been a text book in the colleges in the United States, while our legislators still continued to act in defiance of its truths, on questions of national policy, and in accordance with the notions on trade of the past ages of darkness and ignorance.

Having thus expressed general approbation of the author's views, it is proper to mention an exception—which expression of dissent would otherwise be uncalled for, and unnecessary. It relates to the effects anticipated to Virginia from the present high price of slaves. That such consequences, whether immediate or remote, will follow, we have not been convinced by the author's argument.—ED. FARM. REG.]

But a little while since, as we all but too well remember, the country was plunged into the utmost distress from want of money, lowness of prices, and failure of credit every where; now we seem to be fast rushing into the opposite extreme—money is becoming very plentiful, prices have almost doubled, and commercial credit seems every where re-established. A speculating mania has been generated in our large commercial cities, and seems rapidly spreading itself through our country. If then this be a season of prosperity, it is one of hazard likewise. Now is the time for the exertion of that prudent foresight and calm deliberation, which alone can carry the man of wealth safely through those great and sometimes rapid fluctuations of prices, always attendant on the rage for speculation. I propose briefly in this communication to point out the operation of those causes which are calculated to make money plentiful or scarce, (as it is commonly termed,) and to show their operation on prices at this moment. This investigation cannot, I think, fail to be interesting at this time, and I hope will call forth the speculations of others much more competent to do justice to the subject than myself.

*Circulating Medium.*—The first subject, undoubtedly, to which we must turn our attention in an investigation of this kind, is to the currency. What is the currency? What are the items which compose it? Every thing which passes from hand to hand, and will perform the function of money, must be regarded as currency. First then come the gold and silver coins, and bank paper; these of course form a part of the circulating medium, but not the only, or even the greatest or most important portion. Bonds, promissory notes, scrip notes, bills of exchange, stocks of every description, form likewise a portion of the circulating medium. All of these pass from hand to hand, and represent value, and therefore perform the functions of money. For example, I buy a tract of land, for which I give \$10,000, and pay for it by passing to the seller ten bonds of a thousand dollars each. Now this exchange is effected without a single dollar of real money, merely by the agency of credit: in the same way I might have paid for it in stocks, or by giving bills of exchange, &c. But although these are to be looked on as circulating medium, it is evident that equal quantities of them will not perform as many exchanges as money; for the value of money is well ascertained—it bears no interest whilst in our hands, and therefore it circulates rapidly and effects many exchanges: whereas the value of bonds, promissory notes, bills of exchange, stocks, &c., have a value more indefinite; and most of this species of paper, too, bears an interest while in our hands. Its circulation is there-

fore comparatively sluggish, in consequence, first, of the difficulty of fixing its value; and second, because we make a profit on it whilst lying in our hands, and therefore are in no hurry, generally, to get rid of it. But although this portion of the circulating medium be greatly inferior to money in the performance of the functions of circulation, yet it much more than makes up for this deficiency, by the vast amount of it which is in circulation. In England, for example, it has been computed that the bills of exchange alone in circulation are ten times more in amount than the whole money in the country; while the latter is estimated at £40,000,000, the former reaches the enormous aggregate of £400,000,000. In our country, the Bank of the United States alone does a business in exchange amounting in the year to more than \$250,000,000; while its own paper in circulation has never reached one capital, or \$35,000,000. Now, the bonds or promissory notes of individuals may be looked on as rising, in amount, infinitely beyond the aggregate of the bills of exchange and money together. Comparing then all the items of the circulating medium, exclusive of money, with the money, we shall be astonished to see how insignificant in quantity the latter is, when compared with the former. The fact is, money performs but few of the exchanges of society, by actual passage from hand to hand. "In England," says Mr. Wade, "by the use of bills of exchange, bills of lading, checks, scrip notes, clearing houses, and a variety of other contrivances, aided by a vast fabric of credit taken and given in open account, money (in its common acceptation) hardly ever enters into mercantile affairs; it is the substance really meant and shadowed forth; but it rarely, as one may say, bodily passes from hand to hand." In our own country, every one, too, must have observed how rarely the exchange of large masses of property are effected by the intervention of money. In the great majority of cases, the property is paid for by the passage of bonds, bills of exchange, stocks, &c. and but a small portion by actual money. Hence what are called cash sales, if too frequent all of a sudden, in a particular neighborhood, even in times of great prosperity, will cause the property to be sold at a sacrifice, because of the great difficulty of commanding the actual money to make the purchase.

**Effect of Rapidity of Circulation.**—Having thus explained my notion of the components of the circulating medium, and shown that money is vastly inferior in amount to all the other items combined, let us now look a moment to the effect produced on the circulating medium by a rapid or sluggish circulation. And it is very evident, that while the quantity of the currency remains the same, its apparent amount and real efficacy may be either increased or diminished, merely by an increase or diminution of the rapidity of circulation. For example, \$10 passing through ten hands, in the course of the day, will accumulate as much property as \$100 passing only once from hand to hand. Now, supposing the whole circulating medium to remain stationary in amount, but that the rapidity of its circulation is suddenly doubled throughout the whole country, then its *apparent* amount and its *real* efficacy would be doubled likewise. With the help of these incontrovertible principles, let us now proceed to examine into the effect of the late money pressure in the United States; 1st, On the rapidity of the circulation—and 2ndly, On the amount of the circulating medium.

**1st. Effect on Circulation.**—I shall not pretend to enter into an investigation of the causes which produced the late pressure in the money market. The nation has already been fully and completely enlightened upon this subject, by men whose minds can compare with any which the world can furnish. Moreover, it would require me to enter more fully into the field of politics, than would be agreeable to myself, or suitable to an agricultural journal. Suffice it to say that the pressure did every where take place; that a general difficulty of procuring money existed throughout the country; that prices, for a season, fell every where; and that confidence and credit for a short time, in the great commercial towns, were almost entirely destroyed. First let us see the effects of all this on the exchanges in society, and then on the rapidity of circulation in the currency.

During a pressure of the kind just spoken of, the loss of confidence and fall of prices force a great deal of real and other property in the market, to be sold for payment of debts, which ordinarily remains stationary in the hands of its owners. Lands, houses, negroes, stocks of goods, &c., are thus forced to change hands, and of course increase the exchanges. Perhaps the sinking of prices generally may have a tendency to diminish the sales of the annual products of the soil, such as corn, wheat, tobacco, and sugar; but not of cotton, for the foreign market is the regulator of the price of this very important article. Hence it may be said, that a money pressure at first has a tendency, by the great quantity of property forced into the market for sale, rather to increase, than diminish the number of exchanges. Whilst, however, the number of exchanges increase, the circulating medium suddenly becomes much more sluggish, taking the whole aggregate, in performing the functions of circulation. The great capitalists who are in the habit of purchasing produce with a view to sell with a profit, when prices are falling, rather keep aloof from the purchase of raw produce, least a further fall may injure them—their capital then circulates more slowly, and in consequence of it, the annual productions of the country are not distributed with that regularity, and adaptation to the various wants of the community, as under ordinary circumstances. The body politic, in this situation, is like a patient suffering congestion in one part of the system, while there is a depletion almost to the loss of vitality in another.

Again: bonds, bills of exchange, &c., ordinarily performing the larger portion of the circulation of every country, have now a much slower circulation, and consequently less efficacy in effecting the exchanges; because as there is a general loss of confidence and credit, A, who has sold to B, is distrustful of his bonds, his bills, in fine of credit in every shape—he wants money. Money too has generally a sluggish circulation on such occasions, for every one getting possession of it, is disposed to hold it as long as possible—hard money seems to be almost the only true friend which one can get hold of in such times as those, and is consequently held with a miserly grasp. Persons will not venture it out without the best security, and on high rate of interest, obtained either directly or indirectly.\*

\* An inconvertible bank paper is never hoarded in this manner. It is like fire in each man's hands, he wants to get rid of it as speedily as possible, lest it may be caught on him at a still lower point of depreciation. Hence the inconvertible paper of the Bank of England, in 1797, soon relieved the money pressure, but only to bring on evils greater still, as an inconvertible paper always will do.

Thus we find, first, that the number of exchanges has a tendency to increase during the first operation of a money pressure; and second, that the whole circulating medium of the country suddenly, from the very same cause, diminishes in the rapidity of its circulation, and therefore becomes less efficacious, as I have already proved.

**2nd. Effect of money pressure on actual amount of circulating medium.**—Let us now examine into the state of the circulating medium, and see whether, during a money pressure, it has any tendency to increase in quantity, so as to counteract the operation of the causes above specified. It is evident, first, that the money has no tendency to increase in quantity; because, first, the banks are distrustful of the credit of individuals, and of one another; the curtailment forced on one communicates to another, and finally all are obliged to curtail their accommodations and issues—hence a decided diminution in bank paper. Secondly, gold and silver in actual circulation diminishes in amount, because of the universal disposition to hoard, in consequence of loss of confidence. Thirdly, bonds and bills of exchange will generally diminish in amount, because these depend on credit altogether, and the first effect of the pressure is the destruction of confidence, and the ruin of the whole fabric of credit. Fourthly, stocks of every description diminish in value, or are entirely destroyed, by the disastrous operation of the times. Money, and not stocks, is what the times call for. And thus do we see, that while the exchanges increase, the circulation of the currency grows sluggish, and the quantity in actual circulation rapidly diminishes.

**Combined effect of these causes.**—What then, let me ask, is the effect of the combined operation of an increase in the number of exchanges, greater sluggishness in the circulation, and diminution of the whole circulating medium? Most undoubtedly, a continued fall in prices, until certain causes are thrown into operation, which will counteract this downward motion. Mr. Hume, in his History of England, says there is a point in the depression of nations, in the scale of circulation, below which they cannot sink. Amelioration will then spring out of the very disorder itself. So I would say in the disasters of trade and agriculture, there is a certain point of depression below which they cannot go. The self-sustaining energies of commerce are called into play, and apply the healing balm without the interference of government. Thus the causes, whose operation I have just been considering, gave a downward motion to prices in our country, until they reached that point which made this one of the worst markets in the world to sell in, and one of the best to sell from. The effect of this on foreign exchange will readily be perceived. More commodities were exported than imported. A money balance was created in favor of the nation. Hence a rapid and full current of the metals was soon seen flowing steadily into the country, and supplying the vast deficit in the circulating medium, occasioned by sluggishness of circulation, and diminution of the quantity from general destruction of confidence and credit. We all very well recollect, that a short time since, almost every paper announced the fresh arrivals of cargoes of gold and silver—and we know that, at this moment, we have more foreign coins in circulation than have been seen in the country for years past. The banks too seem generally to have drawn to their vaults large portions of the precious metals.

(To be continued.)

[From the Journal of the Franklin Institute.]

*Report to the Board of Directors of Bridges, Public Roads, and Mines, upon the Use of Heated Air in the Iron Works of Scotland and England. By M. DUFRENOY, Engineer of Mines. Paris, 1834.*

(Continued.)

#### ENVIRONS OF DERBY.

The coal basin of Derby, a prolongation of that of Sheffield, contains many large iron works; three of them, the Butterly, Codnor Park, and Alpdon works, have adopted the hot air blast. I visited the first two, under the charge of Mr. Jessop, one of the most intelligent iron masters in the kingdom. The heating apparatus of all these differ from those I have described, and, in some essential respects, from each other. For this reason, I have deemed it proper to describe them in detail, though the results which they give are not so favorable as those obtained at the Calder works.

*Butterly Iron Works* contains three smelting furnaces. The iron there made is intended for castings, either of first or second runnings. One furnace only was in blast when I visited Derbyshire. The air for the blast was heated by an apparatus at each tuyere; this apparatus was composed of the large pipes, A B C, (figs. 11 and 12,) 27 inches diameter in the clear, placed horizontally one over the other, and separated by arched plates, *m n, m' n'*. These pipes are connected in pairs, by elbow pipes, *d e, d' e'*. The air from the blast engine enters by the pipe *c*, and makes its exit at *g*, after having passed the length of the three pipes successively. The joints are placed on the outside of the furnace proper; but to prevent the air being cooled in traversing the elbows, they are cased in brick-work.

The elbows connecting the long pipes are in plates, connected by bolts and nuts, passing through lugs, or flanges. The pipes are one and a half inches thick, and rest upon fire lumps, *t t*, placed at proper distances upon the arch plates, *m n, m' n'*. This disposition allows the flame to envelope them on all sides.

The first pipe, A, is not exposed directly to the action of the fire; it is separated from the grate by an arch of brick, extending the whole length of the furnace, which allows the flame to pass by the flues, *v v*. The partitions, *m* and *n*, have openings, *p* and *q*, placed at the opposite ends of the furnace, so as to compel the flame to traverse the whole length, without escaping from one story to another. All the arches are of fire brick, one brick thick. The expenditure of this apparatus is 62 cwt. for each ton of casting made. The air is raised to 360° Fahr. Notwithstanding the feeble temperature, a great economy of fuel is effected, as indicated below.

Consumption and products during the first week in July, 1830, from furnace No. 2, worked with cold air; 159 tons 5 cwt. of coke,—corresponding to 218 tons 10 cwt. of coal, 109 tons 17 cwt. of ore, and 35 tons of flux,—produced 83 tons metal.

Consumption and products of furnace

No. 2, on the 17th of July, 1833, heated air being used: The furnace received forty-one charges, each composed of 9 cwt. crude coal, 9 cwt. ore roasted, and 3 cwt. flux. The average of the first fortnight in July had been forty charges per day, and the iron produced seven tons.

Upon comparing, from these data, the consumption of the two periods, one ton of iron required as follows:

1830. Cold air and coke—Coal, 5 tons 16 cwt.; ore, 3 tons; flux, 1 ton.

1833. Heated air and coal—Coal, 2 tons 18 cwt., including fuel to heat the air; ore, 2 tons 11 cwt.; flux, 1 ton.

To know the whole expense of fuel, that used by the blast engine must be added, for which I have no precise data; but this expense must necessarily diminish in proportion to the increased yield of the furnace.

At Butterly, therefore, a saving of one half the fuel has been effected by the introduction of the new plan. The quantity of flux remains the same, because the sulphurous nature of the coal requires a large proportion of lime.

The blast engine, which served but two furnaces, now works three; but to obtain this increase, a larger cylinder was put in. Formerly, the cylinder was seventy inches in diameter, and eight feet stroke, working thirteen revolutions; now, the cylinder is eighty inches, the length of stroke and number of revolutions remaining the same.

The quantity of air expended, which was 2,500 cubic feet per minute, is now reduced to 2,160 feet; but the pressure, two and a half pounds to the inch, has undergone no variation. The opening at the mouth of the tuyere has been reduced from two and a half to three inches; the iron produced is intended for castings.

*Codnor Park Works.*—This work consists of three furnaces, three refineries, and a sufficient number of puddling furnaces to work up all the metal. These furnaces have worked for the past year with heated air and crude coal. The substitution of heated air has produced a saving of fuel similar to that stated for Butterly; 2 tons 9 cwt. being now sufficient to obtain one ton of metal, which formerly required five tons. It should be remarked, that the expense of coal has always been less at Codnor Park than at Butterly, on account of the difference in the quality of iron produced. This difference would be much more sensible, if the same quality of coal was used at both works; but at Codnor Park the soft coal is used, while at the other a variety called cherry coal is used, which better resists the action of the blast.

Consumption for one ton, using cold blast: Butterly, 5 tons 16 cwt.; Codnor Park, 5 tons.

Same with hot air—Butterly, for smelting 2 tons 12 cwt., apparatus 6 cwt., total 2 tons 18 cwt.; Codnor Park, for smelting 2 tons 9 cwt., apparatus 6 cwt., total 2 tons 15 cwt.

The apparatus employed at Codnor Park, for heating the blast, is composed of two

pipes, A and B (figs. 13 and 14,) placed one above the other, in which are inserted small pipes, *a b*, having the same centres as the large pipes, A and B. These pipes are connected by elbows, so that the air, in passing from the blast engine, through the interior pipe, *b*, spreads itself over the circular space, *c d*, between the pipes B and *b*; passing then into the second interior pipe, *a* is transmitted to the furnace by traversing the second circular space, A. This disposition of double pipes, one within the other, was adopted to remedy a serious inconvenience experienced at Butterly,—an inconvenience incident to pipes of large diameter, in which the air being heated unequally, a current of cool air passes along the centre of the pipe, and renders it impossible to raise the temperature sufficiently.

The pipes, A B, are of cast-iron, thirty inches diameter outside, and one and a half inches thick; the small pipes, *a* and *b*, are of boiler iron, six-tenths of an inch thick, and eighteen inches diameter in the clear. The construction of the furnace is the same as at Butterly—figs. 13 and 14 giving an exact idea of it. The air is heated, by means of this apparatus, to 400° Fahr., with a consumption of 6 cwt. coal.

We have already stated that all the metal made at Codnor Park is made into malleable iron; \* this iron is used in the machine shops of Mr. Jessop. It serves equally well for boiler iron for steam engines, which requires the very best metal.

#### ENVIRONS OF BIRMINGHAM.

The introduction of the hot air blast has scarcely commenced in the Staffordshire iron district, the opinion being still prevalent that the quality of the iron is deteriorated by its use, has retarded the trial of it until within a year past. One work only, near Wednesbury, belonging to Messrs. Lloyd, Forster & Co., uses the heated air. The success attending this experiment determined the proprietors of the other works to make similar trials.

The apparatus employed here is placed above the trunnel head of the furnace, and is the only one at which such an arrangement has been effected in England. It is composed of a solid pyramidal ring, (figs. 15 and 16,) A B C D, and a series of small tubes, *t*, which penetrate into the furnace.

The interior surface of the ring, *a b c d*, is a cast iron cylinder, four feet in diameter, and twelve feet in height, in place of the chimney which usually surmounts the trunnel head of the furnace. The exterior surface of the pyramid is octagonal, and made of boiler plates, riveted together like a steam boiler, its diameter at the middle being six feet; a space is left between the surfaces of one foot on all sides; to protect the outer surface from the cooling action of the air, it is encased in brick-work.

The air, passing from the blast engine, is carried to the top of the furnace, circulates through the pipe, *e e e*, on a level with the top of the furnace, then divides

\* This is an error, as large quantities of pipes are cast at this work for the London market.—[Trans.]

Fig. 6.

Fig. 7.

Fig. 8.

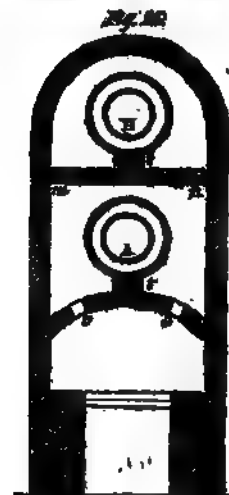

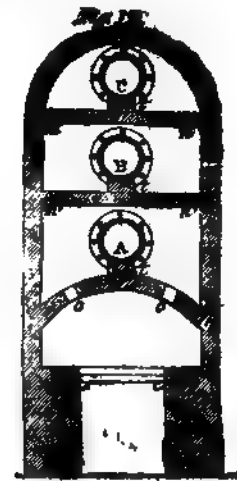

Fig. 15.

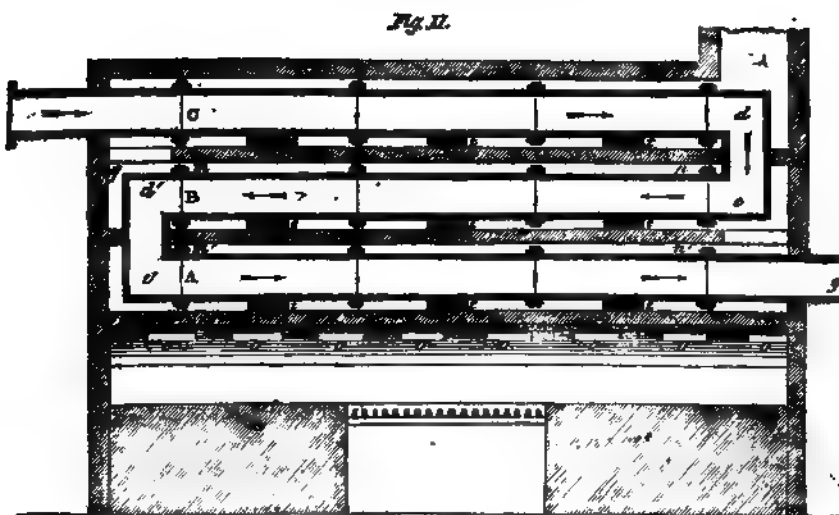

Fig. 16.

itself among the eight vertical pipes, *f g*, placed round the outer surface of the casing, which are connected with the circular pipe; each of these vertical tubes communicates with the interior of the case, or pyramid, by six small tubes, which pass into projections within the interior of the furnace.

The part of the tubes, *t*, enters into the pipes, *t*, closed at the extremity; so that the air, in moving, is forced to spread itself over the surface of the heater. These tubes, *t*, are all of cast iron, and are connected with the distributing pipes, *f g*, by leather sleeves, *t'*.

The air, after being heated in the tubes, *t*, and in the circular heater, A B C D, *a b c d*, re-ascends to the tuyeres by the opening, *v*. To prevent the air from cooling during the transit, the conductor is placed in the chimney of the steam boiler, twelve or fifteen feet distant; a kind of brick-work connects the furnace with this chimney.

With all these precautions, the temperature of the blast cannot be raised higher than to 360° Fahr., and they are obliged to heat it again in a furnace, within a few feet of the embrasure of the furnace.

The consumption of this fire is nearly 4 cwt. of coal to the ton of iron.

This apparatus is very costly, and requires frequent repairs; the little saving of fuel effected by it, (about 3 cwt. of coal per ton of iron,) is more than compensated for by the expense of construction and repairs, and, above all, by the numerous interruptions which take place in consequence of repairs required almost daily.

The introduction of hot air has effected, in these works, the same economy as in the others cited, where this plan is adopted. One ton of iron required, in 1831, 3 tons of coke, equal to 5 tons 9 cwt. of coal; now, the same quantity of iron consumes 2 tons 14 cwt. of coal, as the following statement shows:

On the 20th July, there passed through the furnace twenty charges, composed of 10 cwt. crude coal, 9 cwt. roasted ore, and 6 cwt. flux. The product being 8 tons of metal, each ton consumed 2 tons 10 cwt. coal for fusion, and 4 cwt. coal for heating the apparatus—total, 2 tons 14 cwt.; ore roasted, 2 tons 5 cwt.; flux, 1 ton 10 cwt.

The consumption in flux was considerable, because of the sulphurous nature of the ore. The slag which came from the furnace was crystalline, and gave off very strong sulphurous odors. Before the introduction of hot air, the daily production of the furnace was only six tons. They have, therefore, obtained, besides an economy in fuel, a diminution of the general expenses, and of labor. The quantity of blast has not been changed, but the tuyeres have been enlarged from 2 inches 9 lines, to 3 inches 6 lines.

Part of the iron produced at the works of Mr. Forster is used for the foundry, and part for fine metal; the same running gives both kinds of iron; that which flows first from the hearth, is No. 1 pig metal; the last running gives No. 2. They dis-

tinguish the two kinds of iron by the manner in which they run from the furnace, and by the furrows produced on the surface when it cools.

#### WALES.

There are in Wales but two works using the heated air—that of *Warteg*, and *Blaen-Avon*, ten miles from *Abergavenny*. None of the *Merthyr-tidvyl* works have introduced it, though the *Dowlais* and *Penn-y-danau* have made experiments thereon.

The abandonment of heated air in so extensive an iron country, and in which improvements are sought after with care, has led many to doubt the reality of the advantages claimed for it. Some have thought that, while so much saving was effected by the use of this plan in the furnaces of Scotland, where the metal was destined for the foundry, it could not be employed by other works, the product of which is converted into bar, or malleable, iron.

The examples furnished by the *Newcastle*, *Codnor Park*, and *Wednesbury* works, in which they make bar iron of very good quality, prove that this opinion is not well founded. The partial abandonment of the plan in Wales should, in part, be attributed to the bad construction of their heating apparatus, but more especially to the diminished saving which would result to them, since the employment of crude coal has been effected; a saving which the cost of the patent would almost balance. To appreciate these reasons, it is necessary to enter into some details upon the expense of making iron in that country.

From all the information gained upon the experiments made at *Dowlais*, or *Penn-y-danau*, it appears that, the apparatus being of bad construction, the temperature of the air could not be raised to more than 300° Fahr. Notwithstanding this, they attempted, with success, the substitution of crude coal for coke. An accident happening to the apparatus, obliged them to suspend the use of hot air for several days, and showed them that, without difficulty, the crude coal could be worked even with cold air. The saving which resulted from this substitution was such, that the proprietors did not deem it worth while to repair the heating apparatus, and thenceforth abandoned it. Since that period, most of the Welsh furnaces use the crude coal, but some employ a mixture of coal and coke.

The following table shows the quantity of fuel and material required to produce one ton of metal.

	Penn-y-danau.		Dowlais.		Cyfartha.		Plymouth.	
	t.	c.	t.	c.	t.	c.	t.	c.
Coal, . . .	2	9	2	14	2	13	2	13
Ore roasted, 2	4	0	2	9	2	6	2	16
Ashes, . . .	2	2						
Flux, . . .	19	2	13	0	16	0		

Add to this, the quantity consumed by the blast engines, about the same for each, varying from 5 to 6 cwt.

The average quantity of coal consumed in each of these works is, therefore, two and a half tons for each ton of iron. By the employment of heated air, it is not probable that a saving would be effected

over this expense of more than 33½ per cent., or 17 cwt. of coal for each ton of iron; deduct from this, the fuel consumed to heat the apparatus, estimated at 6 cwt., and the actual saving would be reduced to 11 cwt., costing, at 3s. 7d., or 86 cents per ton, at the works, 44 cents; and as the patent right is charged at one half, or 24 cents per ton of iron, the saving would be diminished to 20 cents per ton. This economy, itself very small, would scarcely be appreciated in a district where all the materials are so cheap, that iron may be produced at a less price than in any other district in Great Britain.

I believe, therefore, that the non-adoption of this plan in Wales, is no evidence that it does not effect any saving in fuel; but, on the contrary, it leads me to think that there would be economy, as in other works where the plan is used; but it is evident that, the expense\* of coal being very small in Wales, the economy would not be as marked as in the works of Scotland.

The *Warteg Iron Works*, which have been named at the beginning of this section, sustain this opinion. In this establishment, the heating apparatus is composed of a very short development of pipes, so that the air cannot acquire a temperature of more than 400° Fahr. The coal, which is very bituminous, and loses 55° per 100 in the coking, cannot be employed crude in the furnace, with the air at so low a temperature; it results from these circumstances, that the saving obtained is not so great as at the furnaces of Scotland, but is to be compared to the saving in those works where the apparatus is not so perfect, and where coke is still used. Nevertheless, the diminution in the cost is very marked: before the introduction of heated air, one ton of iron required a consumption of two tons of coke; the produce of four tons, three cwt. of coal. The consumption of coke is still about the same, but, as there is no necessity for carbonizing it so completely, it is now produced by only three tons of coal.

The yield of the furnace has been augmented from six to eight tons of iron, each, in twenty-four hours.

\* The author should have attributed this difference, in a great degree, to the superior quality of the Taff Vale coal over the Scotch, the former yielding more than 75 per cent. of carbon, while the proportion in the latter is less than 65 per cent.; some varieties even as little as 51 per cent.—(Trans.)

AGRICULTURE, &c.

**On Budding Trees and Shrubs.** By the CONDUCTORS. To which is added, the different modes of Budding; and of Herbaceous, or Summer Grafting, extracted from Loudon's Gardener's Magazine.

(Continued from our last number.)

13. *Escutcheon Budding, with a Portion of Terminal Buds; Greffe en Escusson par Portion d'Yeux terminaux.* (fig. 10).—A piece, measuring six or eight lines in length, cut from the top of a branch, is split in two, dividing the terminal bud exactly in the middle. An incision is then made in the stock in the form of a T, and the half bud is inserted into it in the usual manner. In case of need, the terminal eye might be divided into four equal parts. The growing bud ought to be used to insure success, though this mode will sometimes succeed with a dormant bud. This method may be very useful, if the tree to be propagated

has no young side shoots strong enough to admit of a bud being taken from them. It is particularly suitable for rare trees, with scaly buds and opposite branches.

14. *Annular Flute Budding; Greffe en Flute en Anneau.* (fig. 11).—A branch is chosen on the tree which is to be propagated, as thick as, or thicker than, the stock, and a ring of bark, including an eye, is cut from it, and detached by splitting it perpendicularly on one side, and then separating it from the wood by inserting under it the spatula-like handle of the budding-knife. A similar operation is then performed on the stock; that is to say, a ring of bark, exactly of the same size, is detached from the stem in the same manner, but without caring whether there are buds on it or not. In its place is put the ring taken from the branch to be propagated, with the precaution of making the inner barks join together exactly both at top and bottom. No binding is applied; but the whole is covered with grafting-clay (*onguent de St. Fiacre*) or grafting-wax. Neither the branches nor the head of the stock are to be cut down till the bud has taken. The two periods most favorable for this sort of budding are, the time of the greatest movement of the sap in the spring, and at the end of its greatest movement in August. This mode of budding has the advantage of never mutilating the stock; because, if it does not take, the bark of the ring supplies the place of that taken away. It is not only suitable for the propagation of walnut trees, but also for the increase of all rare trees with hard wood, such as the American oaks and chesnuts.

15. *Split Flute Budding; Greffe en Flute fendue.*—The only difference between this and the preceding mode is, that, if the ring of bark containing the bud is larger than the space prepared for it on the stock, a piece must be taken from it longitudinally, so as to make it fit exactly.

16. *Flute Budding by close Contact, Tube Budding; Greffe en Flute par juxtaposition, ou en Sifflet.*—The head of the stock being cut off, a ring of bark, 2 in. or 3 in. long, is removed. A shoot is then taken from the tree to be increased, of exactly the same thickness as the stock, and a ring or tube of bark is taken off the thick end, without being split longitudinally, not

quite so long as the piece of bark taken off the stock, but provided with two or three good eyes. The tube thus formed is placed upon the stock in the room of the one taken away, and care is taken to make the two edges of bark join below. The part of the stock which projects over the ring of bark is next split into shreds, and brought down over it all round, so as, when secured by grafting-clay, to keep it in its place. This mode of budding is chiefly employed in the south of France for propagating walnuts, chesnuts, figs, mulberries, and other trees with thick bark and abundant pith.

17. *Common Flute Budding; Greffe en Flute ordinaire.* (fig. 12).—The head of the stock is cut off; but, instead of removing a ring of bark, as in the preceding mode, it is cut longitudinally into four or five strips, each 2 in. or 3 inches long, and turned down as in the figure, being left still attached to the tree. From a shoot of the tree to be propagated, a tube of bark is taken, furnished with four or five eyes, rather shorter than the strips, though longer than in tube budding. When the tube of the scion is slipped on the stock, the strips of bark are raised over it, and fastened at the top by a ligature. This method of budding is in very general use both in France and Germany.

18. *Flute Budding in Shreds, with the Stock cut obliquely; Greffe en Flute et en Laniere.*—This is nothing more than the mode above described, with the end of the stock cut obliquely, as shown at a in fig. 12, instead of being left to be afterwards cut into shreds and turned down over the tube of bark, as in tube budding, No. 16.

II. HERBACEOUS GRAFTING. *Greffe Herbacee.*

1. *Grafting upon fleshy or tuberculous Roots; Greffe sur Racines charnues ou tuberculeuses.* (fig. 13).—It not unfrequently happens that a tubercle of a georgina root is found without eyes; and, when this is the case, notwithstanding all the care of the cultivator, it may remain in the ground one or two years without budding, till at last it rots. This imperfection is easily discovered if the neck of the tuber is looked at attentively, for it is always there that the buds are found. In this case, as soon as a georgina bud upon some other tuber has begun to germinate, it is picked out with the point of the grafting-knife, and is taken away with a small piece of the tubercle adhering to it. On the neck of the barren tubercle a small hole is made, in which the bud is inserted, but in such a manner as that the base of the bud shall be perfectly on a level with the surface of the tubercle; and it is cemented with grafting-wax. The tubercle is then planted in a pot, taking care not to cover the neck on which the graft is, and the pot is plunged in a hot-bed, under glass. When the graft has taken properly, the plant is turned out into the open border.

2. *Herbaceous Furrows-Grafting for vertical Shoots; Greffe herbacee en Rainure pour les Omnitiges.* (fig. 14).—A bud with a triangular slice of bark and wood, when in a soft or herbaceous state, is cut out of the

scion, and inserted in a corresponding groove made in the stock, as shown in the figure; a ligature is applied, and afterwards grafting-wax. This mode of grafting succeeds both with the young wood of trees and with herbaceous plants, whether perennials or annual. M. Tschoudy gave the arbitrary name of *omnitiges* to those plants, the shoots of which have an equal tendency upwards, and which, of course, are equally suitable to graft upon.

3. *Herbaceous Grafting for Shoots with opposite Leaves; Greffe herbacee pour les Bourgeons a Feuilles opposees.* (fig. 15).—In the middle of the stem, between two opposite eyes, an angular and longitudinal incision is made, traversing the stem from one side to the other. The graft is cut angularly at its top and bottom, and it is inserted as in the figure. The binding, &c., is then put on as usual. This mode of grafting is suitable for those species of trees, and

annual or perennial plants, the buds of which are opposite on the stem, which happens most frequently on the central shoots of plants. M. Tschoudy gives the name of *multitiges* to those plants, the central shoots of which have a tendency to rise more vertically than the lateral ones, and which have consequently more vigor; it is upon these central shoots that the grafts ought to be made.

4. *Grafting on the Stem of Annual or Perennial Plants; Greffe sur Tige de Plantes Annuelles ou Vivaces.* (fig. 16).—The period chosen for this mode of grafting is that of the greatest vigor of the plant, that is, some days before its going into flower. The stem of the stock is cut through above a leaf, as near as possible to its petiole, and a slit downwards is made in the section. A shoot is then taken off near the root of the plant to be increased, the end of which is cut into a wedge shape, and is inserted in the slit made in the stock, taking great care of the leaf on the latter; for it is that which must nourish the scion until it has taken thoroughly, by keeping up the circulation of the sap. A bandage is applied, and the junction covered with grafting-wax, as before. When the graft has taken, which is ascertained by its growth, the ligature is removed, and the old leaf, and the shoots from the stock below the graft, are removed. M. Tschoudy grafted in this manner artichokes upon cardoons, and other plants on their congeners.

5. *Grafting on Succulents; Greffe des Plantes Grasses.* (fig. 17).—Take a young shoot or leaf of a succulent plant, (i. e., of a cactus or opuntia,) and, cutting its base to a point or wedge, insert it in a hole or slit made in the stem or leaf of another species, but of the same genus.

8. *Grafting the Melon; Grafte du Melon*, (fig. 18.)—On the stem of a cucumber, or any other plant of the family of Cucurbitaceae, but having some analogy with the melon, choose a vigorous part of a shoot having a well-developed leaf. In the axil of this leaf an oblique cut is made, of half its thickness. The point of a melon shoot, so far developed as to have its fruit quite formed, is then cut off, and pointed at its end, & is inserted in the ways taking care scion has taken. operation is per- r, with ligatures node of grafting t has not hither- ul end. Toma-

atoes, and it is said that potato plants thus treated produce good crops both of potatoes and tomatoes.

*Grafting-wax* may be formed with turpentine, bees' wax, resin, and a little tallow, melted together. It may either be put on in the same manner as grafting-clay, but not more than a quarter of an inch in thickness; or it may be very thinly spread upon cotton cloth, and used in shreds like sticking-plaster. In this last state it serves both as a ligature for retaining the es- cutcheon or scion in its place, and as a covering for excluding the air. In very delicate budding and grafting, fine moss and cotton wool are frequently used as substitutes for grafting-clay or grafting-wax; the moss or cotton being tied firmly on with thread or strands of bast matting.

[Extract from the Massachusetts Agricultural Repository, &c.]

*List of the Forest Trees of America, described in the work of M. Andre F. Michaux.*

[The botanical name of each tree is first given, followed by the most common American name. The vulgar names used in various parts of the United States, or Canada, next follow.]

*Pinus rubra*, Red pine.—Red pine, only name given to this tree in Canada; often used in Nova Scotia and New Brunswick, and in Maine. Norway pine, name more generally in use for this tree than the above, in the district of Maine, New-Hampshire, and Vermont, but less proper. It is not the Norway pine, says Michaux. Yellow pine, name sometimes given to it in Nova Scotia. Pin rouge, or red pine in Canada. Michaux prefers red pine, as being more characteristic and distinct.

*Pinus rupestris*, Gray pine.—Gray pine, in Canada, by the French and English. Scrub pine, in Nova Scotia and Maine. Uncommon and ordinary. Michaux.

*Pinus mitis*, Yellow pine.—Yellow pine, general name in all the middle states. Short-leaved pine, in the southern states. Spruce pine, a secondary name in these last mentioned states.

This is described by Michaux as a pretty valuable tree, ranking after the red pine, which is again put far behind the long-leaved or pitch pine of the south, and the white pine of the north.

*Pinus inops*, Jersey pine.—Jersey pine, general name in New-Jersey, where it abounds. Scrub pine, the name given to it in Virginia, and in those parts of Pennsylvania where it is found.

*Pinus pungens*, Table-mountain pine.—Table-mountain pine, the only name given to it in the neighborhood of that mountain, in North Carolina.

*Pinus australis*, Long-leaved pine.—Yellow pine. Long-leaved pine. Pitch pine, (not the pitch pine of the north.) Broom pine. All which names are more or less used in the lower parts of the southern states, where alone this tree grows. Southern pine and red pine, are the names given to it in the middle and northern states, by those who use it. Georgia pitch pine, name given to it in the West Indies, and in England.

*Pinus serotina*, Pond pine.—Pond pine, name given by M. Michaux to this pine, which has none given to it in the southern states, where he found it.

*Pinus rigida*, Pitch pine.—Pitch pine, general name in all the northern and middle states. This is the true pitch pine of New-England, but very different from the pitch pine of the south.

*Pinus taeda*, Loblolly pine.—Loblolly pine, only name in the southern states. White pine, sometimes so called in the neighborhood of Petersburg, Virginia.

*Pinus strobus*, White pine.—White pine, only name given to this tree in the greater part of the United States, and in Nova Scotia and New-Brunswick. Pumpkin pine and sapling pine, names sometimes given to it in Vermont, New-Hampshire, and Maine, in reference to the quality of its wood. Pin blanc, or white pine, by the Canadians. Weymouth pine, in England.

*Abies nigra*, Black spruce, (double spruce).—Black, or double spruce, name used in the northern states, in Maine, and Nova Scotia. Red spruce, in the same countries, having regard, however, to trees of larger size than usual, or to certain places of growth. *Epinette noire*, in Canada. *Sapinette noire*, in France.

*Abies alba*, White spruce.—White, or single spruce, names applied in the northern states, and in Nova Scotia. *Epinette blanche*, in Canada. *Sapinette blanche*, in France.

*Abies canadensis*, Hemlock spruce.—Hemlock, or hemlock spruce, only denomination in use in all parts of the United States, where this tree is found. *Perusse*, by the Canadians.

*Abies balsamifera*, Silver fir.—Silver fir. Fir balsam. Balm of Gilead. All names equally applied to this tree in the northern parts of the United States.

*Juglans nigra*, Black walnut.—Black walnut, only name in the southern and western states. *Noyer noir*, by the French of Canada and Louisiana.

*Juglans cathartica*, Butter nut.—Butter nut, only name in New-York, and Virginia, and often applied in the northern states. White walnut, name much in use in Pennsylvania and Maryland. Oil nut, name applied in New-Hampshire, Massachusetts, Vermont, and Connecticut.

*Juglans olivæ-formis*, Pacane nut.—Pacane nut, or pacanier, name given to this

tree by the French of Louisiana, and adopted by the Americans.

*Juglans amara*, Bitter nut hickory.—Bitter nut hickory, only name applied to it in New-York and New-Jersey. White hickory, general name in Pennsylvania. *Noyer amer*, Canadian name.

*Juglans aquatica*, Water bitter nut hickory.—Water bitter nut, name given to it by Michaux. It has no name in the southern states, where it grows.

*Juglans tomentosa*, Mockernut hickory.—Mockernut hickory, general name in New-York and New-Jersey. Whiteheart hickory, name sometimes applied in those states. Common hickory, applied in Pennsylvania, Maryland, and other southern states. *Noyer dur*, by the French of the Illinois country.

*Juglans squamosa*, Shellbark hickory.—Shellbark hickory, name in most common use in the United States. Shagbark hickory, name sometimes applied to the north of Connecticut river. *Kiky Thomas*, by the Dutch of New-Jersey. *Noyer tendre*, by the French of Illinois.

We think M. Michaux mistaken on this point. It is the common walnut of our tables, and is almost universally called shagbark. In all the northern states, we know this tree by the name of walnut, and not hickory, which is a southern name.

*Juglans laciniata*, Thick shellbark hickory.—Thick shellbark hickory, name given to this tree in the western states, where it is confounded with the true shall, or shagbark. Gloucester-nut hickory, known under this name only in that part of Virginia. Springfield hickory, another name given to this tree in the vicinity of Philadelphia.

*Juglans porcina*, Pignut hickory.—Pignut hickory, most common name in all parts of the United States. Hognut hickory, more usual name in some districts of Pennsylvania.

*Juglans myristicaformis*, Nutmeg hickory-nut.—Nutmeg hickory-nut, name given to it by M. Michaux, it having no name in the southern states.

*Quercus alba*, White oak.—White oak, general and unique name throughout the United States. *Cheneblanc*, by the Canadians.

*Quercus mucronata*, Mossy cup oak.—Mossy cup oak, name given by M. Michaux to a species found in the Genesee country, and near Albany.

*Quercus macrocarpa*, Overcup white oak.—Overcup white oak, general name given to it in Kentucky and Tennessee.

*Quercus obtusiloba*, Post oak.—Post oak, general name in both Carolinas, Georgia, and Tennessee. Iron oak, secondary name in those countries. Box oak and box white oak, name given to it in Maryland, and the parts of Virginia bordering on it.

*Quercus lyrata*, Overcup oak.—Overcup oak and swamp-post oak, names equally used in the lower parts of the southern states. Water white oak, secondary name in the same places.

*Quercus prinus discolor*, Swamp white oak.—Swamp white oak, most common name in the northern and middle states. Water-chestnut oak, Pennsylvania name.

*Quercus prinus alutris*, Chestnut white oak.—Chestnut white oak, name applied in the lower parts of Georgia, and the Carolinas. White oak, peculiarly so called on the Savannah river. Swamp-chestnut oak, secondary name in the same places.

*Quercus prinus monticola*, Rock-chestnut oak.—Rock-chestnut oak, only name given to this tree in New-York and Vermont. Rock and rocky oak, second name in the same countries. Chestnut oak, in Pennsylvania and Virginia.

*Quercus prinus acuminata*, Yellow oak.—Yellow oak, name given to this tree in the county of Lancaster, Pennsylvania. No particular name given to it in other parts of the United States.

*Quercus prinus chinquapin*, Chinquapin oak.—Chinquapin oak, name employed in the upper parts of Georgia and the Carolinas. Small-chestnut oak, in New-York and Pennsylvania.

*Quercus virens*, Live oak.—Live oak, only name in all the southern states; and also in the northern states, where the wood is only seen, but the tree is never found.

*Quercus phellos*, Willow oak.—Willow oak, only name in the southern states, and in Pennsylvania.

*Quercus imbricaria*, Laurel oak.—Laurel oak, secondary name in the states west of the Allegany mountains. Black-jack oak, more common, but less proper name, because it is applied to another, for which it is kept distinct. Chene a latte, by the Illinois French.

*Quercus cinerea*, Upland willow oak.—Barren's willow oak, name given in the lower parts of the southern states.

*Quercus pumila*, Running oak.—Running oak, in the lower parts of the southern states.

*Quercus heterophylla*, Bartram's oak.—Bartram's oak, name given to an oak on the Schuylkill, near Philadelphia.

*Quercus aquatica*, Water oak.—Water oak, general name in Virginia, and in the southern states.

*Quercus ferruginea*, Black-jack oak.—Black-jack oak, name in use in the southern states. Barren's oak, name employed in Pennsylvania, New-Jersey, and Delaware.

*Quercus banisteri*, Bear oak.—Bear oak, name in New-Jersey and New-York. Black scrub oak, name used in the north of Connecticut river. Scrub oak, in some parts of Pennsylvania and Virginia.

*Quercus catisbei*, Barren's scrub oak.—Barren's scrub oak, in the lower parts of the two Carolinas and Georgia.

*Quercus falcata*, Spanish oak.—Spanish oak, only name in use in Pennsylvania, Maryland, and Virginia. Red oak, in the lower parts of the southern states.

*Quercus tinctoria*, Black oak.—Black oak, only name in the forests of the middle, western, and southern states. Quercitron oak, name in commerce. Chene noir, by the Illinois French.

*Quercus coccinea*, Scarlet oak.—Scarlet oak, name given by M. Michaux to a tree, which, in the middle states, bears the name of red oak, being confounded with a species hereafter mentioned.

*Quercus ambigua*, Gray oak.—Gray oak, only name given to this species in

New-Hampshire and Vermont, as well as in the district of Maine, New-Brunswick, and Nova Scotia.

*Quercus palustris*, Pine oak.—Pine oak, name given to this species in New-York and New-Jersey. Swamp Spanish oak, in Pennsylvania and Maryland.

*Quercus rubra*, Red oak.—Red oak, name given to this oak in all the northern and middle states.

In all 27 species of oaks.

*Betula papyracea*, Canoe birch.—Canoe and paper birch, names equally used in New-Hampshire, Vermont, district of Maine, Nova Scotia, and further north. White birch, name also equally applied in the same countries. Bouleau a canot, by the French in Canada.

*Betula populifolia*, White birch.—White birch, general name in the northern and middle states. Old-field birch.

*Betula rubra*, Red birch.—Red birch, so called in New-Jersey and some parts of Pennsylvania. Broom birch, secondary name in Pennsylvania. Birch, in the southern states.

*Betula lenta*, Black birch.—Black birch, denomination applied to it in the northern and middle states. Cherry birch, secondary name in some parts of the northern states. Sweet birch, in the middle states. Mountain mahogany, in a part of Virginia. Cherry birch. Bouleau cerisier, by the Canadians.

*Betula lutea*, Yellow birch.—Yellow birch, name given to this species in Vermont and New-Hampshire, as well as in Maine and New-Brunswick.

*Castanea vesca*, Chestnut.—Chestnut, only name given to it in all parts of the United States where it grows.

*Castanea pumila*, Chincapin.—Chincapin, only denomination given to it in the middle, southern, and western states.

*Fagus sylvestris*, White beech.—Beech, in the middle and southern states. White beech, in the northern states and district of Maine.

*Fagus ferruginea*, Red beech.—Red beech, in the northern states, and district of Maine.

*Chamærops palmeto*, Cabbage tree.—Cabbage tree, or palmetto, in the southern states. This tree is extensively used in the construction of wharves in Charleston, South Carolina, being free from the ravages of the worms.

*Ilex opaca*, American holly.—American holly, so called in all the parts of the United States where it grows.

*Diospiros virginiana*, Persimmon tree.—Persimmon, only name in those parts of the United States where it is found, being in the middle and southern states. Plaque-minier, by the Louisianians.

*Acer eriocarpum*, White maple.—White maple, only name on the borders of the Ohio, and the rivers which fall into it. Soft maple, in the Atlantic states, where it is often confounded with the scarlet maple. Sir wager maple, name applied to it in England, where it has been introduced.

*Acer rubrum*, Red-flowering maple.—Red-flowering maple, Swamp maple, Soft maple, denominations in the Atlantic states. Scarlet-flowering maple, principally in Virginia, and soft maple in New-York and

New-Jersey. Maple tree, in Pennsylvania, Virginia, and Ohio, to the west of the Allegany mountains. Erable plains, by the Canadians.

*Acer saccharinum*, Sugar maple.—Sugar maple, general name, which, however, prevails only in the middle states, to the east of the mountains. Rock maple, name which prevails to the north of the Hudson river. Hard maple, another name in the northern states. Erable sucre, Canadian name.

*Acer nigrum*, Black sugar maple.—Sugar tree, general name in the country on the Ohio, and the Rivers which fall into it; and often applied also there to the last mentioned species. Black sugar tree, name sometimes applied, and to be preferred.

*Acer negundo*, Box elder.—Box elder, only name in the western states where the tree is most known. Ash-leaved maple, name given sometimes in the Atlantic states. Erable a giguiers, by the Illinois French.

*Acer striatum*, Moose wood.—Moose wood, common name in all the northern states, in New-Brunswick, and Nova Scotia. Striped maple, by some persons in the middle states.

*Nyssa grandidentata*, Large tupelo.—Large tupelo, most general name in the southern states. Water tupelo, secondary name in the same states.

*Nyssa capitata*, Sour tupelo.—Sour tupelo, in Georgia.

*Nyssa sylvatica*, Black gum.—Black gum tree, in all the states to the south of the Delaware. Sour gum, secondary name in the same states. Peperidge, by the Dutch of New-Jersey.

*Gymnocladus dioica*, Coffee tree.—Coffee tree, only name given in the western states. Chicot, by the Canadians. By some botanists called guilandina dioica.

*Pinckneya pubens*, Georgia bark.—Georgia bark tree, name given by M. Michaux; it is known by no name in that country.

*Cupressus disticha*, Cypress.—Cypress, general name in the United States. It is not known at all in the northern states, except in modern plantations, and there called deciduous cypress. Bald cypress, name less used. Black or white cypress, having regard to the color of the wood.

*Cupressus thuyoides*, White cedar.—White cedar, only name in the states of New-York, New-Jersey, Delaware, and Pennsylvania. Juniper, in Maryland, Virginia, and North Carolina.

*Thuja occidentalis*, Arbor vitæ.—Arbor vitæ, secondary name in the District of Maine. White cedar, name more used in Maine, Vermont, and New-Hampshire. Cedreblanc, by the Canadians.

*Larix americana*, American larch.—American larch, general name given to this tree in all parts of the United States where it grows. Hackmatack, more used in the north, and in the district of Maine. Tamarach, by the Dutch of New-Jersey.

N. B.—This tree is very seldom called by the name of larch in New-England, and in some districts it is called Juniper.

(To be continued.)

## NEW-YORK AMERICAN.

JULY 11—17, 1835.

## LITERARY NOTICES.

THE PRIMITIVE CHURCH compared with the Protestant Episcopal Church of the present day, &c. &c. By JOHN HENRY HOPKINS, D. D., Bishop of Vermont. 1 vol. Burlington—Smith & Harrington.

Episcopalians will receive this book with gratitude, for it ably and clearly vindicates the doctrine, worship and government of the Episcopal Church in this country, and satisfactorily meets, and refutes; the popular objections against it.

To Bishop Hopkin's book must be conceded, we apprehend, the merit of a clear and popular style, of an earnest spirit, of close argument, and, as it strikes us, of clear demonstration.

DANGER OF BEING OVERWISE, a Sermon preached 7th June, 1835, in the Second Presbyterian Church of Albany; by WM. B. SPRAGUE, D. D.: Albany PACKARD & VAN BENTHUSEN.—This is a bold sermon—an odd epithet it may be said to apply to a discourse from the pulpit—yet in this instance a just one. It is an act of great moral courage, under the circumstances in which we live, for a clergyman of the Presbyterian Church especially, thus to come forth, and breast the intemperate zeal, with which the good and noble cause of temperance is sometimes urged on. Mr. Sprague, however, under a strong sense of duty, and let us add under an act, as we have heard it related, of great provocation, has done this, and done it well.

BELFORD REGIS, or sketches of a county town by MARY RUSSELL MITFORD; 2 vols: Phila., CAREY, LEA & BLANCHARD.

Miss Mitford in this new work has enlarged her sphere of action, and passed from "our village" to a busy bustling market and county town—with all its characters, and peculiarities, and memories. She loses nothing of freshness or force in this series, as the following extract may in part testify. It is of past times—when the plague was desolating London, and *Belford Regis*, and its neighboring villages had caught the infection from city fugitives. "*Master Anthony*"—had brought up *Rosamond* with doating fondness, which she had requited, by running off against his will, with a young Court gallant, and no intercourse had taken place between them until the moment of the scene we quote, when "*Master Anthony*" after exhausting himself in attending upon the deserted and the dying, is, in his own hour of need and danger, robbed and abandoned.

THE MONIKINS: edited by the author of the "*Spy*"—2 vols: Phila., CAREY, LEA & BLANCHARD.—Of the multitude of persons into whose hands this new work of Mr. Cooper may fall, we doubt if more than one in fifty will achieve what we have, the actual perusal of the two mortal volumes. We have as a matter of duty and conscience, read page by page their some 500 pp. with all attention—save when failing nature gave way under the effort, and words upon words passed before the eye, but reached not the understanding. A more lamentable failure than this book—from the hand of an established and practised writer—the annals of literature do not, we apprehend record.

So far as we can comprehend the scope of the story, it is to ridicule and satirize mankind at large, by a clumsy contrivance of a monkey land, and monkey inhabitants, where, and among whom, the vices, pretensions, prejudices and follies which disturb and degrade man, are in full operation.

After the travels of Capt Lemuel Gulliver, this were a dangerous experiment, even to a writer em-

inently gifted with humor, but of this gift the author of the *Spy*, has but little share, and instead, therefore, of the fine irony, and sparkling satire, and strong and admirable contrasts to be found in the pages of Swift, we have dull and prosing dissertations about theogony, cosmogony, law, politics, education, paper currency, the removal of the depositories, aristocracy, democracy, the Godlike, &c. &c., with a sprinkling of nastiness (in that alone, resembling Swift,) about monkey's tails, and the place where men should have them—which altogether defy criticism, and will, we think, very thoroughly and soon disenchant all readers.

The story, so far as there is one, is shortly this. A rich old stock-broker dying, leaves as the sole heir to his immense wealth, a foundling, whom he had adopted and called his own—a goodly block-head, who sets forth in the world immediately, to give pledges to fortune as Bacon has it, not by marrying the woman of his affection, for that, our philosopher argues, would be idolatry, but by taking an interest in all the pursuits of all mankind.—Wandering about with this chimerical design, he meets in Paris, Capt. *Noah Poke*, of Stonington, a Yankee Sealer. They become sworn friends, rescue four monkeys, exhibiting by some Savoyards, and are rewarded for their humanity, by learning from the gravest and eldest of the interesting beings they had emancipated, that he is a learned Doctor from the Academy of Monikinia, in Monkey land, travelling with two young nobles of his nation, who are betrothed to each other, that his female companion is the young lady's duenna, and that they had all been ingloriously kidnapped, and forced to dance for their living. All this being communicated in good French—though spoken with a slight Russian accent—a great intimacy ensues between the parties, which results in the English *Golden Calf*, fitting out a ship under the command of Capt. *Poke*, to re-convey these ill treated innocents of the genus *Simiar*, to their native land.—Thither, too, goes *Golden Calf*, and after innumerable perils and difficulties in penetrating the ice, around the southern pole, they reach the desired land, and there occur the wonderful dissertations to which we have alluded.

MATTHIAS AND HIS IMPOSTURES, or the Progress of Fanaticism, &c. &c., by WM. L. STONE, 1 vol. N. Y., HARPER & BROTHERS.

Poor human nature! What a picture does this very curious, and as we do not doubt authentic, volume, present of the boasted intellect of man; what a stinging satire does it hold forth, of the vaunted advance of education, of sound and liberal views, of the progress of reason, and of the growth of genuine religion. A miserable, ignorant, brutal, selfish, and overbearing impostor subjects to his will, whole families of educated people, and lords it over them in sickness and in health, with unbridled insolence, giving himself out as God, and as such received!

But the imposture of Matthias is not the only one here recorded, for it was preceded and prepared, it seems, by fanatical meetings and assemblages held constantly for many preceding years—where all sorts of delusions prevailed. If only as a warning against fanaticism, this book should be generally read.

THE COMPLETE POETICAL WORKS OF WALTER SCOTT. 1 vol. 8vo. New York. CONNER & COOKE.—This is an exceedingly handsome and well finished volume, containing *Sir Walter's* Poems, lyrical as well as others, with copious notes and explanations. It is very creditable to the publishers, and may, we hope, be profitable.

SPECIMENS OF THE TABLE TALK OF THE LATE

SAM'L T. COLERIDGE. Two volumes in one. N. York. HARPER & BROTHERS.—We have only time to acknowledge the reception of this work, and to say, what we are sure, a future perusal of it will verify, that if it retain any portion of the spirit of the talk of the most gifted talker of the age, it must be a book of deep interest and attraction. We have read with pleasure and conviction, the well deserved castigation bestowed by the Editor, on the inconceivable base notices of Coleridge, published in Tait's Magazine, by the English opium eater.

[From the *Athenæum*.]

Mrs. Hemans.

Felicia Dorothea Browne was born in Liverpool, in a small quaint-looking house in St. Anne street, now standing, old fashioned and desolate, in the midst of the newer buildings by which it is surrounded. Her father was a native of Ireland, her mother a German lady—a Miss Wagner—but descended from, or connected with, some Venetian family, a circumstance which she would playfully mention, as accounting for the strong tinge of romance and poetry which pervaded her character from her earliest childhood. Our abstaining from any attempt minutely to trace her history, requires no apology—it is enough to say, that when she was very young, her family removed from Liverpool to the neighborhood of St. Asaph, in North Wales; that she married at a very early age—that her married life, after the birth of five sons, was clouded by the estrangement of her husband—that, on the death of her mother, with whom she had resided, she broke up her establishment in Wales, and removed to Waverree, in the neighborhood of Liverpool—from whence, after a residence of about three years, she again removed to Dublin,—her last resting place.

But though respect for the memory of the dead, and delicacy towards the living, enjoin us to be brief in alluding to the events of her life, we may speak freely, and at length, of the history of her mind, and of the circumstances of her literary career, in the course of which she deserved and acquired a European reputation as the first of our poetesses living, and still before the public. Few have written so much, or written so well as Mrs. Hemans; few have entwined the genuine fresh thoughts and impressions of their own minds, so intimately with their poetical fancies, as she did; few have undergone more arduous and reverential preparation for the service of song; for, from childhood, her thirst for knowledge was extreme, and her reading great and varied. Those who, while admitting the high-toned beauty of her poetry, accused it of monotony of style and subject (they could not deny to it the praise of originality, seeing that it founded a school of imitators in England, and a larger one in America) little knew to what historical research she had applied herself—how far and wide she had sought for food with which to fill her eager mind. It is true, that she only used a part of the mass of information which she had collected—for she never wrote on calculation, but from the strong impulse of the moment, and it was her nature intimately to take home to herself and appropriate only what was high-hearted, imaginative, and refined; but the writer of this hasty notice has seen manuscript collections of extracts made in the course of these youthful studies, sufficient of themselves to justify his assertion; if her poems (like those of every genuine poet) did not contain a still better record of the progress of her mind. Her knowledge of classic literature may be distinctly traced in her "*Sceptic*," her "*Modern Greece*," and a hundred later lyrics based upon what Bulwer so happily calls "*the Graceful Superstition*." Her study and admiration of the works of ancient Greek and Roman art, strengthened into an abiding love of the beautiful, which breathes both in the sentiment and structure of every line she wrote (for there are few of our poets more faultlessly musical in their versification;) and when, subsequently, she opened for herself the treasures of Spanish and German legend and literature, how thoroughly she had imbued herself with their spirit may be seen in her "*Siege of Valencia*," in her glorious and chivalresque "*Songs of the Cid*," and in her "*Lays of Many Lands*," the idea of which was suggested by Herder's "*Stimmen der Volker in Liedern*."

But though her mind was enriched by her wide

acquaintance with the poetical and historical literature of other countries, it possessed a strong and decidedly marked character of its own, which colored all her productions—a character which, though any thing but feeble or sentimental, was essentially feminine. An eloquent modern critic (Mrs. Jameson) has rightly said, "that Mrs. Hemans' poems could not have been written by a man; their love is without selfishness, their passion without a stain of this world's coarseness, their high heroism (and to illustrate this assertion we would mention "Clotilda, the Lady of Provence," and the "Switzer's Wife,") unsullied by any grosser alloy of mean ambition. Her religion, too, is essentially womanly, fervent, clinging to belief, and, "hoping on, hoping ever," in spite of the peculiar trials appointed to her sex, so exquisitely described in the "Evening Prayer in a Girl's School:"—

— Silent tears to weep,  
And patient smiles to wear through suffering's hour  
And sunless riches from affection's deep  
To pour on broken beds—a wasted shower!  
And to make idols, and to find them clay,  
To bewail that worship—

If such was the mind of her works, the manner in which she wrought out her conceptions was equally individual and excellent. Her imagination was rich, chaste, and glowing; those who saw only its published fruits, little guessed at the extent of its variety. But it is possible that we may recur to the subject again, and this is not the time for deliberate and cold criticism.

It is difficult to enumerate the titles of her principal works. Her first childish efforts were published when she was only thirteen, and we can only speak of her subsequent poems—"Wallace," "Dartmoor," "The Restoration of the Works of Art to Italy," and her "Dramatic Scenes," from memory. These were, probably, written in the happiest period of her life, when her mind was rapidly developing itself, and its progress was aided by judicious and intelligent counsellors, among whom may be mentioned Bishop Heber. A favorable notice of one of these poems will be found in Lord Byron's Letters; and the fame of her opening talent had reached Shelley, who addressed a very singular correspondence to her. With respect to the world in general, her name began to be known by the publication of her "Welsh Melodies," of her "Siege of Valencia," and the scattered lyrics which appeared in the *New Monthly Magazine*, then under the direction of Campbell. She had previously contributed a series of prose papers on Foreign Literature, to *Constable's Edinburgh Magazine*, which, with little exception, are the only specimens of that style of writing ever attempted by her. To the "Siege of Valencia," succeeded rapidly, her "Forest Sanctuary," her "Records of Women," (the most successful of her works,) her "Songs of the Affections," (containing, perhaps, her finest poem, "The Spirit's Return,") her National Lyrics and Songs for Music,) most of which have been set to music by her sister, and become popular,) and her "Scenes and Hymns of Life." We have no need to speak critically of any of these; the progress of mind and change of manner which they register have already been adverted to in our columns.—Nor need we do more than repeat our conviction that she had not as yet reached the full strength of her powers. A few words with respect to their direction in later days, may be worthily extracted from a letter of hers, which lies before us. She had been urged by a friend to undertake a prose work, and a series of "Artistic Novels," something after the manner of Tieck, and Goethe's *Kunst-Romanen*, as likely to be congenial to her own tastes and habits of mind, and to prove most acceptable to the public.

"I have now," she says, "passed through the feverish and somewhat visionary state of mind often connected with the passionate duty of art in early life; deep affections and deep sorrows seem to have solemnized my whole being, and I now feel as if bound to higher and holier tasks, which, though I may occasionally lay aside, I could not long wander from without some sense of dereliction. I hope it is no self-delusion, but I cannot help sometimes feeling as if it were my true task to enlarge the sphere of sacred poetry, and extend its influence. When you receive my volume of "Scenes and Hymns," you will see what I mean by enlarging its sphere, though my plan as yet is very imperfectly developed."

Besides the works here enumerated, we should mention her tragedy "The Vespers of Palermo,"

which, though containing many fine thoughts and magnificent bursts of poetry, was hardly fitted for the stage, and the songs which she contributed to Colonel Hodges' "Peninsular Melodies." And we cannot but once more call the attention of our readers to her last lyric, "Dependancy and Aspiration," published in *Blackwood's Magazine* for this month; it is the song of the swan—its sweetest and its last!

In private life, Mrs. Hemans had attached to herself many sincere and steadfast friends. She was remarkable for shrinking from the vulgar honors of *lionism*, with all the quiet delicacy of a gentlewoman; and at a time when she was courted by offers of friendship and service, and homages sent to her from every corner of Great Britain and America, to an extent which it is necessary to have seen to believe, she was never so happy as when she could draw her own small circle round her, and secure in the honest sympathy of its members, give full scope to the powers of conversation which were rarely exerted in general society, and their existence, therefore, hardly suspected. It will surprise many to be told, that she might, at any moment have gained herself a brilliant reputation as a wit, for her use of illustration and language was as happy and quaint, as her fancy was quick and exursive; but she was, wisely for her own peace of mind, anxious rather to conceal than to display her talent. It was this sensitiveness of mind which prevented her even visiting London after her name had become celebrated; and, in fact, she was not seldom reproached by her zealous friends for undervaluing, and refusing to enjoy the honors which were the deserved reward of her high talents, and for shutting herself up, as it were, in a corner, when she ought to have taken her place in the world of society as a leading star.—The few who knew her will long remember her eager child-like affection, and the sincere kindness with which, while she threw herself fully and frankly on their good offices, she adopted their interests as her own for the time being.

One of two traits may be further added to this imperfect sketch, though, as some further reminiscences of our friend may possibly be attempted by the writer of this notice, many things which remain to be said will be deferred to a more fitting time. It may be told, that when young, she was remarkable for personal attractions; that her talents for music and drawing (merely another form of the spirit which was the living principle of her life) were of no common order. Her health had for many years been precarious and delicate; the illness of which she died was long and complicated, but, from the first, its close was foreseen; and we know from those in close connection with her, that her spirit was placid and resolved, and that she looked forward to the approach of the last struggle without a fear. It is consolatory to add, that her dying moments were cheered by the kind offices of zealous and faithful friends: for herself, her departure from this world could only be a happy exchange. There is no fear of her being forgotten: we shall long think of her—

Kindly and gently, but as of one  
For whom 'tis well to be fled and gone;  
As of a bird from a chain unbound,  
As of a wanderer whose home is found;—  
So let it be!

#### SUMMARY.

**RICH ARRIVAL.**—The schr. Creole, arrived yesterday from Tampico, has on board one hundred and seventeen thousand, nine hundred and fifty-nine dollars.

**MORE SPECIE.**—The brig Montilla, arrived yesterday from Carthage, has on board \$48,864. The Mariner, from Metamoras, about \$25,000.

**CHICAGO.**—Arrived from June 27th to July 3d, 10 schooners, 1 sloop, and sundry steamboats, with merchandise and passengers. Cleared, 4 schooners.

[From the *Mohawk Courier* of July 9th.]

OUR VILLAGE, presents its usual scene of activity. Traffic seems to be in a prosperous state. Law and medicine have many dealers—we say nothing of the few they command. Printers' bills are paid and printers' duns regarded—as usual!—But it all goes well enough yet. There is a splendid variety in our manner of life; the rude artillery of blasting rocks, discourses rough music "early and late;" and the confused and continuous din of drills borne on the wings of every breeze,

gives token of the ultimate triumph over those barriers which so long held defiance to the progress of improvement. To this, and the ordinary occupations of our citizens, add the zest furnished by the occasional visits of strangers—the passing of travellers—prognosticated matches—lovers quarrels—hopes deferred—emigrant's movement's—western land speculations—railroad trials—wood cock shooting, (we guess) pigeon killing—assaults and batteries—Dublin riots, and Irish weddings, and you have but a mere summary of the delights of life in Little Falls, and quite a superficial idea of our "borough scenes."

**NAVAL.**—The Navy Commissioners on Friday, visited the Frigate Constitution, and we understand she is ordered to the navy yard for some trifling repairs.

The report of two of our seventy fours being ordered to be got ready for immediate service is, we believe, without foundation.

And it is not true that the 110 gunship on the stocks at Philadelphia, has been ordered to be completed for launching.

The U. S. ship Delaware, Com. Patterson, is expected home in October next.—[Gaz.]

Two bucks were recently found lying dead on John's Island, near Charleston, with their horns inextricably locked. They had probably got themselves in that predicament by a furious encounter. The horns of two bucks, locked in the same way, are preserved in the Beaufort Library, taken from two bucks which were found alive, and killed in the defenceless state in which they had placed themselves.

The Tiger which was seen in Middleboro' woods, and which was afterwards decided to be a Hyena, has been killed, and turns out to be a Peacock.

**THE TOWN OF NEWARK INDICTED.**—We are, (says the Newark Daily), ashamed to say that this enterprising and flourishing town! was indicted at the late Sessions of the County Court for not mending its ways. The street specified in the indictment, we understand is that which leads out of Market street to South Orange. Nearly one half the streets of the town might have been included—beginning with Broad street. Shame upon us!

A bill was also found at the same time against the Morris Canal for neglecting to repair its bridges.

**HEALTH OF THE CITY.**—The interments during the last week, in this city, were 124, in Philadelphia they were 158; and in the corresponding week, in this city last year, they were 208.

**STORM.**—This city and vicinity was visited yesterday afternoon with a rain storm of unusual severity. During the progress of it, Dr. Huddleston's extensive Hotel, known as the Mansion House, situated on Washington Square, was struck with lightning. The electric fluid descended one of the chimneys on the north side of the house, but most fortunately resulted in no serious injury to the building. The shock produced by the clap of thunder which followed was tremendous. There were about one hundred persons in the Mansion House at the time, none of whom were injured.—Troy Whig.]

[From the *Cincinnati Gazette*, July 6th.]

**BALLOON ASCENSION.**—Mr. Clayton made his proposed balloon ascent on Saturday afternoon, July 4. He succeeded in the handsomest manner. After ascending to a great height, and hovering a short time over the city, he took his course in an easterly direction, not quite so much south as on his previous ascent. There was but little wind. The departure was a few minutes before six. At sundown the balloon was still visible, a mere speck in the Eastern horizon.

Mr. Clayton was supplied for a long voyage, and it was his determination to remain up as long as he found it practicable to do so.

A vast concourse of people witnessed the ascent. It is estimated that from 3500 to 4000 were within the enclosure. All departed much gratified, no accident having occurred to mar the general satisfaction.

**P. S.**—We learn by passengers that came yesterday afternoon, in the Detroit, that the balloon passed Maysville, a little to the north, at half past eight o'clock, on Saturday evening.

**FUR COMPANY BOAT BURNED.**—The St. Louis Herald of June 26th, says:

A flat boat belonging to the American Fur Company, of this city, arrived here last evening from

the company's post on the Yellow Stone, distant 3000 miles. She brings the news of the total loss of the company's steamboat Assiniboin, by fire. The Assiniboin was lying aground a little below the Mandan villages, where, on or about the first of June, she took fire in the ladies' cabin, and was entirely consumed. The cargo of the Assiniboin, consisting of buffalo Robes, and valued at 70 to \$80,000, was wholly destroyed.

[From the Boston Atlas.]

**IMPROVED LOCK—NEW INVENTION.**—A newly improved lock is now exhibiting at City Hall, the invention and manufacture of the Messrs. Cambell, leather dealers in Clinton street, and on examination it strikes us as a complete safeguard. It is a small, simple lock, requiring but one key and that without guards; not liable to get out of order, and if the checks are not wanted it can be conveniently used as a common lock. It is called the revolving check lock, and the key that belongs to it would be of no service to any one not understanding the particular combinations of the checks, as indicated by a certain scale of figures; these can be changed every day in the year, so that a man might be daily shown how to unlock it—and it could be so changed in a minute or two that he would be as little able as a stranger.

We understand that the inventors offer a reward of fifty dollars to any one who will unlock it. They intend making one on a similar plan, somewhat more secure, place it upon a trunk, depositing in the trunk \$1000 dollars against any one willing to deposit a similar sum—the condition of the deposit to be that if in the course of a twelvemonth the lock is not opened by the most experienced lock-picker that can be found, the whole sum shall be the property of the inventors; if the lock is opened, they forfeit the entire sum. The key belonging to the lock shall be given up to the person taking the offer, and the Messrs. Cambell will unlock the trunk every day during the year in his presence.

We must confess that this wears a little the aspect of the marvellous—for bolts and bars are so easily cut through by the ingenious, under all the circumstances of silence, secrecy and fear of detection—that it seems to us impossible that any mystery would be devised in the way of a lock, which, many an adroit culprit, with a fair field and no favor and three hundred and sixty-five days and nights before him, could not unriddle. But we give the fact as it was given to us, and the doubting must look for themselves.

**MILTON A. PUNSTER.**—Who would have thought it? Old round-head square-toes, a player upon words—a double intender! And punning in the middle of "Paradise Lost," too—the old quiz!—Turn to your book, gentle reader, and there you will find him describing the feeding of Elijah by the ravens, in these proper words:—

Him thought he by the brook of Cherith stood,  
And saw the ravens with their horny beaks  
Food to Elijah bringing, even and morn;  
Tho' raven-ous, taught to abstain from what they brought.

Nor is this a solitary instance; for, by the help of some inquisitorial pains, we have detected the old gentleman at this curious game in several passages of his great work aforesaid. Thus, in the IXth Book, he makes our mother Eve to say—

Serpent, we might have spared our coming hither  
Fruitless to me, though fruit be here to excess.

In Book Xth is another and an outrageous example of indulgence in the propensity we are illustrating:

—The blasted stars look'd wan,  
And planets, planet-struck, real eclipses  
Then suffer'd.

Were it not for these preceding cases of *flagrans delictum*, we might be willing to suppose that the following passage, which we extract from the XIth Book, had perhaps no punning intent; but, as it is, we can hardly acquit the offender. Mark how applicable is the description, in the second meaning, to a gentleman entering a ball room just as the usual liquid refreshment is in course of being handed round:

—Nor could his eye not ken  
The empire of Negus to his utmost Port.

Reading the passage in this sense, (which will intrude itself) we cannot fail to remark the additional strength given to Negus by the bold figure of personification, as expressed in the personal pronoun.

Who shall venture to say, after this, that Mil-

ton has not made extravagant use of the poetic licence?

**SUNDAY TRAVELLING IN GREAT BRITAIN.**—On the discussion in the House of Commons of the Report of the Great Western Railway Bill, Mr. Miles moved the insertion of a clause to prevent travelling thereon on Sunday. After some discussion, Mr. Roebuck, the member for Dublin, rose and said, he saw no more reason why a poor man should be prevented from travelling on a Sunday, than a rich one.

A few Sundays since he was going a little way out of town, and passing along Piccadilly at twelve o'clock, and therefore in the middle of church-time, he met the Duke of Wellington riding—"Hear, hear!"—further on he observed men and horses employed in watering Hyde Park for the benefit of the fine folks—"Hear!"—at Knightsbridge the soldiers were under arms and exercising—"Hear!"—at Hammersmith Bridge he encountered the Lord Chief Justice on horseback—(Cheers and laughter)—and when he reached Hampton Court at three o'clock, whom should he see there but the right honorable Baronet the member for Tamworth. (Much laughter and cheering.) They had a perfect right to enjoy themselves in this way, but so had the poor when they could do it. The rich could go from place to place on horses and in carriages, but travelling on railroads would be chiefly for the benefit of the poor; and it ought not to be restricted. This clause seemed brought forward rather in a Pharisaical than in a Christian spirit, and he hoped it would be rejected. People meddled too much with the morals of each other; let every man take care of his own goodness, and there would be more virtue in the world, though less outward show.

A curious case has lately occupied the attention of the Court of Sessions. In Scotland it has been the custom, from time immemorial, for barbers to shave the laboring classes on Sunday mornings, between six o'clock and ten, to fit them for the church. A barber's apprentice in Dundee, however, lately refused to shave on Sundays, and was brought before the magistrates to answer to a complaint at the instance of his master for disobedience. The magistrates ordered him to shave.—The case was appealed, and came before Lord Jeffrey, sitting in the Outer House, when his lordship decided that he was not bound by law to shave on Sundays. The master presented a reclaiming note to the second division of the Court, and they have reversed Lord Jeffrey's judgment, and found that the young man is bound to crop beards on the Sunday mornings. Here the question stands at present, but it is likely to reach the House of Lords. Glasgow has long been celebrated for its orthodoxy; and the Incorporation of Barbers of that city have a rule two centuries old, that if any member shall shave on Sunday, he shall be fined.

**BALL IN A MADHOUSE.**—The French certainly carry their treatment of the insane to a far higher pitch of refinement than we do. The idea of giving a ball to the inmates of a lunatic asylum may startle some of our mad doctors; but what think they of the following precedent? On the 7th ult., the female patients of the Salpêtrière were treated to a grand ball. The insane ladies themselves were intrusted with the getting up of the entertainment; they adorned the ball room with festoons, garlands, and devices; and in the midst, they crowned with *immortelles* the bust of Pinel, the liberator of the insane from the old system of cruelty and terror. The dancing, it is said, went off with charming effect; the students, intern and extern, did the honors; and the festivity was kept up to an hour sufficiently advanced for the satisfaction of all the parties—who, to do them justice, were indefatigable in their exertions to please and to be pleased. It should be added, that the gay scene (which was appointed and arranged with the most serious object) has been generally attended with good effects; it served admirably to fix and amuse the minds of the patients; and several who labored under melancholia were much diverted, for the time, from their imaginary woes.—M. Esquirol some years ago, it seems, tried this method with success; but it is to M. Pariset, the physician of the Salpêtrière, that the credit is due of having so happily ventured on its repetition in the present instance.—[Medical Gaz.]

**ADDUBON.**—We have seen at COLMAN'S, a most beautiful print by Turner, of our great Ornithologist. It is an admirable likeness, and most spirit-edly engraved.

**JACKSONVILLE, E. F., June 25.**—*Skirmish with a party of Seminole Indians.*—We have been politely favored with the perusal of the following letter addressed to the Postmaster of this place, and have his permission to publish it. We shall feel under obligations to the author, or any other gentleman who will communicate any additional facts in relation to the transaction:

"*Minneapolis, June 20.*—My Dear Sir—An express has this moment arrived (as the mail is closing) from Capt. Walker, of the Spring Grove Guards, announcing, that yesterday a rencontre took place of the most unhappy and alarming character, near Mr. Samuel Gieger's, in this county, between a party of about thirty Indians and a party of white men, in which three of the latter (Mr. Giles Ellis his son Underhill Ellis, and Mr. George Rawls were severely wounded by shots from the Indian) The circumstances are not fully known, though it is understood that the Indians were detected in killing cattle.

"Capt. Walker has mustered a portion of his command, and gone in pursuit of the Indians.

"Yours in haste, G. HUMPHREYS."

The following list of Cadets will be attached to the Army Register, conformably to a regulation for the government of the Military Academy, requiring the names of the most distinguished Cadets, not exceeding five in each class, to be reported for this purpose at each examination.

#### 1st Class.

- 1 George W. Morrell, of New York.
- 2 Charles H. Bigelow, of Massachusetts.
- 3 John H. Martindale, of New York.
- 4 Charles J. Whiting, of Maine.
- 5 George M. Legate, of Maine.

#### 2d Class.

- 1 Montgomery C. Meigs, of Pennsylvania.
- 2 Alexander Hamilton, of New York.
- 3 George D. Welcker, of Tennessee.
- 4 James L. Mason, of Tennessee.
- 5 Fisher A. Lewis, of Virginia.

#### 3d Class.

- 1 Edwin W. Morgan, of Pennsylvania.
- 2 Henry W. Benham, of Connecticut.
- 3 Alexander B. Dyer, of Missouri.
- 4 John W. Gunnison, of New Hampshire.
- 5 John Bratt, of New York.

#### 4th Class.

- 1 William H. Wright, of North Carolina.
- 2 Alexander H. Dearborn, of New York.
- 3 Stephen H. Campbell, of Vermont.
- 4 P. G. T. Beauregard, of Louisiana.
- 5 John T. Metcalfe, of Mississippi.

[Navy and Army Chron.]

#### OFFICIAL.—[Order No. 38.]

##### Head Quarters of the Army.

Adjutant General's Office,

Washington, July 1st, 1836.

1. Promotions and appointments in the Army, since the publication of Order No. 24, of May 1st, 1835.

#### 1. PROMOTIONS.

##### CORPS OF ENGINEERS.

Brevet Captain Cornelius A. Ogden, First Lieutenant, to be Captain, 15th May 1835, vice Blaney deceased.

Second Lieutenant Thompson S. Brown, to be First Lieutenant, 15th May, 1835, vice Ogden promoted.

Brevet Second Lieutenant, Jonathan G. Bernard, to be second Lieutenant, 15th May, 1835, vice Brown promoted, (brevet, 1st July, 1833.)

##### REGIMENT OF DRAGOONS.

First Lieutenant Philip St. Geo. Cooke, to be Captain, 31st May, 1835, vice Bean resigned.

Second Lieutenant James Allen, to be First Lieutenant, 31st May, 1835, vice Cooke promoted.

Second Lieutenant J. H. K. Burgwin, to be First Lieutenant, 30th June, 1835, vice Davis resigned.

Brevet Second Lieut. Gaines P. Kingsbury, to be Second Lieutenant 31st May 1835, vice Allen promoted, (brevet 1st July, 1832.)

Brevet Second Lieutenant James M. Bowman, to be Second Lieutenant, 30th June, 1835, vice Burgwin, promoted, (brevet 1st July, 1832.)

Brevet Second Lieutenant Asbury Urry, to be Second Lieutenant, 30th June, 1835, vice Watson, resigned, (brevet 1st July, 1832.)

FIRST REGIMENT OF INFANTRY.

Brevet Second Lieutenant Wm. H. Storer, to be Second Lieutenant, 30th June, 1835, vice Williams resigned, (brevet 1st July, 1832.)

THIRD REGIMENT OF INFANTRY.

Second Lieutenant Richard W. Colcock, to be First Lieutenant, 31st May, 1835, vice Harris, resigned.

Brevet Second Lieutenant, James F. Cooper, to be Second Lieutenant, 31st May, 1835, vice Colcock, promoted, (brevet 1st July, 1834.)

SIXTH REGIMENT OF INFANTRY.

Second Lieutenant Francis J. Brooke, to be First Lieutenant, 6th May, 1835, vice Nichols dismissed.

Brevet Second Lieutenant, Geo. H. Griffin, to be Second Lieutenant, 6th May, 1835, vice Brooke promoted, (brevet 1st July, 1832.)

SEVENTH REGIMENT OF INFANTRY.

First Lieutenant Joseph A. Phillips, to be Captain, 4th May, 1835, vice Cross, resigned.

First Lieut. Nicholas Tillinghast, to be Captain, 1st June, 1835, vice Wilkinson, resigned.

Second Lieut. Samuel Kinney, to be First Lieutenant, 4th May, 1835, vice Phillips, promoted.

Second Lieut. Richard H. Ross, to be First Lieutenant, 1st June, 1835, vice Tillinghast, promoted.

Brevet Second Lieut. James G. Reed, to be Second Lieutenant, 4th May, 1835, vice Kinney, promoted, (brevet 1st July, 1834.)

Brevet Second Lieut. Arnold Harris, to be Second Lieutenant, 1st June, 1835, vice Ross, promoted, (brevet 1st July, 1834.)

II. APPOINTMENTS.

STAFF.

Sohn C. Reynolds, to be Assistant Surgeon, 1st May, 1835.

SECOND REGIMENT OF ARTILLERY.

Brevet Second Lieutenant Epaphras Kibby, 1st Artillery, to be Second Lieutenant, 25th January, 1835, vice Chandler, deceased, (brevet first July, 1834.)

Brevet Second Lieutenant Chas. A. Fuller, Third Artillery, to be Second Lieutenant, 28th February, 1835, vice Wilkinson, resigned, (brevet 1st July, 1834.)

Thomas P. Ridgeley, late Lieutenant, Second Artillery, to be Second Lieutenant, 29th May, 1835.

2. The following named Cadets, constituting the 1st Class of 1835, having been adjudged by the academic Staff, at the June examination, competent to perform duty in the Army, the President of the United States has attached them as supernumerary Second Lieutenants, by brevet, to Regiments and Corps respectively, as candidates for commissions therein.

CORPS OF ENGINEERS.

RANK.

1. Cadet George W. Morrell, to be brevet Second Lieutenant, 1st July, 1835.  
2. Cadet Charles H. Bigelow, to be brevet Second Lieutenant, 1st July, 1835.

REGIMENT OF DRAGOONS.

3. Cadet Jno. H. Martindale, to be brevet Second Lieutenant, 1st July, 1835.

25. Cadet Alexander S. Macomb, to be brevet Second Lieutenant, 1st July, 1835.

26. Cadet John H. Hanly, to be brevet Second Lieutenant, 1st July, 1835.

34. Cadet Philip R. Thompson, to be brevet Second Lieutenant, 1st July, 1835.

42. Cadet Jones M. Withers, to be brevet Second Lieutenant, 1st July, 1835.

61. Cadet Benj. S. Rogers, to be brevet Second Lieutenant, 1st July, 1835.

62. Cadet Wm. N. Grier, to be brevet Second Lieutenant, 1st July, 1835.

FIRST REGIMENT OF ARTILLERY.

6. Cadet Alfred Herbert, to be brevet Second Lieutenant, 1st July, 1835.

7. Cadet Arnoldus Brumby, to be brevet Second Lieutenant, 1st July, 1835.

13. Cadet James N. Ellis, to be brevet Second Lieutenant, 1st July, 1835.

21. Cadet George G. Waggaman, to be brevet Second Lieutenant, 1st July, 1835.

SECOND REGIMENT OF ARTILLERY.

4. Cadet Charles J. Whiting, to be brevet Second Lieutenant, 1st July, 1834.

8. Cadet George M. Legate, to be brevet Second Lieutenant, 1st July, 1835.

9. Cadet Horace Brooks, to be brevet Second Lieutenant, 1st July, 1835.

10. Cadet James M. Morgan, to be brevet Second Lieutenant, 1st July, 1835.

12. Cadet Richard Henderson, to be brevet Second Lieutenant, 1st July, 1835.

17. Cadet James H. Stokes, to be brevet Second Lieutenant, 1st July, 1835.

THIRD REGIMENT OF ARTILLERY.

14. Cadet John L. Keais, to be brevet Second Lieutenant, 1st July, 1835.

15. Cadet William S. Brown, to be brevet Second Lieutenant, 1st July, 1835.

19. Cadet George Meade, to be brevet Second Lieutenant, 1st July, 1835.

FOURTH REGIMENT OF ARTILLERY.

8. Cadet Joseph Roberts, to be brevet Second Lieutenant, 1st July, 1835.

11. Cadet Robert M. Renick, to be brevet Second Lieutenant, 1st July, 1835.

18. Cadet Montgomery Blair, to be brevet Second Lieutenant, 1st July, 1835.

FIRST REGIMENT OF INFANTRY.

28. Cadet Peter C. Gaillard, to be brevet Second Lieutenant, 1st July, 1835.

38. Cadet Samuel M. Plummer, to be brevet Second Lieutenant, 1st July, 1835.

39. Cadet John M. Scott, to be brevet Second Lieutenant, 1st July, 1835.

40. Cadet George W. Shaw, to be brevet Second Lieutenant, 1st July, 1835.

SECOND REGIMENT OF INFANTRY.

16. Cadet Henry L. Kendreck, to be brevet Second Lieutenant, 1st July, 1835.

36. Cadet S. T. Tibbatts, to be brevet Second Lieutenant, 1st July, 1835.

44. Cadet John W. Scott, to be brevet Second Lieutenant, 1st July, 1835.

46. Cadet R. M. Patrick, to be brevet Second Lieutenant, 1st July, 1835.

THIRD REGIMENT OF INFANTRY.

29. Cadet Herman Haupt, to be brevet Second Lieutenant, 1st July, 1835.

33. Cadet William S. Henry, to be brevet Second Lieutenant, 1st July, 1835.

41. Cadet Joseph H. Eaton, to be brevet Second Lieutenant, 1st July, 1835.

45. Cadet Larkin Smith, to be brevet Second Lieutenant, 1st July, 1835.

FOURTH REGIMENT OF INFANTRY.

31. Cadet Alexander M. Mitchell, to be brevet Second Lieutenant, 1st July, 1835.

43. Cadet Isaac Reve, to be brevet Second Lieutenant, 1st July, 1835.

FIFTH REGIMENT OF INFANTRY.

23. Cadet Henry M. Naglee, to be brevet Second Lieutenant, 1st July, 1835.

32. Cadet Alexander H. Tappen, to be brevet Second Lieutenant, 1st July, 1835.

35. Cadet W. M. D. McKissack, to be brevet Second Lieutenant, 1st July, 1835.

48. Cadet Joseph H. Whipple, to be brevet Second Lieutenant, 1st July, 1835.

50. Cadet R. A. Wainwright, to be brevet Second Lieutenant, 1st July, 1835.

SIXTH REGIMENT OF INFANTRY.

24. Cadet Archibald Campbell, to be brevet Second Lieutenant, 1st July, 1835.

33. Cadet W. H. De Forest, to be brevet Second Lieutenant, 1st July, 1835.

63. Cadet Thomas T. Brent, to be brevet Second Lieutenant, 1st July, 1835.

SEVENTH REGIMENT OF INFANTRY.

20. Cadet William H. Betts, to be brevet Second Lieutenant, 1st July, 1835.

22. Cadet W. K. Hanson, to be brevet Second Lieutenant, 1st July, 1835.

27. Cadet W. H. Griffin, to be brevet Second Lieutenant, 1st July, 1835.

37. Cadet James M. Wells, to be brevet Second Lieutenant, 1st July, 1835.

47. Cadet Thomas B. Alden, to be brevet Second Lieutenant, 1st July, 1835.

49. Cadet Lucius Bradbury, to be brevet Second Lieutenant, 1st July, 1835.

III. CASUALTIES.

RESIGNATIONS.

Captains.

James Bean, Dragoons, 31st May, 1835.

Truman Cross, 7th Infantry, 4th May, 1835.

N. G. Wilkinson, 7th Infantry, 1st June, 1835.

First Lieutenants.

Jefferson Davis, Dragoons, 30th June, 1835.

Nathaniel S. Harris, 3d Infantry, 31st May, 1835.

Second Lieutenants.

John L. Watson, Dragoons, 30th June, 1835.

Edward R. Williams, 1st Infantry, 30th June, 1835.

Brevet Second Lieutenants.

Abram G. Edwards, Dragoons, 2d May, 1835.

Eustace Robinson, 4th Infantry, 11th June 1835.

DEATH.

Brevet Major George Blaney, Capt. Corps of Engineers, 15th May, 1835.

DISMISSED.

1st Lieutenant John Nichols, 6th Infantry, 6th May, 1835.

3. The officers promoted and appointed will report accordingly, and join their proper stations and companies without delay; those on detached service, or acting under special orders and instructions, will report, by letter, to their respective Colonels.

4. The Brevet Second Lieutenants will join their respective regiments, and report in person for duty, agreeable to regulations, by the 15th day of October; and report immediately, by letter, to their respective Colonels, who will assign them to companies.

By order of ALEXANDER MACOMB,  
Major General Commanding in Chief.  
R. JONES, Adjutant General.

MEMORANDA.

Correction of Dates.

First Lieutenant Joseph D. Searight, 6th Infantry, to rank from 18th April, 1835, vice Richardson, deceased.

Second Lieutenant John Conrad, 6th Infantry, to rank from 18th April, 1835, vice Searight, promoted.

[FOR THE NEW-YORK AMERICAN.]

Musings.—By *Flaccus, in the Country.*

"When my mirth ceases to be instructive, it shall never cease to be innocent."—[ADDISON.]

THE LAMENT OF BACCHUS.

My sun is setting on degraded times,  
My hopes are wreck'd, beyond the power to save;  
For tempests monsters rove these fallen climes,  
And threaten me, Bacchus, with a wat'ry grave.  
Oh! could I weep, my grief would trickle here—  
But no—a foe to water scorns a tear.

For this free land, I left mine eastern home,  
(Freedom with Bacchus ever is allied,)   
For I had heard of old New England rum,  
And for its love the ocean-waves defied;  
And 'mid mint-juleps, slings, and cocktails, here  
Was reigning god for many a jolly year.

Taverns, my temples—bars, my altars shone,  
And high, and low would worship at my shrine;  
The chrysal bottle, then the rich did own,  
The honest jug, poor devil, then was thine—  
Little cared we, old mates for rain or thunder,  
When wine was on the board, and we were under.

Now, all is changed, and water is the cry!  
Canals, presumptuous, course each tavern side,  
And aqueducts, their horrid wash supply,  
'Til Philadelphia splashes with the tide—  
But Gotham baulked all such hydraulic ends,  
For in its councils I had many friends.

Stout worthies they, who saved us that disgrace  
With hydrophobic zeal, for many a year;  
But they are gone—a wishy-washy race  
Of vile aquatics follow in their rear  
Would pour all Croton on us—horrid wish!  
To deluge men with what was meant for fish.

I sink 'neath tempest-venge's most intemperate rage—  
Now Rushon's soda spouts its ceaseless stream—  
Degenerate Niblo truckles to the age,  
And sells ice-cream—ye Gods! what is ice-cream?  
And Willard throws (though truest of the bunch)  
A dash too much of water in his punch.

Oh! Brandy, Whiskey, Arrack, Hollands, Rum!  
Distill'd perfections!—alcoholic graces!  
Ye glorious Wines! your mortal foes have come  
And label'd "poison" on your rosy faces—  
While ye are slandered, can I tamely sit?  
What man of spirit, ever could submit?

Ye are allowed, our sickness to appease,  
If so, then never should we cease to fill,  
For life itself is but one long disease  
And wine the drug for every corporal ill—  
Life is a punch, whatever you profess think—  
Which, of its spirit robb'd, ah! who would drink?

Not Bacchus—death shall sooner end my cares—  
And will, if longer in this watery West—  
My limbs are soaked—my surgeon, too, declares,  
(Terrific thought!) there's water in my chest!  
Farewell, ye streams—rejoice, ye rainy skies!—  
Niagara! roar, for mighty Bacchus flies.

Place me again on Egypt's burning sand,  
From whence I sprang—where springs are ever dry;  
Where rains and dew no more dandle the land,  
And water is unknown—there let me lie—  
There, nobly dying, my last bottle drain,  
And, in the land of spirits, live again!

No. 4.

**LATER FROM FRANCE.**—The following extracts are from papers received by the Courier and Enquirer per Isaac Clason, arrived yesterday from Bordeaux.

**PARIS, June 12.**—The question of intervention is arranged between the powers which are parties to the Quadruple Treaty, and the English journals received yesterday fully confirm what we have written on the subject. A new energy is to be given to the execution of the Treaty. The resources which will be placed at the disposal of General Valdez, will enable him probably to assume the offensive; while the active co-operation of the allies of Queen Isabel II. will give to her government a more energetic action against the factions which oppose her authority.

The English journal the Globe, which is understood to receive official communications from the Ministers, says it is not authorized to announce any particular measure adopted by the government to facilitate the enlistment of English subjects for the service of the Queen of Spain, but that it has strong reasons to believe that the provisions of the foreign enlistment bill will be modified, and that English officers will be permitted to serve as volunteers in the Peninsula without the loss of their half-pay.

**BORDEAUX, June 10.**—We have received by the extraordinary conveyance, news from Lisbon to the 27th of May, which announces an important change in the Ministry. On the 25th the Queen charged the Marquis de Saldanha with the formation of a new ministry, and on the 27th he formed it as follows:

Saldanha, President of the Council and Minister of War; the Duke of Palmella, Minister of Foreign Affairs; Marquis de Loule, Marine; Francisco Antonio de Campos, Finance; Juan de Sousa Pinto de Magalhães, Interior; Manuel Antonio Carvalho, Justice and Worship.

These names, known and honored in the patriotic annals of the country, have been received by the whole population with acclamations of joy.

**LEONORN, May 25.**—Don Miguel is awaking from his lethargy. He left Rome secretly on the 21st, and embarked at Civita Vecchia, on board the steamboat Sully, which arrived here day before yesterday, and left the same day for Genoa and Marseilles. It is said that Don Miguel was seen here habited as a servant, and that the next day he arrived at Genoa in the same dress. There is no doubt but he will go by land to Turin as a servant of some personage. It is probable he will then take the route for Geneva, and proceed to Holland, where he will find a government disposed to aid him.

**NAPLES, May 23.**—For some days past, a great rumbling has been heard in the interior of Vesuvius, and it has not yet ceased.

**MEXICO.**—In addition to the intelligence we published yesterday from this republic, we now lay before our readers, a letter received from Vera Cruz through the Post Office.

VERA CRUZ, June 22d, 1835.

To the Editors of the Courier and Enquirer:

Gentlemen—I avail myself of the departure of the Elbe to inform you that the attack of Santa Anna on the state of Zacatecas, was completely successful. The sovereignty of that state has been destroyed, and it is now in the full enjoyment of all the privileges and immunities of a military government, directed adroitly by the priesthood. The torch of rational liberty is extinguished in the Republic, save in the petty and insignificant state of Chiapas, whose worthy Governor is yet making a manly resistance to the encroachments of arbitrary power. Since the downfall of Zacatecas, all the principal cities and villages of the interior have pronounced for centralism. They have been goaded in to this expression of feeling by the military arm, which acts under the direction of the friars and priesthood. This city has not yet followed the example of her more powerful neighbors; it is thought the citizens want the gentle stimulus of bayonets in order to arouse them to a proper sense of the important advantages that will result to them by destroying the present system of government, and substituting a central government or a monarchy—the latter is the most probable.

The excesses committed by the victor Santa Anna and his troops in Zacatecas and vicinity, are without a parallel in the history of civilized nations. It appears that all strangers were exposed to their diabolical rage: the only American in the place

was basely assassinated in the presence of his wife, who was afterwards stabbed to the heart, stripped of her clothing and thrown exposed into the street. The English residents at the mines were robbed, their property wantonly destroyed, and some murdered and all menaced with extermination. The English Minister has made a peremptory demand for indemnity to his Majesty's subjects for the injuries done to their property, which he will doubtless obtain. We have no Minister at this Court to make a similar demand for the injuries done our citizens, and if made by our late Chargé des Affaires, it would doubtless be unavailing, as in all previous ones. The impropriety with which the authorities of this country have outraged both the persons and property of our citizens, renders them peculiarly obnoxious to future abuse from the authorities during their civil commotions, of which the country has been abundantly prolific for the last ten years.

The immortal, omnipotent Santa Anna, the singular hero of America, the Napoleon of this continent, (all terms of modest praise which the clergy of this country have bestowed on their favorite,) was to have made his triumphal entry yesterday into the capitol; the majesty and splendor of the scene will doubtless have rivalled that of Pompey's into Rome, and eclipsed every thing of the kind on this continent.

**CIRCULAR.** To ENGINEERS and Superintendents of Railroads and Canals.—I am preparing to issue a new edition of my RAILROAD AND CANAL MAP; and being desirous to correct the errors of the first edition, I take the liberty to request the ENGINEER, or SUPERINTENDENT, of every Railroad and Canal in the UNITED STATES, to furnish me at his earliest convenience with a full and precise account of the condition of the railroad under his direction or charge. He is requested to state the length of the road, the number of miles completed, the elevation it surmounts, the radius of its curves, the style of its construction, its average cost per mile, the number, if any, of inclined planes, with stationary engines—in short, every thing which may be of interest to engineers, or others who may be connected with the subject of Railroads and Canals.

To such as comply with the above request, and furnish the desired information previous to the first of August next, a copy of the new edition of the Railroad and Canal Map, will be sent, by mail or otherwise, as may be directed, as soon as completed.

D. K. MINOR.

New-York, June 27, 1835.

#### PARTNER WANTED.

Wanted, a partner in an extensive Printing Establishment. No one need apply who is not a thoroughbred printer, competent to superintend and direct an office in which upwards of 30 persons are employed, and able to furnish \$3000 cash capital. The best of references will be given and required. Letters, with real name, may be addressed to P. P. P., Post Office, New-York, postage paid, and they will be promptly attended to. May-15

#### TO TUNNEL MINERS, DRILLERS, &c.

Wanted, immediately, 50 Tunnel Miners, (Cornish Miners will be preferred,) 50 Drillers, 50 Laborers, and two experienced Mine Blacksmiths, on the New York and Harlem Railroad, about five miles from the City. Liberal wages will be given, and cash payments made every fortnight. Apply at Mr. FOWLER'S, St. John's Hall, Frankfort street, New-York.

JOHN RUTTER, Contractor.

By The Albany Argus, Philadelphia U. S. Gazette and Pennsylvania, will please copy this, and send their bills to the Railroad Company, 14 Wall street, New-York. 23-1f

#### RAILROAD IRON.

500 Tons Railroad Iron, 9 inch by 1, with Spikes and Splicing Plates to match, for sale by

WM. G. BULL & CO. 74 Wall-st. 26-3p

#### RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order car wheels, chairs and knees, and every other description of castings required for railroads. R-1y 16b14

#### PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

Railroad Spikes of every description required, made at the Albany Spike Factory. Spikes made at the above Factory are recommended to the public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to admit water.

Orders may be addressed to Messrs. ERASTUS CORNING & CO., Albany, or to THOMAS TURNER, at the Factory, Troy, N. Y. sept. 18-1y

#### STEPHENSON,

Builder of a superior style of Passenger Cars for Railroads,

No. 264 Elizabeth street, near Bleecker street, New-York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. J26 1f

#### RAILROAD CAR WHEELS AND BOXES, AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS.

Also, Flange Tires turned complete.

J8 ROGERS, KETCHUM & GROSVENOR

#### RAILWAY IRON.

95 tons of 1 inch by 1 inch, Flat Bars in lengths of 200 do. 1 1/2 do. 14 to 15 feet, counter sunk 40 do. 1 1/2 do. holes, ends cut at an angle 300 do. 2 do. of 45 degrees, with splicing 500 do. 3/4 do. plates and nails to suit.

250 do. of Edge Rails of 36 lbs. per yard, with the requisite chairs, keys and pins.

Wrought Iron Rims of 30, 33, and 36 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels.

Axles of 2 1/2, 3, 3 1/2, 4, and 4 1/2 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment. A. & G. RALSTON.

9 South Front street, Philadelphia.

Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them. d11meowr

#### SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by

E. & G. W. BLUNT, 154 Water street, corner of Maiden lane.

J31 6t

#### SURVEYING AND ENGINEERING INSTRUMENTS.

The subscriber manufactures all kinds of Instruments in his profession, warranted equal, if not superior, in principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Goniometer, with two Telescopes—and a Leveling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes.

WM. J. YOUNG,

Mathematical Instrument Maker,

No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested. Baltimore, 1832.

In reply to thy inquiries respecting the instruments manufactured by thee, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish thee the following information. The whole number of Levels now in possession of the department of construction of thy make is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accidents to which all Instruments of the kind are liable.

I have found that thy patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a reversing telescope, in place of the vane sights, leaves the engineer scarcely any thing to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,

JAMES P. STABLER, Sup't of Construction of Baltimore and Ohio Railroad.

Philadelphia, February, 1833.

Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Germanstown, February, 1833.

For a year past I have used Instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these Instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

HENRY B. CAMPBELL, Eng. Philad. Germant. and Norrist. Railroad

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, JULY 25, 1836.

We have received, and in our next shall give some extracts from, the Report of ALEXANDER C. TWining, Esq., who has recently completed the Preliminary Surveys of the route for a Railroad from New-Haven to Hartford, Conn.

We have also on hand, and shall publish in our next, the concise Report of J. M. Fessenden, Esq., of his Preliminary Surveys for a continuation to Springfield, Mass., of the Boston and Worcester Railroad.

**RAILROAD CONVENTION.**—We are gratified to learn, as we do from the last Oneida Whig, that the citizens of Utica are about to send delegates to the Convention at Owego, on the 28th inst. From this, it would appear that the citizens do—if their late representative to the Legislature did not—appreciate the importance of this great work.

**BALTIMORE AND WASHINGTON CITY RAILROAD.**—All who have occasion to pass between the cities of Washington and Baltimore, will rejoice with us to learn that the railroad is completed. Cars have passed both ways each day since the 20th inst. Long may they continue to do so unobstructed.

Bituminous coal has been found in the immediate vicinity of Erie. [Pennsylvanian.]

**NEW-YORK AND ERIE, AND THE SUSQUEHANNAH AND UTICA RAILROADS.**—The following article from the Oneida Whig treats the subject of the New-York and Erie Railroad in a rational and proper manner; and it is to us a matter of deep surprise and mortification, that a similar disposition has not been heretofore manifested by those highly favored towns, cities we might say, along the line of the canal, and the inhabitants in their vicinity, which are to be so greatly benefitted by this railroad and its numerous branches that will connect it with the canal. It would seem that their blindness, or want of discernment, was willful, as we cannot conceive that any person of ordinary intelligence, who would give the subject a thought, could avoid seeing the direct tendency of the work to promote the general, and of course their immediate, interest. Can any person who is familiar with the lay of the country, and the course of its principal water-courses, deny that a branch, leaving Binghamton and following for many miles the Onondaga River, will again branch and connect both with Utica and Syracuse? And is it not equally certain that another branch will reach Geneva and Rochester, thereby opening to the whole country, with very little difficulty, an easy and direct access to New-York at all seasons of the year? These are facts, and they must soon be acknowledged by all.

[From the Oneida Whig of July 14.]

**NEW-YORK AND ERIE, AND UTICA AND SUSQUEHANNAH RAILROADS.**—The first mentioned railroad is to connect the city of New-York with Lake Erie, and is to pass through the counties of New-York, Westchester, Rockland, Orange, Sullivan, Delaware, the southern part of Chenango, Broome, Tioga, Steuben, Allegany, Cattaraugus and Chataugue. Any person, by a glance at the map of this state, will at once discover the extent and importance of this line of communication, the wide field of territory it will open, the new sources of business and enterprise it will create, and the great number of our fellow citizens,

who are immediately interested in its prosecution. The whole south-western, southern and south-eastern tier of counties, are deeply concerned in this splendid undertaking, which they regard as indispensable to their prosperity. Throughout that whole portion of our territory, (containing a very large amount of wealth and population of the state) the public attention is aroused to this subject, and the people, almost as one man, are resolved that no effort shall be spared—no proper means left unemployed, to carry into successful execution an enterprise so essential to them and to the state at large. The spirit thus awakened will never slumber, and the day cannot be remote which will witness the completion of this great line of internal communication.

To their fellow citizens in other and more favored sections of the state, our brethren of the southern counties look, and we think justly, for countenance and aid in this undertaking, which is to open additional channels of enterprise—add greatly to the aggregate wealth and business of the state, and secure to our own citizens a great and growing trade, which our enlightened and ever watchful neighbors are striving to seize from us and appropriate to themselves. In addition to the just claims of our fellow citizens of the counties above referred to, this central section of the state has a deep and immediate interest in the contemplated work.

The Utica and Susquehanna railroad, for which a charter has already been granted, is to connect with the New-York and Erie, at or near Bettsburg, on the line between Chenango and Broome counties, about 70 miles south of Utica—and thus a railroad communication between this city and the city of New-York, as well as the southern and southwestern counties, will be established. The importance to us of such a communication cannot for a moment be doubted. A safe, direct, and speedy communication, at all seasons of the year, with our great commercial metropolis is thus obtained; and completed, (as they assuredly will be,) it is not extravagant to anticipate that the intercourse between New-York and Albany, during the suspension of river navigation, will be by way of Utica. The importance to our own county and city, of these railroads, cannot be too highly estimated. Our extensive woollen and cotton manufactur-

ing establishments on the Sadaqueda and Oriskany, and in other parts of the county; our forges and furnaces, our merchants throughout the county and vicinity, and indeed every class of our citizens engaged in the pursuits of useful and productive industry, have a direct interest in these works, and would feel the beneficent influence of their construction. We ought, then, while yet we may extend to them the aid of our countenance and influence, and give to our fellow citizens of the counties above mentioned assurances, the sincerity and utility of which they shall have no reason to doubt of our earnest desire for their success, of our co-operation in their undertaking. Thus much they expect of us, and would receive from us with feelings of gratification—gratification alike that we were willing to do them justice, and that we were sensible of our own interests. These feelings were fully expressed in a letter which we have seen from a resident of Orange, who is intimately connected with the southern railroad, and much pleasure is manifested at the proposition to send from this vicinity a delegation to their next Convention, which is to be held at Owego on the 29th inst. Our citizens should take this subject into immediate consideration, for we are persuaded that no other can be of more importance to them; and we trust a public meeting will speedily be called, for the purpose of appointing a delegation of respectable and influential citizens to meet our brethren of the southern counties in Convention, to extend to them the "right hand of fellowship," and to co-operate with them in all suitable measures to ensure the consummation of the great work so essential to them, and to us, and so useful, by means of the lateral communication that will be established to every western county.

It may be proper to add, that a large amount of the Utica and Susquehanna stock has already been subscribed for in this city, and that it is determined to commence the work, as soon as it is ascertained that the New-York and Erie Railroad will be constructed as far as Broome county.

[From the London Mechanics' Magazine.]

#### ANCHOR FOR RAILWAY-CARRIAGES ON INCLINED PLANES.

Sir,—Having seen, from several articles in your Journal, that an effectual method of preventing the descent of carriages on an inclined plane, in the event of the chain breaking, is a desideratum, I am induced to forward you a plan for the purpose, which appears to me likely to meet the end in view.

The plan is as follows:

Let a double line of rails be laid down, about 18 inches asunder, and secured firmly in the ground in the middle of the path of the carriage, with holes through them at intervals of a yard; and through these holes let iron bars be put, connecting these new or supplementary lines of rails, so that the rails and bars together may present the appearance of a long iron ladder lying on the ground between the rails on which the carriage runs. Upon these rails a small pair of wheels, about 2 feet in diameter, or less, are to run, connected with the upper end of the carriage by means of two bars, 6 or 7 feet long, which are to hook on and off the carriage. Over the axle of these wheels the draft-chain is to go, to raise it from the ground. The motion of the carriage will, by means of the connecting-bars, always carry these wheels along with it. Another pair of iron bars, reaching within a few inches of these wheels, are then to be hooked or fastened to the same end of

the carriage (but below the other bars), in any simple way that will insure the free descent of their outer ends when unsupported. The outer ends of these bars are to be connected to each other by a strong spring across them, sufficient to bear the sudden check in stopping the descent of the carriage; the draft-chain must go over and be hooked to this spring; and to the under side of the spring is to be fastened a strong hook, which the draft of the chain will keep off the ground, and allow it to pass freely up and down the inclined plane, without touching the cross-bars. If more elasticity is found necessary, than what the cross-spring of the drag-hook will give, the side bars of it connecting it with the carriage may be made with spiral springs, upon the principle of Salter's spring-balance; and the lower these bars are fastened on the carriage, the less quantity of upward pull there will be on the cross-bars and rails to disturb them in their bed.

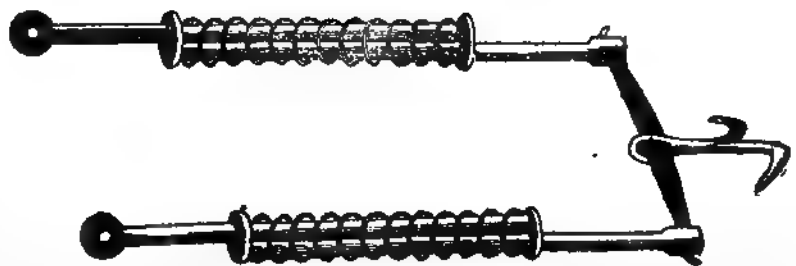

Fig. 1 is a representation of a carriage,

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

provided with such an appendage as I have described, in the act of ascending or descending an inclined plane. The draft-chain is on the stretch, and the drag-hook supported off the ground by the strain of the chain.

Fig. 2 shows the carriage with the draft-chain broken, and the hook anchored on one of the cross-bars, having fallen for want of support from the strain of the chain.

As the draft-chain will not be stretched so tight in transporting carriages down the inclined plane, or drawing empty carriages, as it will in drawing them up, it may be useful to be able to raise the chain somewhat higher than the axle of the small wheels, to compensate for the greater bend of the chain upon those occasions; this can be effected by having a moveable sheave to fix on the middle of the axle, with a deep groove on its circumference, over which the chain is to work, as shown in fig. 3.

Fig. 4 shows the draft-hook, with the

drag-hook under it, the cross-spring and spiral-springs to the side-bars.

It is scarcely necessary to add, that after the carriages have been drawn up or let down the inclined plane, all the bars may be detached, and the rails left clear.

I am, sir, your obedient servant,  
C. PUTLAND.

Dublin, Feb. 14, 1835.

*Experiments on the Transverse Strength and other Properties of Malleable Iron, with Reference to its Uses for Railway Bars.* By PIERRE BARLOW, F. R. S., Cor. Mem. Inst. of France; of the Imp. and Roy. Acad. of Petersburg and Brussels, etc.

(Continued from Number 27.)

*On the Sectional Figure of greatest Resistance, the Area being given.*

Having established the preceding data, I might now proceed directly to find, with a given sectional area, the figure of greatest resistance; but this would be of little advantage, for the form we should arrive at would be quite inapplicable to a railway, as it would require the metal to be principally collected in the lower table; whereas, in the railway bar, we must of necessity bestow a certain quantity, perhaps two-fifths of the whole, in forming the upper table on which the carriage runs; it is, therefore, only after this is provided for, that we are at liberty to dispose of the remaining part of the metal, and even in this distribution regard must still be had to practical convenience. Instead, therefore, of determining mathematically, the area of maximum resistance, the most useful plan will be to compute, directly, the resistance of such sectional figures as fall within the limits of practical application, and to select from them that which, under all considerations, is the best.

The three forms of rails which, under this restriction, will have to be considered, are the following:

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

1. The plain T shaped rail, fig. 1.  
2. The H, or double T, formed rail, with a lower table, as fig. 2.

3. The Trapezoidal rail, as fig. 3. Each of which will admit of various changes of proportions, without altering the general character of the section.

The upper and the lower tables are here represented as rectangular, with sharp edges. In practice these are rounded off, the metal thus displaced furnishing a sort of bracket between the table and stem, or rib, as shown in fig. 4; but to treat of them

in this form would introduce great intricacy into the calculation, without much affecting the results. It will therefore be sufficient to consider them as rectilinear.

I would here observe, also, that some projectors have made the upper and lower tables of equal figure, upon the distant contingency, that when the upper table has been worn down, the rail may be turned, and the lower table made the upper. But this is certainly providing without foresight; for the bottom table is the most efficient for strength, and it would be a very dangerous experiment, after one side of a bar has been submitted for many years to a high compressing force, and its substance (by the hypothesis) greatly worn, to turn the rail, and expose this worn part to a still greater strain, but tensile instead of compressive, which could not fail instantly to destroy it. Instead of this, therefore, I should certainly recommend to work whatever metal is introduced into the lower table or web, into that form which is most efficient for present purposes, without regard to the contingency alluded to above.

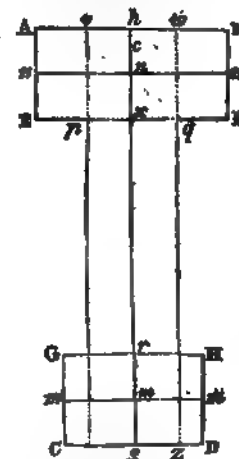

That the rail is deteriorated by exposure and wear, is undoubtedly true; although, perhaps, the amount is not yet well ascertained. Amongst the papers submitted to Messrs. Rastrick and Wood, with whom I was associated, we found it estimated at the rate of  $\frac{1}{4}$ th of a pound per yard per annum; but I have since seen it stated, in a letter from Mr. Dixon to Mr. Bidder, at  $\frac{1}{2}$ th of a pound per yard per annum. This was determined by taking up three rails, having them well cleaned and weighed, and then putting them in their places, and afterwards washing and reweighing them at the end of a twelvemonth, when two of them were found to have lost  $\frac{1}{4}$  lb. in weight for the 5 yards length, and the third  $\frac{3}{4}$  lb., which last was taken up from a particular situation where it was more exposed to friction. But even this does not prove that the whole loss of weight is in the upper face of the rail; and if it did, it would be, as I have before observed, a stronger reason for not turning the rail: and, on the other hand, should the waste not be on the upper surface, the provision alluded to is unnecessary. Mr. Rastrick informs me, that even the small fins left at the meeting of the rolls are still quite distinctly seen on the face of the upper table. And Mr. Stephenson states, that the marks of the tools left in turning the flanches of the wheels are seldom obliterated; which proves, at all events, that there is no side wear.

Mr. George Bidder, who attributes all the waste to the wear on the upper surface, estimates the annual reduction at  $\frac{1}{4}$ th part of an inch; in which case the rails would not last more than thirty years before they would require to be replaced. And it then becomes a question, whether, in point of economy, it would not be better to lay an additional third of an inch upon the upper table, which would, by this reckoning, make the rail last sixty years. This increase of  $\frac{1}{4}$  of an inch would call for an additional expense, to the amount of about  $7\frac{1}{2}$  per cent. on the present cost; and this  $7\frac{1}{2}$  per cent., at compound interest, would amount to about 30 per cent. in thirty years. If, therefore, a charge of 30 per cent. at the end of thirty years, would meet the amount of re-manufacture, and supply the waste, the two accounts would be about balanced. In this case, I must consider the latter as preferable. 1st. Because the other plan would increase the weight of the bar, and the difficulty of the manufacture, and probably diminish its soundness. 2d. Because thirty years' experience may intro-

duce improvements, of which, at the end of that period, it would be desirable to take advantage. And, lastly, because I do not (judging from the opinion of different practical men) think that it has yet been clearly determined what part of the waste is due to wear on the upper face.

To return again to the subject of the best formed section, I beg to repeat, that whatever figure the above, or other considerations, may lead practical men to adopt in the upper or lower table and rib, it will be fully sufficient for the purposes of calculation, to consider them as rectilinear, which will greatly facilitate the investigation, without sensibly affecting the results.

*Comparative Strength of differently-formed Parallel Rails.*

Let A B C D (above figure) represent any rectangular rail with a bottom table;  $n$  its natural axis;  $c$  the centre of compression,  $c$   $n$  being  $\frac{2}{3}$  of  $A$   $n$ . Now, the tension

of each fibre being as its distance from the neutral axis, and that of the lower fibre being given equal to  $t$ , the tension at any variable distance  $x$  will be  $\frac{t x}{d}$  ( $d$  being taken

to denote the whole depth  $n$ ), and therefore the sum of all the tensions will be,  $\int \frac{t x}{d} d x$

$$\frac{t}{d} \int x d x \quad (1)$$

which, therefore, becomes known,  $x$  being taken within its proper limits, according to the figure of the section.

But as the effective resistance of each fibre is also as its depth below the line  $n$ , the sum of all the resistances will be,

$$\int \frac{t x^2}{d} d x \quad (2)$$

$x$  being taken here also within its proper limits. And then to find the centre of tension, or that point into which, if all the tensions were collected, the whole resistance would be the same as in the actual case, this would be given by the formula:

$$\frac{\int x^2 d x}{\int x d x} \quad (3)$$

which is precisely the expression for the centre of oscillation of a disc of the same figure.

We have hence the following general rule for finding the resistance or the weight which any given bar or rail will support at its middle point, within the limits of its elastic power, that is,

Calling the integral of formula (1) = A  
do. do. formula (2) = B  
do. do. formula (3) = C  
And the distance  $c$   $n$  = O

then, referring the sum of all the resistances  $B$  to the common centre of compression, we have,

$$D :: D+C :: B : \frac{B(D+C)}{D}$$

which is the whole effect.

For those who understand the integral calculus, this solution is sufficient, but as the article will probably be consulted principally by practical men, it will be more convenient to give a specific solution for a rail, embracing under one general figure all the usual forms, the only variations being in the depth, breadth, and thickness of the parts. (See preceding figure.)

Let  $A B C D$  represent such a section, of which all the dimensions are given, as also the position of  $n n$  the neutral axis, the point  $c$  which is the centre of compression,  $c n$  being  $\frac{1}{2}$  of  $n h$ , and the point  $m$  which is in the centre of  $r s$ . The breadths  $n n$  and  $m m$  are also known. Then the resistance of the whole section referred to the common centre of compression  $c$ , may be considered to be made up of the three resistances.

1st. Of the middle rib, continued through the head and foot tables,  $v t z w$ .

2d. Of the head  $A E F B$ , minus the breadth of the centre rib.

3d. Of the lower web,  $G C D H$ , also minus the continuation of the centre rib.

Now,  $t$  being taken to represent the tension of iron per square inch, just within its limits of elasticity, we shall have,

1. Resistance of  $v t z w = \frac{1}{2} h s. n s. p q. t$

2. Resistance of  $A E F B = \frac{1}{2} h x. n x. (n n - p q)$

$$\frac{n x}{n s^2}$$

Now, let  $n m + \frac{r s^2}{12 n m} = \delta'$ , and  $\delta' + c n = \delta''$ ,

then

3. Resistance of  $G C D H = n m. r s. (m m - p q)$

$$\frac{\delta''}{\delta'^2}$$

These three resistances being computed, let their sum be called  $s$ , and the clear bearing  $l$ ; then  $\frac{4 s}{l} = w$ , the load the bar ought to

sustain at its middle point, for an indefinite time, without injury to its elasticity.

(To be continued.)

**EFFECTS OF LIGHTNING.**—The Boston Traveller says: Our readers will be interested in the following account of a scientific examination of the several buildings in this vicinity, injured by lightning during the storm of the 13th ult. It is from the pen of a practical electrician, well known in this community, who has been eminently successful in his researches, and who seems at length to have perfected the application of metallic rods to the prevention of dwellings from damage by lightning. It is certainly very remarkable, as mentioned below, that of four buildings struck, three should have been furnished with the round rod so common in most parts of the country.

"SIR—By request of a number of scientific gentlemen, I proceeded in company with one of them to examine the buildings struck by lightning in this vicinity, on the afternoon of Saturday, June 13. The first was the dwelling house of Professor Palfrey, at Cambridge. The Professor politely accompanied us, and

gave us the information required. This building had a round lightning-rod, with points at the top, but blunt in the ground. It was affixed to the back part of the building. In this examination, I was satisfied that the discharge of lightning was horizontal, from one cloud to another, taking the earth in its course. Passing over the points of the rod, it was attracted by them, passed down the rod to the upper part of the lower story; here it left, and struck into the building, passing through various parts and rooms by the bell wires, which were melted and otherwise destroyed. It left the house by the front door. In one remarkable instance, the lightning passed by the side of a door on a bell wire, which it melted, spreading the oxide of the wire on the plastering in its passage.

"From this building we proceeded to Brighton, and examined the meeting-house of the Rev. Mr. Austin. Here I was again satisfied that the discharge of lightning was horizontal; being received on the points of the round rod, it passed down the rod to the side of the building opposite the stove funnel, when it struck into the building, taking the stove funnel in its course, and passed down on one of the supporting pillars of the gallery, and off to the ground on one of the beams that supported the floor.

"Some days after, I visited the meeting-house near the bridge in Braintree, which was struck by lightning during the same storm. This house had also a round rod, pointed at the top and blunt in the ground. Such rods afford but an imperfect protection. In this instance, the earth about the conductor was considerably disturbed. About ten feet from the ground, near the rod, there was a perforation in the side of the building, where the lightning entered and passed under the stairway that leads to the gallery, and through the partition to an iron brace that supported the stove funnel. It then appears to have passed on the funnel to another brace, that was secured to one of the pillars, on which it descended, shattering it to pieces. The pillar opposite was also a little damaged; and other trifling injuries appeared about the building.

"I have also examined a dwelling house at Brookline, that was considerably damaged by lightning at the same time. This house had no conductor. The lightning struck a large tree in front of it, which it evidently left and descended on the building.

"During this thunder storm, we have three instances out of four, where houses having round conductors were struck by lightning, and where, it is evident, the rods afforded but little or no protection. The cause to me is very plain. In the first place, the number of rods is not sufficient. Secondly, they do not present in all directions a sufficient attracting power; and thirdly, they are in most cases put upon buildings by persons who are not familiar with the science of Electricity and the operations of lightning; and who of course are liable to leave them faulty in many very essential particulars."

"During thunder storms, there are three different discharges of lightning—from the earth to the clouds—from the clouds to the earth,—and through the atmosphere from one cloud to another. These latter discharges are more frequent than any other, and often take the earth in their course, and were by the philosophers of the last century called rebounding strokes of lightning. To meet these various discharges of lightning, we must have conductors armed at all parts—that is, they should present in all directions an attracting influence, by which the electric fluid may be discharged gradually and silently, without an explosion. The explosion prevented, all harm is prevented. This attracting, or receiving power, as it is more properly termed, depends on the points; hence the greater the number of points and sharp and rough corners, the greater the protecting power. Conductors should not only be armed with these numerous points, and should be placed upon the most exposed parts of the building. This requires the judgment of a person acquainted with the operations of lightning, and the nature of different substances to conduct it. Let such rods be placed on our buildings, under the direction of an experienced electrician, and we shall no more hear of lightning leaving the rod and striking into the building.

"Certain trifling things have been considered necessary for lightning conductors; such as silvering the points—pieces of glass to prevent the lightning from entering the building—and surrounding the lower extremity of the rod with charcoal. These are of no use whatever. That round rods with their silver points, their glass fastenings, and the lower end surrounded with charcoal, do not afford sufficient protection, is evident from the fact, that a great proportion of the houses struck by lightning are houses professedly protected by such rods. That the square rod with the numerous points and sharp corners does most effectually protect a building, may be easily proved by experiments with an electrical machine, to the satisfaction of every unprejudiced person. Another consideration of some importance in favor of these rods, is the fact, that of more than two thousand houses thus protected, I have never known an instance where the building was in the least injured. These rods discharge the electric fluid without an explosion, and consequently without harm."

**JUNCTION OF THE RHINE AND THE DANUBE.**—Frankfort accounts of the 2d June, state, that "the project so long talked of and so important, of connecting the Danube and the Rhine, begins to assume probability. A company, under the direction of Baron la Flèche de Krudenstein, and supported by the wealthiest bankers of Amsterdam and Germany, is making the necessary examinations and plans. Unless unforeseen accidents, or war—which is not likely—should occur to interrupt this enterprise, there is a good chance for the success of a scheme, tending to unite the Black to the North Sea—through an intervening distance of nearly 1200 miles.

[From the Farmers' Register.]

*On Price—the Causes and Effects of the Fluctuations considered, and the Principles maintained applied to the Present Rage for Speculation.* By THOMAS R. DEW, Professor of Political Economy, &c., in the College of William and Mary.

(Continued.)

*Effect of importation of precious metals, and of a restoration of confidence.*—Now, whilst the importation of the metals from abroad is gradually adding to the circulating medium, and therefore partially relieving, by this means, the pecuniary distresses of the country, the number of exchanges in society occasioned by forced sales will of course have a tendency to diminish, because those sales will become less and less frequent, after the violence of the storm has already prostrated all that could not stand against it. Affairs will soon settle down to this new state of things. Many of the wealthy men of the former epoch find themselves bankrupts at the commencement of the new—others again who could command a little ready cash during the crisis, find they have suddenly become wealthy. From this point, the operations of commerce once more begin to extend themselves. Confidence is gradually restored, and with it the credit system begins to be built up again, and the large accession of money from abroad makes the money market much easier than before. The effect of all this is at first to raise prices gradually, and then more rapidly, as a spirit of speculation is generated. When prices are sinking, the spirit of speculation sinks likewise, because each individual is fearful of purchasing, lest he be injured by a farther fall in prices. The credit system likewise is greatly contracted, because the rapid fall in prices, and the frequent bankruptcies occurring from day to day, destroy the confidence of man in man.

Now a rise in prices is accompanied with effects the reverse of these. 1st, The credit system becomes instantly enlarged. When prices are rising all are on the alert: the energies of man are drawn forth; his hopes, which ever have an undue influence, are thrown into play, and the imagination spreads enchanting schemes and projects before him; he is disposed under those circumstances to rush into business, or to get possession of property, whose enhancement in value from the rising tide of general prosperity, is alone expected to make him wealthy. The borrower now can much more easily get money on loan than before, because general confidence is restored, and the constant rise in prices makes property a good security, which before would have been deemed very inadequate. Buying and selling too, under these circumstances, will generally be on credit more and more extended in proportion to the restoration of confidence. Now the immediate effect of the extension of credit, and the increased velocity given to the circulating medium, is to produce a superabundance of money. For, recollect, I have previously shown that sluggish circulation and the destruction of the credit system generated an extraordinary demand for money, which flowed into the country through the medium of importations. The increased velocity of circulation and the re-establishment of the credit system have just the opposite effect, viz. to increase the apparent amount and the real efficacy of the whole circulating medium. Now, when we reflect that the currency has received immense additions during the money pressure from abroad—that the portions hoarded by individuals are thrown into cir-

ulation as soon as the panic subsides—that the banks which have rode through the storm are beginning to increase their business and push out their paper, and thus add to the circulating medium—that the United States' Bank has recovered from the shock which it sustained by the removal of the deposits, and is consequently enabled to do a more liberal and extended business, thereby enabling other banks to enlarge likewise—we are not to wonder, under these circumstances, that we have a redundant circulating medium; especially, when we recollect that this increased currency is circulating with greatly increased velocity: and the effect of these combined causes must be a vast enhancement of prices, and a consequent rage for speculation. I will exemplify this by a very simple illustration. Let us suppose a particular neighborhood, whose exchanges, in ordinary times, are effected by \$1000. Now I have shown, if any causes operate to make the circulation only one-half as rapid as the ordinary circulation, then the \$1000 will not appear to our little district to be more in amount, or in real efficacy, than \$500. In this state of things, throwing out of view all other causes, prices in the neighborhood supposed would fall to half their former amount. Now, let us farther suppose that this fall in prices should cause an importation of \$500 additional into the neighborhood, and that the rapidity of circulation was again restored, do we not clearly see that we should have a currency redundant by \$500? And this would not only, on the great principle of supply and demand, carry up prices to their former level, but would increase them, in the case supposed, fifty per cent. beyond that level. Now what I have been saying here of a neighborhood, may with equal propriety be said of a whole nation. Let us suppose, for example, the circulating money of this country to be \$100,000,000, in ordinary times; that the circulation becomes suddenly only one-half as rapid as before; then the whole \$100,000,000, even supposing the quantity kept in circulation undiminished, will perform no more exchanges than \$50,000,000 would with the former rate of velocity in the circulation. Prices then would generally sink to half their former amount; money would flow in, let us suppose \$25,000,000; and immediately afterwards, the restoration of confidence, and the consequent re-establishment of the credit system, would communicate to the circulating medium the same velocity as before: you would then have a redundancy of twenty-five millions of dollars, and a consequent rise of prices at least twenty-five per cent. upon the principle of supply and demand alone. But the probability is, prices would rise greatly beyond this point, in consequence of the effect produced by a speculating mania—for when prices are rising, every one wants to purchase. Few are capable of reasoning upon the causes; hence an artificial competition is generated among the buyers, and property rises greatly beyond what it should do, upon the principle of actual supply and efficient demand. The reason of man on these occasions seems to be completely unguided. He looks forward to the realization of wealth by changes in the price of property which he holds in his hands, and almost every one is disposed to turn speculator. And this speculating mania is generally first felt in regard to stocks, whose value is ever fluctuating, and therefore liable to the most sudden impulses, upwards and downwards. I understand at this moment the stock-jobbing spirit to the north has risen to a most extraordinary height. A gentleman, under date of the 28th April,

writes me from Philadelphia, that railroads and canals are the order of the day there—that the papers scarcely find room for politics. He says, "two subscriptions have been opened for canals since I came here. The whole stock for the first was taken in thirty minutes. In the second, the whole stock was taken by the commissioners before the doors were opened. A rush and disappointment followed. Millions could have been taken," &c. All this arises from restored credit; from throwing suddenly the hoarded portions of money into circulation—from increased velocity of circulation—from issue of banks, &c.: all of which have contributed to make currency redundant, prices exorbitant, and the spirit of speculation wild and reckless. When I saw certain politicians congratulating the nation upon fresh arrivals of gold and silver a short time since, I could not but reflect upon the shallow knowledge of political economy which such congratulations proved. The influx of gold and silver was the clearest proof that could be furnished, of the general distress of the country; of the loss of confidence and credit; and of the stagnation of trade and the circulation. The importation of the precious metals could only be effected by parting with a large portion of our wealth; and as soon as a sound currency and circulation could be restored, this newly acquired portion was to be entirely redundant, and even mischievous in its operation, by raising in the community a speculating mania.

*What is to check this rise in prices and spirit of speculation?*—I will now examine into the manner in which this rise in prices is ultimately to be checked, and the spirit for speculation to be cured. And here let me observe, that as there is a certain point of depression below which prices will not go, in consequence of the influx of precious metals which this lowness of prices will certainly produce, so likewise there is a certain point in the elevation of prices beyond which they cannot well go, because of the efflux of the precious metals. It is this efflux which finally checks the speculating mania. I will explain: a rise in prices, when very great, makes our country a good market to sell in, but a very bad one to sell from; hence our imports will greatly overbalance our exports, and a money balance will be created against the nation, which must be paid in money. This produces the exportation of money until the redundancy is sent off; then prices fall, and ruin overtakes the most adventurous in the game of speculation—they involve others, and prices once more sink, from loss of confidence and credit, and stagnation in circulation, below their average level, to be brought up again by the operation of causes already pointed out. Whenever the pendulum of price, (if I may use the expression,) has, either by the operation of the natural course of events, or by the unwise and unskilful tampering of government, been thrown far into one extreme of the arc, it will, in its effort to regain its natural position, go almost so far into the opposite extreme; and the vibrations will frequently last through a long period of time.

*Do these Fluctuations depend entirely upon the Banks?*—Some suppose these fluctuations depend entirely upon the operation of the banking system. This, however, is not the fact. Banks may do a great deal, but are by no means omnipotent in the regulation of a currency. For example; when loss of confidence, stagnation of circulation, and fall of prices, derange the whole credit system, banks are affected like indi-

viduals; they are obliged to curtail their operations and check the further emission of paper, lest a run upon them may break them. They may not under these circumstances have the ability to relieve the distress, however strong the inclination; the relief must come through the wasting process of buying metals from abroad. Again, when prices begin to mount upwards, banks, by issuing upon the favorable moment, may enlarge their issues, and thus swell still farther the already bloated state of the currency. But they cannot prevent, if they be specie-paying banks, the correction of the evil exportation of the metals; for so soon as these are redundant, they will be gathered up for a foreign market; a necessary run will then take place on the banks for the purpose of making the collection, and these banks must either suspend specie payment, curtail their issues, or break. On the first supposition, the evil would have to correct itself by a rise in exchange against us with foreign countries, to the amount of the depreciation caused in the currency by suspension of specie payment. In the second case, prices would be lowered by contraction of the currency from curtailment. In the third, by contraction from the withdrawal of all paper which had emanated from the broken banks, and a loss of confidence in the whole banking system, which would, by the runs made upon them, force all to curtail or break. And thus may we always confidently look forward sooner or later, from causes whose operation I have pointed out, for either a rise in prices when they are very low, or fall when they rise very high. Whenever prices are disturbed, it is a long time before the equilibrium is again restored.

**Effect of Foreign Demand for some of our Agricultural Products on Present Prices.**—So far I have been arguing as if the present state of things were the result solely of that reaction which must sooner or later take place after great depression and stagnation of trade. But the rise in prices may be rapidly accelerated by an extraordinary foreign demand for some of our great staples. Most undoubtedly the rise in the price of cotton has at this moment very great agency in the high prices and rage for speculation, manifesting themselves every where. The price of cotton in this country is regulated by the prices abroad, because the foreign market taking up about four-fifths of the whole product of the United States, it is evident that the value of the article must be determined by the foreign, and not by the home demand. What is the cause of the immense rise which has taken place in the price of cotton within a few months I am unable to say. I am not at this moment in a condition to get at the statistical information required for the investigation of this subject, and my mind not being particularly directed to it, until within a day or two past, I have not noticed from time to time in the papers such articles as might perhaps have given me a clue to the explanation of this interesting phenomenon.

may be the cause, general deficit in the world, or in the Union; or to the rapidly rising cotton fabrics all a spirit of speculation; the gradual reduction to all these causes is, that the price of agricultural staple is well indemnified the end will, if it could be and prosperity over our country.

Let us now examine into the influence exerted by this rapid rise in the price of cotton: and in the first place it is manifest, that the rise in the price of cotton must have had a most important influence on the foreign exchanges. This article alone, constituting a very large portion of the whole of our exports, say two-thirds, a rise in its price has therefore tended to swell the value of our exports, and of course to make money flow more rapidly into the country, through the agency of a favorable balance of trade. From this cause, then, the late money pressure may have lasted a shorter time than it would under other circumstances.

**Influence of the Price of Cotton on the Value of Slaves.**—Again: the rise in the price of cotton has most undoubtedly given an impulse to the price of slaves. Cotton is the great agricultural staple throughout almost the whole of our southern slave-holding states, and consequently the marketable value of slaves will ever be determined by the value of the principal product of their labor. In Virginia and Maryland the price of slaves will always depend upon the external demand, and not on their intrinsic value in those two states.

If the price depended on the real demand arising among themselves, I doubt whether those states could afford to raise them even, so little would be their marketable value.

But there is another cause which I believe at this moment is operating in raising the price of slaves, and will exert a still more powerful influence in future. I mean the late emancipation of the slaves in the British West Indies. That act is certainly indefensible upon every ground of expediency, morality, and religion, but its impolicy appears most glaring when considered in a politico-economical light. Now, whatever may be said about the relative efficacy and value of free and slave labor, there is no question but that free labor, produced by sudden emancipation of slaves, is the most worthless and inefficient labor in the world. Let us take upon this subject the testimony of one who has favored emancipation in the West Indies, and who has already reaped some of the fruits of his folly. Lord Brougham, in his *Colonial Policy*, says, "The free negroes in the West Indies are, (with very few exceptions, chiefly in the Spanish and Portuguese settlements,) equally averse to all sorts of labor which do not contribute to the supply of their immediate and most urgent wants. Improvident and careless of the future, they are not actuated by that principle which inclines more civilized men to equalize their exertions at all times, and to work after the necessities of the day have been procured, in order to make up for the possible deficiencies of the morrow. Nor has their intercourse with the whites taught them to consider any gratification as worth obtaining, which cannot be procured by slight exertion of desultory and capricious industry." The report of the committee of the Privy Council of Great Britain in 1788, of Mr. Braithwaite, the Agent for Barbadoes, and of M. Malouet, who bore a special commission to examine the habits and character of the Maroons in Dutch Guiana, all agree in asserting that free negroes are idle and worthless, and will never provide for the morrow with the foresight of civilized beings. The latter, M. Malouet, says: "Le repos et l'oisivete sont devenues dans leur état social leur unique passion." Does not our own experience in this country prove the truth of his assertion? Do we not find the free negro the pest of the society wherever he is seen? He is the same idle, worth-

less creature in the north as in the south and west of our country. Have not the colonies at Sierra Leone and Liberia most conclusively proven the same fact? Does not the example of St. Domingo, which is now but a wreck of its former self, speak volumes on the same subject? Well, then, with all these facts and evidences before them, what could British statesmen have foreseen from the emancipation of slaves in the West Indies, but idleness and worthlessness of the whole population? and is not this actually the result? Do not all the statements agree in asserting, that the system of apprenticeship has failed to realize the anticipated advantages? and the state of things will be still more deplorable if ever the negro shall obtain his perfect liberty. Now, what will be the consequence of all this? Why, that the British West Indies will soon cease to produce sugar for exportation, and will therefore throw the monopoly of its production into the hands of the slave-holding islands, and of Louisiana and the Floridas in our own country; and this will contribute at once to a rapid rise in slave property.

When St. Domingo was first liberated, the imaginations of more speculative statesmen led them to behold a belt of black republics stretching through the West India Islands, diffusing their moral influence by commerce and social intercourse throughout the habitable globe. Now, what was the fact? Why, that St. Domingo was soon found to have such an idle, worthless population in her newly emancipated blacks, that her commerce was at once destroyed. She has entirely ceased to export sugar, although formerly the most productive sugar growing island in the world. Under these circumstances, to talk of moral influence is perfectly absurd. These black islanders have been, by the effects of their own laziness and vices, as effectually cut off from the rest of the world as if St. Domingo has been enclosed by Bishop Berkeley's forty-foot wall of brass. The London Quarterly Review, in one of its most powerful articles, asserts that nothing but the condition of St. Domingo would have enabled the British West Indies to have borne the oppression of the mother country as long as they did; that St. Domingo being thrown out of the competition in the production of sugar, gave a sort of monopoly to the British islands which enabled them to bear the oppressive regulating legislation of the Parliament. Provided we are let alone by the busy meddling philanthropists, who can attend to every body's business but their own, every negro that gets his liberty in the West Indies, or in South America, will contribute to a rise, upon precisely the same principles, in slave property in our country. The liberation of the slaves in the British West India islands is already producing that effect. If the French, Spaniards, Portuguese, Danes, &c. should be unwise enough to follow this lead, the southern states of our Union will most assuredly reap the benefit; and if Brazil, too, should follow the example, the effect would be almost complete. It would give us a monopoly in both sugar and cotton. Sugar is not made by free labor any where in the world. Even in China, all the sugar and cotton districts are cultivated by slave labor, which in my opinion has not to rest forever, in warm countries, the question about the relative advantages of free and slave labor. The cultivation of sugar requires a great deal of hard labor, which can be expected of the slave alone. In warm countries the principle of idleness triumphs over that of accumulation, and hence slave labor is uni-

versally the most efficient in warm and tropical latitudes. If all the slaves in the West Indies shall ever be liberated, Louisiana will become an *Eldorado*.

*Effect of the Rise of the Price of Cotton and Slaves, on Corn, Wheat, Tobacco, &c.*—The rise in the price of cotton and of slaves is of itself calculated to give an impulse, not only to all the agricultural products of the south, but of the north and west likewise, particularly of the west. Corn, which is the great staple of the middle states, is soon raised in value by high prices for cotton; because all the southern country, which is better adapted to the raising of corn than the middle states, raises cotton exclusively, and thus become purchasers of corn. The cultivation of cotton likewise gradually extends itself even into the middle states, and thus diminishes the quantity of corn raised still farther. In addition to these circumstances, there has been a deficient corn crop for the last two years, in consequence of distressing droughts in the latter part of the season, and too much rain in the commencement. Now, we must recollect that in any necessary of life, like corn, whose price is dependent on the home demand, if a deficit occur, the price will rise generally more than in proportion to the deficit.

The high price of cotton and corn will quickly communicate itself to horses, mules, hogs, cattle, &c., which constitute the great staples of the west; for with corn and cotton high, the middle and southern States will cease in a measure to rear those animals, and consequently will become purchasers. Wheat and tobacco, depending mostly on the foreign market, will not be so much affected. But as ours is the principal tobacco growing country for all Europe, and as an extension of the cultivation of corn and cotton has a tendency to diminish that of tobacco, it is evident that tobacco would be more influenced than wheat by rise in the price of cotton and corn. Accordingly we find that tobacco is now selling very high. The high price of cotton is likewise calculated to make the south a better market for all the products of the north, and to give increased activity to the commercial interest, in which the north possesses the deepest stake. Mr. Lee, the author of the celebrated Boston Report on the Tariff, and one of the best statisticians which this country can boast of, estimated the advantage flowing to the north from the transportation of the cotton of the south, as equal to \$5,000,000 on cotton, amounting in value to \$25,000,000.

*Summary of the Causes of the Present Prices.*—Thus have I rapidly sketched out the causes which have been operating in producing the present prices. In the first place, the late removal of the deposits, and the consequent caution and curtailment of business on the part of the Bank of the United States, together with the unfriendly relations existing between that bank and the state banks, which imposed the necessity of a similar curtailment on the latter, gave a shock to public and private credit, which plunged the country into the greatest distress, and rendered the circulating medium scarce every where, by both diminution of quantity and of the rapidity of circulation. This at once brought down prices to a minimum. The importation of the precious metals from abroad was the immediate consequence of lowness of prices, and tended to relieve the pressure by increasing the currency. By and by, the banks that rode safely through the storm, began when things settled down, to enlarge their business, confidence and credit were restored,

and a redundant circulating medium is the consequence. This of itself is capable of producing high prices, independent of other causes; but in the present instance, it has been aided by the great foreign demand for cotton, which, together with the emancipation of slaves in the British West Indies, has made slaves rise in value throughout our slaveholding country. It has indirectly contributed to the high prices of corn, tobacco, and the staples of the west, and will no doubt, if it continues, diffuse prosperity over all the northern states, in the way I have already explained.

*Prospects.*—In the mean time, let me ask what are our prospects? I answer, that this rise in prices has already excited a rage for speculation, which will, in all probability, carry up prices still higher. A fever for speculation, when once excited in the body politic, always produces, both economically and morally, the most disastrous consequences. It destroys that regular persevering industry by which alone a nation can be enriched. It attracts the capital and resources of the country towards chimerical projects and airy bubbles. During the prevalence of the South Sea scheme in England, hundreds of projects were set on foot, and the sums proposed to be raised by these expedients amounted to more than \$300,000,000, which exceeded the value of all the lands in England. On these occasions, so intoxicated do the people become with a spirit of adventure, that they fall victims to the grossest delusion. Only call it a joint stock company, and thousands of dollars instantly flow into the scheme. All are anxious to enrich themselves by a single stroke of good fortune. The hard-working, plodding man, is looked upon with contempt. Habits of the most luxurious and vicious character are speedily introduced. There is nothing more true than the old adage, "easy come—easy go." A man who makes a fortune at a stroke, is almost sure to spend it extravagantly. He must live high, and give costly entertainments, to purchase the attention and consideration of the new circle into which his wealth has just introduced him. The great merchants, lawyers, physicians, &c. follow the example which is set by the speculators—a reckless, profligate, gambling spirit, is spread through the country—one half the nation is trying to grow wealthy by the ruin of the other half. Every kind of deception, falsehood, and trickery, are resorted to for the purpose of influencing the markets. "During the infatuation produced by this infamous scheme, (South Sea,)" says the historian, "luxury, vice, and profligacy, increased to a shocking degree of extravagance. The adventurers, intoxicated by their imaginary wealth, pampered themselves with the rarest dainties, and the most expensive wines that could be imported; they purchased the most sumptuous furniture, equipage, and apparel, though without taste or discernment; they indulged their criminal passions to the most scandalous excess; their discourse was the language of pride, insolence, and the most ridiculous ostentation; they effected to scoff at religion and morality, and even to set heaven at defiance." A bill was actually brought into the British Parliament for the suppression of blasphemy and profaneness, to so fearful a degree had the spirit of speculation and gambling effected the morals of the people.

The disastrous influence of this rage for speculation in our own country, during 1817, 1818, and part of 1819, was almost as great as that produced in England by the celebrated South Sea bubble, or in France by the Mississippi scheme.

With regard to Virginia, I do not think the mania will be so apt to reach her in its most aggravated form. The high price of negroes and cotton, now producing a fearful emigration to South West, where golden harvests will be realized, if present prices can only be kept up, the spirit for speculation will in a great measure direct itself towards south-western lands. Hence, although corn, wheat, and tobacco, may rise, this exhausting drain of our labor and capital to the south-west, will keep land in this state from rising *pari passu*. Our labor and capital both are swept from our soil as fast as accumulated. At this moment in Virginia, there is a mighty struggle going on between the elastic principle of the black population on the one hand, and the drain to the south-west on the other. And if the high price of slaves shall be kept up for a few more years, I doubt whether all the procreative energies of the race can compensate for the emigration; and in that event we shall be obliged to fill up with Irishmen and northern laborers, or leave the soil of the state comparatively stripped of labor. In the mean time, however, let us preserve our sobriety, our industry, and our morality, enjoying the present advantages of high prices, without rushing into schemes and adventures of a wild and reckless character, under the vain belief that these times are to last forever. Sooner or later, if prices rise above the natural level, they must come down by a process which I have already pointed out. If cotton shall fall speedily, or if a superabundant corn crop shall be made this year, these extravagant prices would be checked at once. And we must recollect, too, that the Bank of the United States is quickly to wind up, and if its curtailment shall be very rapid, it may force the whole banking system of the country to contract its accommodation, and thus, perhaps, to give a shock once more to public confidence. At all events, let us remember the moral of the famous epitaph—"I was well—I wished to be better—and here I am."

May 21, 1835.

FAIR OF THE MECHANICS' INSTITUTE OF THE CITY OF NEW-YORK. — The following circular is cheerfully published with a view of calling attention to the subject.

Institute Rooms, City Hall,  
New-York, July 1, 1835.

This institution was founded in 1830, and incorporated by an act of the Legislature, in 1833, and now enumerates about seven hundred members; and has for its object, the instruction of mechanics and others in all the useful branches of science and the arts, while the tenor and spirit of its construction prohibits the introduction of politics, religion, or irreligion.

The course of education in our common schools, which the young mechanic generally leaves for the workshop, enables him to acquire a knowledge of reading, writing, and the rules of common arithmetic: but beyond these branches it scarcely makes any pretensions: he therefore labors under a serious difficulty at the very commencement of his business, namely, that of being compelled to learn a set of dry and often uninteresting rules, without a previous acquaintance with the principles upon which they are founded. It was with the view of supplying this deficiency, as well as others hereafter to be mentioned, that the 'Mechanics' Institute of the City of New-York' was established. It was designed as a school for teaching the most useful branches of physical and chemical science, to

prepare the mechanic to understand and appreciate the lectures of the college or university, and thus increase his knowledge, usefulness, and happiness. The institution is founded on the most liberal principles, and though intended especially for mechanics, is open to all who are disposed to avail themselves of its privileges. An initiation fee of two dollars and the same amount in annual dues secure admission to its lectures, and exhibitions, and also to the use of the library.

In accomplishing its designs, the Institute has established regular annual courses of lectures on a variety of subjects connected with improvements in the arts, but more especially on chemical and mechanical philosophy. It has also an excellent library, a reading room, museum of models, and a valuable collection of chemical and philosophical apparatus—all of which are appropriated for the benefit of its members. To increase still more the facilities for the acquisition of useful knowledge, the Institute has engaged a scientific gentleman, who, under the supervision of the Board of Directors, has charge of the entire property, and gives his personal attendance at the rooms, which are now kept open day and evening throughout the year.

The Institute Rooms, situated in the City Hall, and consisting of a lecture room, reading room, library, museum of models, apparatus, etc., are now opened daily for the uses of the members and for the inspection of the public, where all who feel an interest in the advancement of science and improvement in the arts, are most cordially invited to call and obtain for themselves more perfect information as to the character, objects, and history of this institution.

To extend still farther its usefulness, and to carry more fully into effect its designs, the Institute has come to the determination to establish an *Annual Fair*, where the results of the genius and industry of the mechanic can find a ready avenue to the public eye, and thus be known and appreciated.

It is not intended that the Fair shall be confined to the productions of our own city; but, on the contrary, it is hoped that its managers may have the gratification of enumerating amongst the articles for exhibition, the productions of mechanical genius from every city and town of the Union.

Under these considerations, the Managers appeal with confidence to the public, and particularly to all immediately interested in the improvement and perfecting of the mechanic arts, to support them in their praiseworthy object—the moral and intellectual elevation of the mechanic, both in his own estimation and in that of others.

It may be further stated, that the Fair will be solely conducted by mechanics, for their improvement and benefit, and that the funds arising from the proceeds will be appropriated for the advancement of the objects of the Institute; it relies, therefore, with the utmost confidence on a liberal patronage from the public generally, and more especially from mechanics.

The Fair will be opened on Tuesday morning, the 29th of September next, at Castle Garden, where all articles for exhibition must be brought on the day previous.

For more detailed information, address the Corresponding Secretary of the Mechanics' Institute, City Hall, New-York.

A circular to the mechanics will soon be issued, containing an account of the pre-

miums to be awarded, and the regulations by which the Fair will be governed.

#### Committee of Arrangements:

Samuel Carter, John Bell, William Ballard, Jonas Lambert, Jr., Henry Durell, John W. Dodd, N. S. Hunt, George Bruce, John Thomas, William Stebbins, Peter Walters, Uzziah Wenman, L. D. Gale, S. S. Ward, William Belcher, William Partridge, Oliver White, G. L. Price, Sereno Newton, Thomas Godwin, J. S. Redfield, W. H. Hale, James Walters, Gabriel Furman, John N. Baur, Daniel A. Robertson, Henry Cunningham, Thomas Timpson, John Steele, Jr., Henry Ludwig, James McBeath, John Remick, G. D. Kashow, George Sullivan, Charles Belcher, John Wint, P. C. Cortelyou, Colin Lightbody, William Norris, Fitch Taylor, Adam Hall, Robert Smith, William Everdell, Alex. Masterton, L. D. Chapin, William Frisby, Walter L. DeGraw, L. Feuchtwanger, Augustus Campbell, Samuel Bailey.

SAMUEL CARTER, Chairman.  
L. D. GALE, Secretary.

#### By order of the Institute:

GEORGE BRUCE, President.

HENRY CUNNINGHAM, Secretary.

✂ Editors who are friendly to the cause here advocated, are requested to use their influence in giving publicity to this circular.

We have been furnished with the following circular, giving notice of the 'Eighth Anniversary Fair, of the American Institute of the City of New-York;' which will, we doubt not, as heretofore, be well attended, and at which our citizens will as usual derive much pleasure.

The Managers have the satisfaction to state, that they have procured for the coming Fair, Niblo's spacious and convenient establishment, 576 Broadway.

Articles intended for competition for premiums, will be received at the Garden on Friday and Saturday, the 16th and 17th of October next.

On Monday forenoon, the 19th of October, the judges will examine the articles intended for premiums. Such as are for exhibition merely, may be brought at any time during the Fair.

On Monday, at 12 o'clock, the Garden and the Saloon will be opened to visitors, and continue open four days.

The preparations for this exhibition already brought to the knowledge of the Managers, satisfy them that the coming Anniversary will afford the most cheering proof of our rapid progress in the arts, by a more ample display of the extent and perfection of American skill and industry, than has ever before been exhibited in this city; as well in the household departments of industry, as in those of the workshops and the larger manufactories.

The objects of the American Institute, under its charter, are broad and multifarious, embracing agriculture, commerce, manufactures, and the arts, throughout the United States. Space has accordingly been provided, suitable for a great number of bulky productions, natural and artificial.

The exhausting effects of our importations of woollens, cottons, and silks, amounting to nearly thirty millions of dollars per annum, render their increased home production extremely desirable. With a view to this, the quantity of broad-cloths presented for competition for the first premium, will be required to be not less than fifty yards; and cassimeres not less than one hundred

yards. And in the awarding of premiums on cotton and silk goods, some regard will also be had to the quantity.

Inventors of curious and useful machines are particularly invited to exhibit their operations. These moving evidences of mechanical genius impart life and entertainment to the scenes.

The Ladies at all our former Fairs have contributed largely to render interesting the display. The Managers rely in full confidence on their continued favors.

Patriotic individuals—friends of American industry, and distinguished characters in this and other states,—are invited to attend the exhibition, and give their accustomed countenance and support to an institution that has for so many years exerted its influence to stimulate industry, and establish on a durable basis the independence of our country.

THADDEUS B. WAKEMAN,  
MARTIN E. THOMPSON,  
ADONIRAM CHANDLER,  
JONATHAN AMORY,  
ANDREW WILLIAMS,  
JAMES F. KENNY,  
JOSEPH TORREY,  
JOHN SAMPSON,  
FREDERICK H. WOLCOTT,  
JOSEPH TITCOMB,  
CHARLES H. HALL,  
ISAAC FRYER,  
EDWARD V. PRICE,  
Managers.

P. S.—In order to give full publicity to the exhibition, Editors of papers friendly to manufactures, the arts, &c., are respectfully requested to give the foregoing one or more insertion.

INDIA RUBBER.—Although so many establishments are in active operation for the manufacture of India rubber, such is the manifest utility of the articles made of it, and such the demand for them by the most intelligent people, that it may be safely said that the whole business is still in its infancy. It is a curious circumstance in the recent history of this novel fabric, that those countries from whence the raw material is drawn, without the least question, must ultimately become the greatest market for India rubber goods in the world. Indeed, tropical climates, of all others, require the clothes and casings which none but New-Englanders seem to understand how to make. The rainy seasons of equatorial regions have been regarded with perfect dread, on account of the utter impossibility of venturing beyond the threshold, without being instantly drenched under those torrents of rain which appear to fall directly from the windows of heaven, and from which no other kind of covering could shield the body. Since the discovery of India rubber cloth, the entire aspect of those deluged countries will be changed. Men may now go abroad for the transaction of business, fearless, though the rains descend in torrents, perfectly comfortable, under the protection of garments so light that the freedom of the body suffers no restraint. One great obstacle to the active operation of armies in the tropical countries has been the periodical rains, destructive alike to soldiers and military armaments. A simple India rubber watch coat and cap completely shuts out the storm, so that nothing short of a flooding of the land could impede the march of soldiery, dressed in these beautifully devised habiliments.

But without all these boundless avenues for the consumption of manufactured India rubber, our own country alone, before the completion of two years more, cannot be

supplied by the united labors of all the manufactories of Boston and its vicinity; hence the value of the corporate property must be constantly increasing; for new conveniences, and unlooked-for contrivances, indispensable even in domestic life, as well as in the useful arts and sciences, are daily being discovered, and which can only be constructed economically from this singular elastic gum. Viewing the progress of discovery, as it especially regards this one article, our admiration is raised, and our wonder excited, by the ingenuity and skill displayed in the various adaptations of India rubber to the daily, and even hourly wants of mankind.—[Scientific Tracts.]

**RAILROAD FROM BRATTLEBOROUGH ON THE CONNECTICUT RIVER TO THE HUDSON.**—A plan is under discussion, for making a railroad from the interior of Vermont, to the Hudson at Troy, and a public meeting was to be held at the latter place on Wednesday evening, to consider of the practicability and means, of accomplishing the project.—There is now a capital M'Adam road making from Troy to Bennington, and this might serve, we should think, also to lay rails on, without interfering with the ordinary travel. Then with a stationary power to pass the Green Mountains, at Bennington, the route might, we should think, be found both practicable, and comparatively cheap, to Brattleborough. Such a road would be of prodigious value to the fine and fertile country thro' which it would pass, and to enterprising and flourishing Troy, where it would terminate.

**BOSTON AND WORCESTER RAILROAD.**—The amount received on this railroad during the last week, for the fare of passengers, was \$3,133 37— for freight \$522 45—total \$3,655 82.

**CANAL TOLLS OF PENNSYLVANIA.**—The whole amount paid into the State Treasury of Pennsylvania, for Canal Tolls, from November, 1834, to July 14, 1835, was \$361,429 88—\$200,000 more than was received during the corresponding season of last year. The Harrisburg Chronicle of Monday says: "The amount yet in the hands of collectors must exceed \$40,000; making the whole sum received on account of tolls from the close of the fiscal year of 1833-34, to the 14th inst., exceed four hundred thousand dollars."

**MAD RIVER AND LAKE ERIE RAILROAD.**—We are pleased to perceive that this improvement, which was sometime since projected, is now in a fair way to be commenced; and we hope, to be vigorously prosecuted to completion. James H. Bell, of New York, has recently been appointed Chief Engineer for the construction of the work. Mr. Bell, we understand, has arrived on the line, and will shortly enter upon the duties assigned him.—[Cleveland Herald.]

**BRIDGE ACROSS THE ILLINOIS RIVER.**—We understand that the stock for erecting a bridge over the Illinois river, (a charter for which was obtained at the last session of the Legislature, with \$50,000 capital, exclusive privileges, has recently been all subscribed, mostly by an eastern gentleman. This bridge is to be located at the mouth of Lake Peoria, and opposite the town of Peoria, and cannot fail to increase greatly the growth and prosperity of that beautiful place.—[St. Louis Bulletin.]

**A MILE A MINUTE.**—A steam car has been built in England, for exportation to the United States, which performed the distance between Manchester and Liverpool at the rate of a mile a minute, (nearly forty miles.) At that rate, when the New York and Erie Railroad is finished, one can breakfast in New York, dine in Buffalo, and be at Detroit, Michigan, the next day, a distance of nearly 800 miles, which is not now travelled in much less than a week.—[Sun.]

AGRICULTURE, &c.

The whole amount of wool raised last year in the United States was seventy-five millions of pounds, in addition to which about three millions were imported from abroad, making the whole quantity manufactured in American factories seventy-eight millions of pounds. In addition to the above, manufactured woollen cloth was imported to the amount of six millions, making the entire consumption in this country eighty-four millions of pounds.—[Baltimore American.]

**THE SILK COCOONERY** of Mr. Samuel Whitmarsh of this town is now in full operation. It is two hundred feet in length and two stories in height.—It is filled with ranges of sliding draws of twine lattice work, upon which the worms feed, and these are intersected by alleys, so that the building has fresh air and light. It is capable of feeding four or five millions of worms. At the present time he has but about eight hundred thousand. He has them in all the various stages, just out of the egg, to the winding the cocoons.

It is curious enough to see the almost invisible little worms just from an egg, less than half the size of a pin head. To notice their expansion each successive day, more than doubling themselves in size, and increasing in a few weeks from the mere mite to the dimensions of a three inch corpulent caterpillar. Then to notice their habits and instinct and way of taking their food, eating in a continued half circle upon the leaf until it is all devoured. Again, the preparation for winding itself up in the cocoon, attaching its two extremities to some object and then throwing out its threads in every direction until it excludes itself from sight.—It thus erects its own tomb and encloses itself within its bosom.

Mr. Whitmarsh does not feed his worms at present upon the Chinese mulberry. The plant is yet rare and the growers are anxious to multiply them, by laying down all the shoots. From the great number under cultivation by various gentlemen in this town, and the care taken to increase them, there is reason to believe the supply will be adequate to all demands next spring. Mr. Whitmarsh has some trees three or four feet in height, which withstood the severity of last winter unharmed. On some of these trees, the berry is now found, and great care will be taken to preserve the seed, so that the precise character of the plant propagated from them may be accurately known.—[Northampton Courier.]

The annual revenues of Prince Esterhazy, in Hungary, are estimated at 2,000,000 silver florins. His debts, or rather those of his father, amount to 18,000,000 florins. His property is at present under sequestration. He possesses about 3,000,000 sheep, whose wool annually produces an immense sum. It is related, that when Prince Esterhazy was Ambassador from Austria to England, he one day heard a young nobleman boasting that he had on his estates 30,000 sheep: "And I," said Prince Esterhazy, "have 30,000 shepherds." This was no exaggeration.

**FLOWER MARKETS.**—These in Paris are held four times each week, during the summer, and form an object of great interest to both strangers and residents. At a reasonably early hour, on market day, may be seen here collected the most choice flowers and most beautiful women, the good taste of the one refined by the delicacy of the other. If such a market were to be instituted here and held beneath the shade of the graceful elms in our Mall, from six to ten o'clock every Saturday morning, our Florists would soon make it attractive to the beaux and belles, and would find a ready sale for their charming productions.—[London paper.]

The Lexington Intelligencer of the 7th inst. says, "We understand that H. CLAY, Esq., sold to Spencer Cooper, Esq., a few days ago, one of the improved short horned Cows, with a calf one day old, by Accommodation, for \$500, but she is said to be unsurpassed in promise. Before the cow and calf were removed from Ashland, Mr. Cooper sold the calf, delivered at weaning, to Major S. Smith, for \$200."

*List of the Forest Trees of America, described in the work of M. Andre F. Michaux. (Concluded.)*

Juniperus virginiana, Red cedar.—Red cedar, only name given to this tree in all parts of the United States where it grows.

Q. Is it not sometimes called *savin*?

Olea americana, Devil wood.—Devil wood, name given to this tree on the Savannah river, in Georgia.

N. B.—We doubt the expediency of establishing this unfashionable name to any tree.

Carpinus ostrya, Iron wood.—Iron wood, only name in all the states to the south of the Hudson. Lever wood, in the district of Maine and Vermont.

Carpinus americana, American hornbeam.—American hornbeam, only name given to this tree throughout the U. States.

We doubt whether it is ever called any thing but simply *hornbeam*.

Hopea tinctoria, Sweet leaves.—Sweet leaves, only name in use in the southern states.

Malus coronaria, Crab apple.—Crab apple, name given to this tree in all the southern states.

Q. Is this a native or indigenous tree?

Mespilus arborea, June berry.—June berry, name given to this tree in the middle states. Wild pear, in the district of Maine.

Magnolia grandiflora, Large magnolia.—Large magnolia, most common name in the cities of the southern states. Big laurel, in the country of the southern states. Laurier tulipier, by the Louisianians.

Magnolia glauca, Small magnolia.—Small magnolia, name given to this tree by many persons in New-York and Philadelphia, as well as in some parts of New-Jersey. Swamp sassafras, secondary name at a given distance from the above cities. Sweet bay, white bay, and swamp laurel, names more used in the southern states. Beaver wood, name formerly given to it in New-Jersey.

Magnolia acuminata, Magnolia cucumber tree.—Cucumber tree, only denomination in all the western states, and along the Allegany mountains.

Magnolia cordata, Heart-leaved magnolia.—The heart-leaved magnolia, name given to this species in Upper Georgia, and which is confounded with the preceding.

Magnolia tripetala, The umbrella tree.—The umbrella tree, only name given to this tree in the middle and southern states.

Magnolia auriculata, The ear-leaved magnolia.—The ear-leaved magnolia. Indian physic, denomination most in use in the mountains of North Carolina and Virginia, but less proper. Long-leaved cucumber tree, second name in the same countries.

Magnolia macrophylla, Large leaved magnolia.—Large-leaved magnolia, name given by M. Michaux to this species, which is confounded with the next preceding one.

Fraxinus americana, White ash.—White ash, only name given to this species in all parts of the United States where it grows.

Fraxinus tomentosa, Red ash.—Red ash, most general name in all the middle states, where this tree is most abundant.

Fraxinus viridis, Green ash.—Green

ash, name given by Michaux to this tree, which has none where it is found.

*Fraxinus quadrangulata*, Blue ash.—Blue ash, only name in Kentucky and Tennessee.

*Fraxinus sambucifolia*, Black ash.—Black ash, most general name in the northern and middle states. Water ash, secondary name in this part of the United States.

*Fraxinus platycarpa*, Carolinian ash.—Carolinian ash, name given by M. Michaux. It has none in the southern states, where he found it.

*Gordonia lasyanthus*, Loblobly bay.—Loblobly bay, only name in the southern states.

*Gordonia pubescens*, Franklinia.—Franklinia, name given by W. Bartram, in honor of Dr. Franklin.

*Cornus florida*, Dogwood.—Dogwood, only name given to this tree in the United States. Bois de fleche batard, by the French of Louisiana.

*Rhododendron maximum*, Swamp laurel.—Swamp laurel, so called on the Alleghany mountains, where this tree is most abundant.

*Kalmia latifolia*, Mountain laurel.—Mountain laurel, most common name in the Alleghany mountains. Sheep laurel, secondary name in the same places. Calico tree, in some parts of the southern states.

N. B.—M. Michaux considers that this plant is not found to the north of the Hudson river. It is abundant in some parts of Massachusetts, where it is generally only a shrub. He says it grows in Carolina to the height of 15 or 20 feet, and as its wood is very hard, it is applied to some useful purposes in the arts.

*Cerasus virginiana*, Wild cherry.—Wild cherry, only name given to this tree throughout the United States.

*Cerasus caroliniana*, Wild orange.—Wild orange, only name given to this tree in the southern states.

*Cerasus borealis*, Red cherry.—Red cherry, name less used than that of small (or dwarf) cherry, but which is more appropriate.

*Annona triloba*, Papau tree.—Papau, only name given to it in the middle and western states.

*Gleditsia triacanthos*, Honey locust.—Honey locust, known under this name only in all parts of the United States where it grows.

N. B.—M. Michaux is mistaken in this general assertion. It is also called three-thorned acacia, in the catalogues of the nursery-men.

*Gleditsia monosperma*, Swamp locust.—Swamp locust, in the maritime parts of the southern states. Water locust, secondary name in the same parts of the southern states.

*Laurus sassafras*, Sassafras.—Sassafras, only name given to this tree in the U. States.

*Laurus carolinensis*, Red bay.—Red bay, only name given to this tree in the maritime parts of the southern states.

*Platanus occidentalis*, Button wood.—Button wood, name generally given in the United States, particularly the Atlantic ones. Plane and sycamore, names more used in the western states. Water beech

name given to it in some parts of Maryland and Virginia. Cottonier, by the French of Upper Louisiana.

*Liquidambar styraciflua*, Sweet gum.—Sweet gum, only name in the United States.

*Lyriodendron tulipifera*, Poplar or tulip tree.—Poplar, general name in the United States. N. B.—This is an evident mistake of M. Michaux. It is seldom called poplar, and it is an improper name to be affixed to it as its popular one. Tulip tree, most common name in the northern states, where it is only known as a cultivated tree. Yellow or white poplar, White wood, name in the Genesee country.

*Bignonia catalpa*, Catalpa tree.—Catalpa tree, general name in the southern states.

*Andromeda arborea*, Sorel tree.—Sorel tree, name given to this tree on the Alleghany Mountains, and in the middle states.

*Celtis occidentalis*, Nettle tree.—Nettle tree, in all the United States.

N. B.—We doubt its having such, or any other name, in the northern states.

*Celtis crassifolia*, Hackberry tree.—Hackberry tree, only name given to it in Kentucky and Tennessee. Hoop ash, upon the borders of the Ohio river, in Pennsylvania and Virginia. Black elder, less common name in the same places.

*Morus rubra*, Red mulberry.—Red mulberry, only name given to this tree in all the United States.

*Pavia lutea*, Buck eye.—Buck eye, only name given to it on the Alleghany Mountains, and in the western states.

M. Michaux ought to have added, that it is also called the yellow-horse chestnut.

*Æculus ohioensis*, Ohio buck eye.—Ohio buck eye, name given by M. Michaux, who claims to have been the first who distinguished it.

N. B.—The popular name of this tree ought also to be either American, or Ohio horse chestnut; for M. Michaux admits it is in truth a horse chestnut, and it would be very embarrassing to admit such confusion in popular names.

*Robinia pseudo-acacia*, Locust tree.—Locust tree, general name in the United States. Yellow locust, red locust, black locust, different names given to this tree on the Susquehannah, having regard to the varied color of the wood.

*Robinia viscosa*, Rose-flowering locust.—Rose-flowering locust, name given by M. Michaux to this tree in the Cherokee country, where it has no peculiar name.

N. B.—It has, however, been called so elsewhere.

*Virgilia lutea*, Yellow wood.—Yellow wood, name given to this tree in Tennessee.

*Ulmus americana*, White elm.—White elm, general name given to this tree, in all parts of the United States where it grows. Michaux.

N. B.—We doubt the generality of this application. It is new to us. It is generally called, in the vicinity of Boston, American elm, or simply elm.

*Ulmus alata*, Wahoo.—Wahoo, name given to this species in the maritime parts of the southern states.

*Ulmus rubra*, Red elm.—Red elm, most common name in all parts of the United States where it grows. Slippery elm, secondary name in New-York and New-Jersey. Moose elm, in the upper parts of New-York. Orme gras, by the Illinois French.

*Planera ulmifolia*, Planer tree.—Planer tree, name given to it to preserve the memory of some individual. Michaux.

N. B.—We are not told who this personage was, nor why the tree (as M. Michaux, in the French idiom, remarks) was consecrated to him.

*Populus tremuloides*, American aspen.—American aspen, name given to this tree in the northern and middle states. Michaux.

N. B.—Sometimes called aspen poplar, and sometimes poplar only.

*Populus grandidentata*, American large aspen.—American large aspen, name given by M. Michaux to this species, which is ordinarily confounded with the preceding one.

*Populus argentea*, Cotton tree.—Cotton tree, known by this name on the Savannah river.

*Populus hudsonica*, American black poplar.—American black poplar, name given by M. Michaux to a species (as he says) before destitute of a name.

*Populus monilifera*, Virginian poplar.—Virginian poplar, name given in Europe to this species.

*Populus canadensis*, Cotton wood.—Cotton wood, name given to this tree on the Mississippi, and the rivers which flow into it.

*Populus angulata*, Carolinian poplar.—Carolinian poplar, name given to it in Europe, because first brought from Carolina.

*Populus balsamifera*, Balsam poplar.—Balsam poplar, known under this name in Canada.

N. B.—It is probable M. Michaux means by this, or the next, the tree which is called black poplar, tacamahac, and balm of Gilead poplar, in the state of Massachusetts.

*Populus candicans*, Heart-leaved balsam poplar.—Heart-leaved balsam poplar.

N. B.—If this is a different species from the last, it is the tacamahac of Massachusetts.

*Tilia americana*, Bass wood.—Bass wood, prevailing name in the north and middle states. Lime, name almost as frequent.

*Tilia alba*, White lime.—White lime, this species on the Ohio is confounded with the last.

*Tilia pubescens*, Downy lime tree.—Downy lime tree, thus called in the southern states.

*Alnus serrulata*, Common alder.—Common alder, in all the United States.

*Alnus glauca*, Black alder.—Black alder, in Vermont.

*Salix ligustrina*, Champlain willow.—Champlain willow, name given by M. Michaux, who found it on Lake Champlain in great plenty.

*Salix nigra*, Black willow.—Black willow, general name in the United States.

*Salix lucida*, Shining willow.—Shining willow, name given by M. Michaux.

NEW-YORK AMERICAN.

JULY 18—24, 1835.

LITERARY NOTICES.

LETTERS DESCRIPTIVE OF THE VIRGINIA SPRINGS, &c. &c., with a map of Virginia. By PEREGRINE PAOLIX. Philadelphia, H. S. TANNER.—All the world hereabouts, that is, such portion of it as has little to do with the labors of the world, is gone or going to the Virginia Springs, which this year bid fair to eclipse our own far famed mineral waters. It is therefore quite *à propos*, that the letters contained in this little volume, and which appeared originally in the U. S. Gazette of Philadelphia, have been collected, corrected, and annotated. Written in a fine vein of humor, and gentlemanly scholarship, and with such a due infusion of the punning propensity, as at once to betray their Philadelphia origin, they are as little like as possible to an ordinary guide book, and yet have all the value of one, so far as imparting information respecting roads, distances, prices, and things to be seen, is concerned. There is, too, a good map of Virginia, whereon the routes of pleasure travellers are carefully laid down. Those bound to the Springs should possess themselves of this little companionable volume, and those who cannot go, and dread hearing too much about them, on the return of the more fortunate travellers who can, may forestall all their raptures by reading and quoting to them, the descriptions here given.

HISTORY OF THE FALL OF THE ROMAN EMPIRE, comprising a view of the invasion and settlement of the Barbarians, by J. C. L. de SISMONDI: 1 vol. 8vo. Philadelphia CAREY, LEA & BLANCHARD.—The name of *Sismondi* as an elegant historian needs not our commendation. The events, which in this volume, have been rapidly, but by no means hastily, treated, exercised and yet exercise a wide influence on Christendom, and the history of them is, as the author so well says, "more than the destruction of ancient civilization, or of the first attempts at the reconstruction of society, according to its modern forms—it is the history of the sufferings of the human race, from the third century of the Christian era, to the close of the tenth."

Little can be added, doubtless, to the results which the laborious research of Gibben has accomplished, in his "Decline and Fall of the Roman Empire," but to many, who have neither the time to study the many volumes which embody that history, nor the means to purchase it, this summary, by such a hand as *Sismondi's*, will be eagerly sought.

SCENES AND CHARACTERS ILLUSTRATING CHRISTIAN TRUTH, No. III. HOME, by the AUTHOR OF "REDWOOD," "HOPE LESLIE, &c. Boston—JAS. MUNROE & Co.—We know not how it happened, that this modest little pamphlet should have been lying some weeks by us, without attracting attention; but so it was, until within a few days, when taking it up accidentally, it was not relinquished, till it was read through—with how frequent swelling of the heart, and how much of emotion that would not be controlled, we are hardly willing to tell. It is the story of a HOME, the humble home of a mechanic, made happy, and blessed, by means within the reach of all—cultivated minds, cheerful dispositions, well-disciplined tempers, integrity of purpose, independence of spirit, and a deep, and abiding, sense of religion. What a privilege is that of such a pen as Miss Sedgewick's, and how admirable the employment of it, to elevate the character, by elevating the aims, and hopes, of the industrious classes of her country men!

DEVOTIONS FOR THE FAMILY AND THE CLOSET, FROM THE MANUAL OF A COUNTRY CLERGYMAN: 1 vol. New York, Protestant Episcopal Press. In prayer we are one, for as the preface of this little book truly states, "the common wants of humanity, bring us all, in private prayer, to a common language." This cannot be other than an acceptable manual, for it is one conceived and executed in earnest and sincere piety, and its petitions and thanksgivings bear the deep and unmistakable impress, of springing from the actual trials and joys of life.

SYNOPTICAL FRENCH GRAMMAR, with a new, short and easy method of learning the verbs—by Prof. J. M. MOULS, N. Y.

This is undoubtedly a work of merit, combining simplicity with accuracy, in a remarkable degree, and thus greatly facilitating to learners, the acquisition of the grammar of the French language. Its tabular form adds to its advantages, by shewing at a glance, the rules and the exceptions applicable to all the cases arising from the various forms of verbs, participles, &c. It would prove a great assistance to teachers, by being hung up in their school rooms, to be readily referred to, on any occasion.

INDIAN SKETCHES, taken during an expedition to the Pawnee tribe, by JOHN T. IRVING, Jr., 2 vols. Philadelphia, CAREY, LEA & BLANCHARD.—Talent, happily—if not estates—may, without violation of law, or republican usages, run on in one family in unbroken succession. Here is another of the *Irving's* who appeals to the public, as an author, and whose appeal will be listened to with pleasure.

These Indian Sketches were made by the writer on the spot, when, in the summer of 1833, he accompanied the United States Commissioner, Mr. Ellsworth (to whom these volumes are dedicated) to the Indians on and near the Platte river—the fierce *Pawnees*, and the fierce, though less numerous *Otoes*.

The readers of the New York American will doubtless remember some admirable descriptions of the council held with these Indians, which appeared in this paper, and which were at the time much copied, and in some instances ascribed to the pen of *Washington Irving*. They were by the author of these volumes—which embody some very striking sketches, most happily traced and carried out.

THE BROTHERS, a tale of the FRONDE; 2 vols: N. Y., HARPER & BROTHERS.—Those, who have been readers of the American Monthly Magazine, since its first establishment, will not have forgotten some scattering chapters under the title of "The Brothers," which, from time to time appeared in its pages, and were perused with breathless interest. We have now the complete work, from which, in anticipation—and perhaps by way of ascertaining their merit—these chapters were taken, and we are sure it will not disappoint expectation, however high-raised.

It is a tale of war, of love, and blood. The Hero is an English cavalier, and who—having unavailingly perilled life and lands in the service of his monarch, in the struggle against the Commonwealth—becomes a soldier of fortune under the noble Condé, in the war, if so it may be called, of the *Fronde*. The Heroine is a creature of love, and holy trust, and high daring—and the incidents are in the court, the cloister, the dungeon, and the battle field. We are not about to spoil any interest in the work, by referring more distinctly to the story; and merely add, that for accurate keeping in the costume of the times, and in portraying the

characters and peculiarities of that period of barbarous crime, and chivalric valor, this tale may claim to rank with those of the author of *Darnley* & *Richelieu*.

SPECIMENS OF THE TABLE TALK OF S. T. COLERIDGE. 1 vol. N. Y., HARPER & BROTHERS.—We referred hastily to this volume last week, and now recur to it, chiefly as introductory to some detached thoughts, taken from its pages, which, tho' falling far short undoubtedly, both in manner and expression, of the same passages as delivered by his glowing lips, may yet convey some idea of his power. Coleridge was a dissertator, rather than talker, and the train once fired, would go on from one illustration to another, through an infinite variety of brilliant, recondite, and sometimes mystical imaginings, which would leave to those around, the part only of admiring, though not always unwearying, listeners.

The specimens that follow are to be taken as selected at hazard, rather than choice.

MARRIAGE.—"You may depend upon it, that a slight contrast in character is very material to happiness in marriage."

STYLE.—"In my judgment Bolingbroke's style is not in any respect equal to that of Cowley or Dryden. Read Algernon Sidney; his style reminds you as little of books as of blackguards.—What a gentleman he was!—Burke's Essay on the Sublime and Beautiful seems to me a poor thing; and what he says upon taste is neither profound nor accurate."

"Painting is the intermediate somewhat between a thought and a thing."

TALENT AND GENIUS.—"Talent, lying in the understanding, is often inherited; genius, being the action of reason and imagination, rarely or never."

SWIFT.—"Swift was *anima Rabelaisii habitans in sicco*—the soul of Rabelais dwelling in a dry place. Yet Swift was rare. Can any thing beat his remark on King William's motto,—*Receptum non rapuit*—that the receiver was as bad as the thief."

DEMOCRACY.—"It has never yet been seen, or clearly announced, that democracy, as such, is no proper element in the constitution of a state. The idea of a state is undoubtedly a government *à république*—an aristocracy.—Democracy is the healthful life-blood which circulates through the veins and arteries, which supports the system, but which ought never to appear externally, and as the mere blood itself."

WOMEN.—"Most women have no character at all," said Pope, and meant it for satire. Shakspeare, who knew man and women much better, saw that it, in fact, was the perfection of woman to be characterless. Every one who wishes a *Desdemona* or *Ophelia* for a wife,—creatures who, though they may not always understand you, do always feel you, and feel with you."

"There are three classes into which all the women past seventy that ever I knew were to be divided: 1st. That dear old soul; 2d. That old woman; 3d. That old witch."

SPURZHEIM.—Spurzheim is a good man, and I like him; but he is dense, and the most ignorant German I ever knew.

CRABBE AND SOUTHEY.—I think Crabbe and Southey are something alike; but Crabbe's poems are founded on observation and real life—Southey's on fancy and books. In facility they are equal, though Crabbe's English is of course not upon a level with Southey's, which is next door to faultless. But in Crabbe there is an absolute defect of the high imagination: he gives me little or no pleasure; yet, no doubt, he has much power of a certain kind, and it is good to cultivate, even at some pains, a catholic taste in literature. I read all sorts of books with some pleasure, except modern sermons and treatises on political economy.

SIR WALTER SCOTT.—Dear Sir Walter Scott and myself were exact, but harmonious opposites in this: that every old ruin, hill, river, or tree, called up in his mind a host of historical or biographical associations, just like a bright pan of brass, when beaten is said to attract the swarming bees—whereas, for myself, notwithstanding Dr. Johnson, I believe I should walk over the plain of Marathon

without taking any more interest in it than any other plain of similar features. Yet I receive as much pleasure in reading the account of the battle, in Herodotus, as any one can. Charles Lamb wrote an essay on a man who lived in past time.—I thought of adding another to it on one who lived not in time at all, past, present, or future—but beside or collaterally. When I am very ill indeed, I can read Scott's novels, and they are almost the only books I can then read. I cannot at such times read the bible; my mind reflects on it, but I can't bear the open page.

**CAREY'S LIBRARY OF CHOICE LITERATURE.**—We refer to an advertisement under this head, by which it will be seen that Messrs. E. L. Carey & Hart, of Philadelphia, are about undertaking a new cheap periodical, to be published weekly, in which it is intended to embody the current literature of Great Britain, and when occasion justifies, translations from the best continental works.

**AN APPEAL FOR THE WEST.**—The article under this head from the Boston Courier, should be read. It is an appeal not addressed to fanatical or sectarian feelings, but to patriotism, and love of well ordered liberty.

**A PLEA FOR THE WEST, BY LYMAN BEECHER, D. D.**—Such is the brief title of a duodecimo volume comprising about 200 pages, which has recently been received here from Cincinnati. A few lines, by way of advertisement, inform the reader that the essay is a discourse, delivered by the writer in several of the Atlantic cities, while on an agency for the Lane Seminary,—and that those who heard it will perceive that it is as it was delivered, with a little enlargement on a few points, which demanded a more ample illustration.

The object of the agency, in which Dr. Beecher was employed in 1834, was to procure funds for the endowment of certain professorships in the Seminary over which he presides. The circumstances of the case are stated in a very few pages at the beginning of the discourse, in a manner most powerful, and peculiarly his own. We do not mean to dwell long on this topic, but there are a few sentences which we cannot refrain from copying.

"No opinion is more false and fatal than that mediocrity of talent and learning will suffice for the West. That if a minister is a good sort of a man, but somehow does not seem to be popular, and find employment, he had better go to the West. No; let him stay at home; and if among the urgent demands for ministerial labor here, he cannot find employment, let him conclude that he has mistaken his profession.

"But let him not go to the West. The men who, somehow, do not succeed at the East, are the very men who will succeed still less at the West. If there be in the new settlements at the West a lack of schools and educated mind, there is no lack of shrewd and vigorous mind; and if they are not deep read in Latin and Greek, they are well read in men and things. On their vast rivers they go every where, and see every body, and judge with the tact of perspicacious common sense. They are disciplined to resolution and mental vigor by toils, and perils, and enterprises; and often they are called to attend as umpires to the earnest discussions of their most able and eloquent men, which cannot fail to throw prosing dullness in the ministry to a hopeless distance. No where, if a minister is deficient, will he be more sure to be 'weighed in the balance and found wanting.' On the contrary, there is not a place on earth where piety, and talent, and learning, and argument, and popular eloquence are more highly appreciated, or rewarded with a more frank and enthusiastic admiration. There are chords in the heart of the West which vibrate to the touch of genius, and to the power of argumentative eloquence, with a sensibility and enthusiasm no where surpassed. A hundred ministers of cultivated mind and popular eloquence might find settlement in an hundred places, and without the aid of missions, and only to increase the demand for an hundred more."

Again:—

"But what will become of the West, if her prosperity rushes up to such a majesty of power, while those great institutions linger which are necessary to form the mind, and the conscience, and the heart of that vast world. It must not be per-

mitted. And yet what is done must be done quickly; for population will not wait, and commerce will not cast anchor, and manufactures will not shut off the steam nor shut down the gate, and agriculture, pushed by millions of freemen on their fertile soil, will not withhold her corrupting abundance.

"We must educate! We must educate! or we must perish by our own prosperity. If we do not, short from the cradle to the grave will be our race. If in our haste to be rich and mighty, we outrun our literary and religious institutions, they will never overtake us; or only come up after the battle of liberty is fought and lost, as spoils to grace the victory, and as resources of inexorable despotism for the perpetuity of our bondage. And let no man at the East quiet himself, and dream of liberty, whatever may become of the west. Our alliance of blood, and political institutions, and common interests, is such, that we cannot stand aloof in the hour of her calamity, should it ever come. Her destiny is our destiny; and the day that her gallant ship goes down, our little boat sinks in the vortex!"

And again:—

"I would add, as a motive to immediate action, that if we do fail in our great experiment of self-government, our destruction will be as signal as the birth-right abandoned, the mercies abused and the provocation offered to beneficent Heaven.—The descent of desolation will correspond with the past elevation. No punishments of heaven are so severe as those for mercies abused; and no instrumentality employed in their infliction is so dreadful as the wrath of man. No spasms are like the spasms of expiring liberty, and no wailings such as her convulsions extort. It took Rome three hundred years to die; and our death, if we perish, will be as much more terrific as our intelligence and free institutions have given to us more bone, and sinew, and vitality. May God hide me from the day when the dying agonies of my country shall begin!"

But it is not on account of the pecuniary wants set forth in this discourse, that we wish chiefly to arrest the attention of the public. It is indeed a Plea for the West, but it might, with equal propriety, be called a Plea for the Republic. We have never read a more powerful display of the dangers to which our government and all our civil, literary, and religious institutions are exposed, nor a more eloquent appeal to the good sense and the patriotism of the people. We know that a great portion of our citizens, immersed in the calls of business or occupied with the consideration of political matters of more immediate and personal concern, view the subject treated of by Dr. Beecher with almost total indifference; and we know that there are many persons who look upon his notions as the bitter ravings of sectarian ambition and prejudice. Let all such persons read the argument,—the unanswerable argument, in our humble opinion,—and we think they will not be disposed to treat the subject with contempt, or the author of the book with a sneer. Dr. Beecher has been accused of endeavoring to stir up the feelings of certain religious sects against the Catholics, and the controversy between him and them has been represented as one of a religious, or sectarian, character merely. We give him credit for purer motives. Let us take his own explanation:

"If, upon examination, it should appear that three-fourths of the foreign emigrants whose accumulating tide is rolling in upon us, are, through the medium of their religion and priesthood, as entirely accessible to the control of the potentates of Europe as if they were an army of soldiers, enlisted and officered, and spreading over the land; then, indeed, should we have just occasion to apprehend danger to our liberties. It would be the union of church and state in the midst of us. The church and the state both in Europe, and the plant colonial church here. Her priesthood, educated under the despotic governments of Catholic Europe, and dependent for their office, support, and honors upon a foreign temporal prince, on whose sanction to their laws and doings they are as dependent as the colonies were upon George the Third; and this prince, too, elected by Austrian influence and sustained by Austrian bayonets, and of course subservient to Austrian policy; a priesthood not elected by their people, or dependent on them during good behaviour, or accountable to them for their deeds, but dependent on a foreign jurisdiction, and to a great extent on foreign patronage. This

would, indeed, be a church and state union—another nation within a nation—the Greek in the midst of Troy.

"Before I proceed, to prevent misapprehension, I would say that I have no fear of the Catholics, considered simply as a religious denomination, and unallied to the church and state establishments of the European governments hostile to republican institutions.

"Let the Catholics mingle with us as Americans and come with their children under the full action of our common schools and republican institutions, and the various powers of assimilation, and we are prepared cheerfully to abide the consequences. If in these circumstances the Protestant religion cannot stand before the Catholic, let it go down, and we will sound no alarm, and ask no aid, and make no complaint. It is no ecclesiastical quarrel to which we would call the attention of the American nation.

"Nor would I consent that the civil and religious rights of the Catholics should be abridged or violated. As naturalized citizens, to all that we enjoy we bid them welcome, and we would have their property and rights protected with the same impartiality and efficacy that the property and rights of every other denomination are protected; and we should abhor the interposition of lawless violence to injure the property or control the rights of Catholics as vehemently as if it were directed against Protestants and their religion. For when the day comes that lawless force prevails argument and free inquiry are ended, and law and courts are impotent and useless, and liberty is extinct, and anarchy by its terrors will compel men to call in the protection of despotic power to save them from the pursuing hell. The late violence done to Catholic property at Charlestown is regarded with regret and abhorrence by Protestants and patriots throughout the land, though the excitement which produced it had no relation whatever to religious opinions, and no connection with any religious denomination of Christians.

"We are equally opposed to any attempt to cast odium upon Catholics of the present generation for any maxims, doctrines or practices of the past ages, which are now by the competent authority of the pope or a general council disavowed. But for all the political bearings of their unchangeable and infallible creed, and for all the deeds of persecution and blood justified by their principles and perpetuated by Catholic powers and not disavowed by his holiness or by a council, the Catholic church is accountable, whatever may be the personal opinion of particular individuals or particular departments of that great community."

"It is to the political claims and character of the Catholic religion, and its church and state alliance with the political and ecclesiastical governments of Europe hostile to liberty, and the tendency upon our republican institutions of flooding the nation suddenly with emigrants of this description, on whom for many years European influence may be exerted with such ease, and certainty, and power, that we call the attention of the people of this nation. Did the Catholics regard themselves only as one of many denominations of Christians, entitled only to equal rights and privileges, there would be no such cause for apprehension while they peaceably sustained themselves by their own arguments and well doing. But if Catholics are taught to believe that their Church is the only church of Christ, out of whose inclosure none can be saved,—that none may read the Bible but by permission of the priesthood, and no one be permitted to understand it and worship God according to the dictates of his own conscience,—that hereby is a capital offence not to be tolerated, but punished by the civil power with disfranchisement, death and confiscation of goods,—that the pope and the councils of the church are infallible, and her rights of ecclesiastical jurisdiction universal and as far as possible and expedient may be of right, and ought to be as a matter of duty, enforced by the civil power,—that to the pope belongs the right of interference with the political concerns of nations, enforced by his authority over the consciences of Catholics, and his power to corroborate or cancel their oath of allegiance, and to sway them to obedience or insurrection by the power of life or death eternal; if such, I say, are the maxims avowed by her pontiffs, sanctioned by her councils, stereotyped on her ancient records, advocated by her most approved divines;

thors, illustrated in all ages by her history, and still UNREPEALED and still acted upon in the armed prohibition of free inquiry and religious liberty, and the punishment of heresy wherever her power remains unbroken: if these things are so, is it invidious and is it superfluous to call the attention of the nation to the bearing of such a denomination upon our civil and religious institutions and equal rights? It is the right of SELF-PRESERVATION, and the denial of it is TREASON or the INFATUATION OF FOLLY."

We believe there is no man, having the ordinary intellectual capacities of man, and exercising the ordinary power of reflection, who will not feel the force of the conclusions to which the writer arrives. Let those who have witnessed the operations of the priesthood in the city of New York, during the last two years, and who have seen similar operations, but on a smaller scale, in other cities, say whether they do not, with Dr. Beecher, feel that "there is no despotism so terrible as a popular despotism under the names and forms of liberty, where ignorance and prejudice, and passion, and irreligion, and crime are wielded by desperate political ambition and a corrupting foreign influence," and whether they do not agree with him, that "if ever our liberties perish, it will be by an explosion of the volcanic power of the European and American populace, and foreign influence and American demagogues in bad alliance, who will ride on the whirlwind and direct the storm."

Excerpts from Com. Porter's Letters from Constantinople.

**MACKEREL IN THE BOSPHORUS.**—"This is the season [Feb. 12] for catching mackerel here. They come down from the Black Sea in immense shoals; and thousands, ay, tens of thousands of boats come at the same moment into the Bosphorus, employed in taking them in seines and gill nets. The quantity taken and sold every day would appear incredible. They are from five to six inches in length, and nothing can be more delicate than they are. By the time they arrive at Gibraltar they are half grown, and full grown when they arrive on the coast of America, three or four months hence.

"The Black Sea appears to be the great nursery for the mackerel, as well as the Palemedes, as they are called here, or the tunny-fish, as they are called when full grown, and caught on the coast of Sicily, Italy, and Spain. Myriads of them are taken during the few weeks of their running. They are generally from a foot to eighteen inches long, and an excellent kind of fish for boiling. Indeed there is no place so abundant in fish as the Bosphorus, and there is no place where there are so many taken. From the windows and doors of most of the houses situated on this beautiful canal they take fish with lines; and in the fine, calm, and beautiful summer mornings, the bay of Buyueder may be seen swarming with kaïcks filled with the ladies and gentlemen of the legation, and with those of the Frank families, and Americans, and Greeks, engaged in the diversion of fishing. It, in fact, makes one of the few, and principal, of the amusements of the country.

"The large fishing boats which are employed for taking the mackerel and the palemedes are generally fifty feet in length, narrow and sharp at both ends, and are of the best construction for velocity. They are rowed by eighteen active young Greeks, who make them fly through the water; and there can be no scene more animating than to see half a dozen of those boats approach the quay, on their return from their fishing excursions, laden with the fish which they have taken at a single haul of their seines. They pull with a strength, quickness, and regularity, which is truly surprising, and the stroke of their oars in the water produces a most singular noise, which may be heard for more than a mile."

**THE TURKISH SHIP MAHMOUD.**—"I visited every part of the ship. The carpenter's work, and the materials of which she is composed, are not equal to those of our ships, but when I say we have not a ship in our service, whose ornamental parts, equipments, and outfit are at all to be compared to those of the Mahmoud, as regards richness, elegance, utility, and expense, I say no more than the truth. Her batteries will consist of one hundred and forty guns, of calibre from five hundred pounds downward. On her main deck she is to carry four of this description, the rest are to be forty-two pounders. Every gun on board is as bright as burnished gold; her gun carriages are absolutely cabinet work; all the iron work about

them is like polished steel, and the brass work, of which there is much, corresponding therewith. The beautiful polish of the rich and costly woods of which the ceiling, sides, and bulkheads of her cabin are composed, strikes the eye with a dazzling magnificence. The floors are covered with the same woods laid in a kind of Mosaic. All the rest of her equipments, which are in a high state of forwardness in the storehouses, are in the same keeping; and when all are put together, and the Mahmoud is complete, the Turks will have it in their power to boast of the largest and most splendid ship in the world."

"Nothing can look more majestic and beautiful than the fleet of the Sultan. I have never in my life seen a fleet of ships of war look so well; they are all fresh painted, and painted in perfect uniformity, that is to say all alike. The Mahmoud is the most splendid ship in the world as well as the largest. She mounts no less than 156 guns, and her dimensions are every way larger than those of our large ship, the Pennsylvania. Nothing can exceed the beauty and magnificence of her internal arrangements, no cost or pains have been spared on them. The Capudan Pacha is a fine young man, a great favorite of the Sultan, and is allowed to do what he pleases. He has much taste, and displays it to great advantage. The cabins are finished off with the most precious woods; all her guns are brass, polished as bright as burnished gold, and the gun carriages looked as if they had come from the hands of the cabinet maker. The stanchions, fore and aft on her decks, are also turned and polished brass. All the rest of the fleet is in equally fine condition, not so splendid to be sure as the Mahmoud, but in beautiful, and, to all appearance, efficient order. What their discipline will be is to be seen hereafter; but I think it promises to be good. The crews are all young and active; apparently perfectly willing and pleased with the service; they are all Turks, and dressed as I believe I before observed, in the same uniform as the soldiers. I went through some of the workshops, boat houses, and stores of the arsenal yesterday, and I do assure you that every thing there is subjected to the most perfect order and arrangement. The boats for the use of the admiralty are magnificent, and the new ones building for the Sultan cannot be described."

#### SUMMARY.

**CRITICS WILL DISAGREE.**—We annex two very different opinions, from respectable papers, on the merit of the *Monikins*. The Baltimore American says:

To use a phrase that is not often set up in type, these volumes will, we think, astonish the natives. In some of his former works, Mr. Cooper has given evidence of a strong infusion of the satirical in his mental composition. In this he lets it have free and full play. It is an elaborate satire. There is much to admire in the work itself: it is no common production, though there is in it much necessarily that is common place. We honor the author for having written and published it.

*Per contra*, hear the Southern Patriot, printed in Charleston:

**THE MONIKINS.**—This is a political satire, as well as a satire on things and matters in general, in the form of an Allegory. We do not think Mr. Cooper at all successful in the category of fiction. His taste and judgment seem sadly at fault, in thus attempting to bring to his powers of ridicule the aid of his imagination. If Mr. Cooper had not given higher evidence of his inventive genius, he never would have taken rank among the most gifted of the writers of prose fiction. The scheme of his satirical allegory wants propriety and truth—it wants congruity and grace. There is nothing to attract the imagination, or to win the sympathy of the reader, by figuring human nature under the degrading imagery of Monkeys.

**PRESIDENTIAL APPOINTMENT.**—We understand that E. A. Brown, of Ohio, late Minister to Brazil, has been appointed Commissioner of the General Land Office, in the place of Elijah Hayward, Esq., resigned.—[Cincinnati Gaz.]

The Pittsburg Statesman, of Wednesday, says: "Our rivers are low, and the business will have to be transferred to the smaller class of steamboats during the dry season. The canal is in fine condition, and the business still good."

**MR. CLAYTON'S BALLOON ASCENT.**—This adventurous Aeronaut, who left Cincinnati on the 4th inst. in his balloon, returned to that city on the 9th. The following is his description of the voyage, as copied from the Cincinnati Evening Post.

At a quarter before six, P. M., (July 4th) I cast off the last rope that secured my Aerial bark to the earth, and immediately she rose majestically into the atmosphere. In an instant I beheld the thousands of spectators that had collected on the outside of the amphitheatre, and in a few moments a rich panorama of Cincinnati and its surrounding country opened to my view.

How delightful was now my situation! High in the air I was suspended by materials capable of bearing twenty or thirty times my weight, and knowing this, I felt as safe as if I had been standing on a firm rock, with bulwarks around me. Beneath me I could view the "Queen of the West," Newport and Covington, and towns, villages, and green and fertile fields. My view was more extensive than some might imagine. I could see objects in every direction, distinctly, 20 miles at least; consequently the area of my scene was more than twelve hundred square miles. Around this view several dense clouds floated, their upper surface was illuminated by the rays of the sun, and they appeared like vast fields, mountains, projecting rocks and caverns, all clothed in pure white.

On leaving Cincinnati, I passed in an East South East direction, and was on the Kentucky side of the Ohio river for a short time, but soon crossed the river again and moved about East by South. At half after six o'clock I lost sight of the Amphitheatre. Thirty-five minutes after six heard the firing of a gun. Ten minutes after seven could hear the people shouting, and heard the firing of cannon three times in succession which seemed at considerable distance.

At seven I took the first observation with the instrument for ascertaining the rate of my travelling, and found that I was moving at the rate of one mile in 4 minutes and 17 seconds—or about 14 miles per hour. The above mentioned instrument is simple, and to me valuable; it was constructed by Dr. Locke, of Cincinnati, to whom I am greatly indebted, not only for the instrument, but for the advice on various subjects, and the interest he has taken in my welfare. I now marked on a number of the way-bills (which Dr. Barnes had politely prepared for me) the height of the thermometer and barometer, the course and rate I was travelling, and threw these and also a number which were not marked, overboard. Thermometer 50 deg., barometer 24 1-10 inches; course east by south; rate 14 miles per hour. At the time I took my departure the thermometer was 54 deg., barometer 29 3-10 inches. At quarter after seven, passed a little to the left of a town, which if I mistake not was Batavia, the town bell was ringing, music playing, and people shouting. The inhabitants noticed my passing over, I waved my flag and threw out several way-bills to them: I was at an altitude of nearly a mile. I continued to pass over a fine open country. At half past seven o'clock I lost sight of the Ohio river. At eight o'clock I took my second observation. Thermometer 30 deg., barometer 31 inches; course east by south, rate 1 mile and a half in nine minutes; saw Williamsburg to the south of me.

Several clouds were now floating above and below me, and as they had lost their pure white appearance, cast a dullness over all beneath, and robbed me of a scene of grandeur—the setting of the sun. Moisture from the clouds began to accumulate on the surface of my vessel, and to run down my neck, so as to completely soak my pantaloons and feet with water. At 9 o'clock took 3d observation; thermometer 33 degrees, barometer 24 1-10 inches, course east by south, rate 1 mile in 8 minutes. The moon now shone, but it was not clear, and I had but a very imperfect view of the earth. A little before 10 o'clock, water poured down upon me; the blankets and sheets, the ballast bags, mail bag, and every thing on board were wet. I threw out a great weight of ballast to gain a more elevated and drier region in the atmosphere, and in a short time I found myself in a situation, though drier, much more unpleasant. The silk had become as hard as wood, icicles hung from the valve rope; I stood in wet clothes upon blankets and sheets that were stiff with ice, and if ever I felt cold in my life, it was at this time. I felt desirous to know the height of the thermometer and barometer, but it was with great difficulty that I

could hold my phosphorus bottle to see their height, the thermometer 10 degrees, the barometer down to 15 inches.

I felt badly and sick at the stomach, and was stiff with cold and wet, and it was with the greatest difficulty, and only by beating my arms and body, and stamping with my feet, that I was enabled to keep awake; for I caught myself, even when in the act of striking my body, a nodding, and falling insensibly asleep. The cause of this drowsiness was the coldness and rarification of the atmosphere.—Being desirous of preserving my gas, I would not open the valve to descend to a milder atmosphere; I soon found myself descending, and found that I had to discharge a quantity of ballast, more than double the quantity I discharged on my former voyage, to keep me at a safe distance from the earth. At first I thought the loss of the levity of my vessel was owing to the accumulation of water and ice on its surface; but I have since found it was owing principally to two holes which I discovered and temporarily mended before I left Cincinnati, but which had broken again and formed large apertures. At 10 o'clock, I felt too cold to pay any attention to my rate of travel. Shortly after, passed a little to the left of Florence. At 11 o'clock, took an observation; thermometer 35 degrees, barometer 24.1-10 inches, course about east by north, rate 1 mile in 6 minutes. At 12 o'clock thermometer 40 degrees, barometer 26 inches, course east by north, rate 10 miles an hour.

After dark, the objects I took for measuring the angle, for ascertaining the rates of travel, were lights that appeared every now and then to pass beneath me. Before one o'clock, the moon was down, and I was left with no better lights to cheer me over the wilderness than a few stars that appeared to struggle through the vapor or mist through which I was floating. I thought before the moon went down, I should have sufficient ballast to keep me afloat till sunrise, but at half after one o'clock my last bag of sand went overboard, next in turn went my six bottles and their contents and provisions, then my cable and anchor, and after a while I found myself again descending; then went my blankets and sheets, and soon after my great coat, and at last some of my instruments, and after all I could not keep afloat till sunrise. My vessel had sprung a leak, and altho' all her valuable burthen, except myself, had gone overboard, yet she was compelled to sink to the bottom of her element.

I at last found myself gently touching the tops of the trees in a dense wood. I stopped myself with one hand without any difficulty, for I was not moving, nor had been for the last half hour, at a rate exceeding two or three miles per hour. I could perceive that there was no space between the trees to bring my vessel to the ground. I therefore secured her by means of a rope to a branch, and then laid myself down in my cold and disagreeable berth, without any great coat, or blanket, or drink to warm me, and with nothing to gaze upon but darkness, or to listen to but frightful noises in the woods. As soon as the sun arose in the morning, I began to exercise my lungs for the purpose of attracting some one to my assistance, but could not succeed in making any one hear.

At seven o'clock in the morning I unlashd my vessel from the tree and drew her to within twenty feet of the ground, and descended by the means of a rope. I struck off in a due West direction, marking the trees so as to be enabled to find my way back. I soon found a path which led me to Mr. Bryan's house, about a mile from where I descended. The news of the man having arrived who had travelled through the air from Cincinnati to the Alleghany Mountains, spread in quick time for miles around, and a great number of ladies and gentlemen came to see me and my aerial ship. I allowed the "Star of the West" to remain inflated and to ornament the woods until Sunday evening. I was then kindly assisted by Mr. Bryan, Mr. Beanning, (Justice of the Peace,) Mr. Pennelton, and two or three others. We cut down several trees, and were enabled to secure her without any injury.

The spot on which I landed is in Pebble township, Pike county, nine miles from Picketon, 18 miles from Chillicothe, and 100 miles from Cincinnati. The letters entrusted to my care were safely deposited in the Post Office at Waverly, a few miles from where I landed.

I take this opportunity of expressing my grateful feelings to the ladies and gentlemen of Cincinnati and its vicinity, for their liberal patronage on the day of my ascension, and to assure the public that

had it not been for the unforeseen escape of gas through the apertures before alluded to, I would have remained in the atmosphere at least 30 hours, and have accomplished my proposed voyage to the Seaboard.

R. CLAYTON.

Cincinnati, July 9, 1835.

**NEW YORK STATE TEMPERANCE SOCIETY.**—The New York State Temperance Society commenced its annual meeting at Buffalo on the 9th inst. A great number of members and delegates were in attendance. The meeting, after a call to order by Mr. Dwight of Geneva, was opened with prayer by Rev. Dr. Edwards, Corresp. Secretary of the Society. Mr. Hartly of New York, and Mr. Willmore of Buffalo, were appointed Secretaries of the meeting. The report of the Executive Committee was read by the former, after which, the Rev. Mr. Kirk, of Albany, moved that it be accepted and printed. Judge Hopkins, of Geneva, objected. It advanced sentiments, and laid down principles, that he could not agree with—and he did not expect the discussion of them would come up at this early hour. He did not wish the report to go forth as the expression of the Society's views. After some remarks, in which Messrs. Kirk, Potter, Leavitt and others took part, it was resolved to lay the report on the table, to be called up at a future time. "From unequivocal indications," says the Buffalo Commercial Advertiser, "there will be great interest excited, much feeling exhibited, and talent displayed during the session of this Convention, in discussing the great question of abstaining from all drinks that can intoxicate."

In the same paper of the next day, we find the second day's proceedings, which consisted principally in the reading and discussion of the following resolution:

Resolved, That this meeting cordially approve the resolution and preamble adopted by the American Temperance Society at their Eighth Anniversary, to wit:

As it has been proved by the experience of thousands in the United States, of all classes of persons, and in all kinds of lawful business, that abstinence from the use of all kinds of intoxicating liquor as a drink, is not only safe but salutary, (and as this is the only course in which it can be rationally expected that intemperate persons will ever be permanently reformed) and as the example and kind moral influence of the temperate is the only means of leading the intemperate to adopt and continue a course so essential to their present and future weal: therefore,

Resolved, That the more extensively this course is adopted by all classes in this community, and especially by all members of temperance societies, the more rapid will be the progress of the Temperance Reformation, and the more certain the prospect that drunkenness and its evils will cease.

The resolution was opposed by Judge Hopkins, of Geneva, and advocated by several gentlemen, among them Mr. Bidwell of Canada. When the vote was finally taken, it was unanimous with one single exception, and the gentleman who made this exception, afterwards withdrew his opposition.

Mr. Kirk, from the committee appointed to prepare an address to the people of this State, reported for that purpose, which he then read, accompanied by a few prefatory remarks.

The address recommends the general adoption of the pledge of total abstinence from all intoxicating drinks, as the only method of advancing the Temperance cause, of effecting any extensive and permanent reform, or in fact retaining the ground it has already won. After briefly alluding to the falsity of the statement that the ulterior measures of the advocates of Temperance contemplated the proscription of Tea and Coffee as beverages, the question as to the use of Wine, on scriptural authority, is treated at much length.

**NIGHT FERRY TO HOBOKEN AND NARROW ESCAPE.**—A man fell overboard from the steamboat Constellation, about 2 o'clock this morning, and was picked up by the Hoboken ferry boat *Fairy Queen*, near the middle of the river. It was not known that the man was overboard until his cries were heard by those on board the F. Q. This fortunate rescue is the more remarkable, from the fact that last night for the first time, the night boat ran—and will henceforth continue to run all night between this city and Hoboken.

**FINE STEAMBOAT.**—The New York Gazette gives the following description of a very fine boat now building here, to be run on the Sound:

We were particularly struck with the appearance of a new steamboat now on the stocks in Messrs. Brown and Bell's yard. On inquiry, we learned that she was intended to ply between this city and Providence, in connection with the Boston and Providence Railroad Company. She is 200 feet long, 30 feet beam and 12 feet hold, with copper boilers; two engines of 110 horse power each, and 9 feet stroke. She will be built entirely of live oak, white oak, locust and cedar, and, when completed, will, in our opinion, surpass in strength and durability any steamboat in the country. The superintendence of her construction is entrusted to Capt. William Comstock, who has been long and favorably known as commander of one of the New York and Providence steamboats, and who is, in every respect, competent to the duties assigned him. We advise all those who are desirous of viewing a beautiful specimen of naval architecture, to make an early visit to the above yard. Now they can have a good opportunity of examining her, but in a few days it will be too late, as they will commence planking her. This boat will be launched early in October, and be ready to take her place on the river at the opening of the season in March next.—The enterprising owners, who have spared no expense in her construction, have our best wishes for their success.

[From the Jersey City Gazette.]

**LAUNCH.**—A steamboat of about one hundred and fifty tons burthen, will be launched at noon, this day, from the foot of Essex street. A boat of the same size was launched from the same place on the morning of the 4th inst. We understand they are destined for Havana, and are intended to ply as ferry boats between that place and the Rigoleta. These boats were built by Mr. Wm. H. Brown, of New York.

Next week the keel of a new boat will be laid at the same place, to be placed on our ferry. By the time she is ready, we have no doubt that the increased travelling will require the constant use of three day boats.

**NAVY DEPARTMENT.**—Copy of a letter received from the Commandant United States Navy Yard, Pensacola, dated 2d July, 1835.

Sir—I have the honor to report that the sloop Vandalia sailed from this port on the 1st inst., and the sloop St. Louis sailed this day.

I also report the arrival, this day, of the schooner Grampus, Lieutenant Commandant White, from a cruise.

I have the honor to be, very respectfully, sir, your obedient servant, WOLCOTT CHAUNCEY.

To John Boyle, Esq.,

Acting Secretary of the Navy.

**NAVAL.**—The Boston Commercial Gazette says the Independence 74, which has been lying in ordinary at the Navy Yard in Charlestown, if we remember right, about fourteen years, was hauled along side the wharf a few days since, preparatory to a thorough overhauling and repair. She is now discharging her kentledge, and will probably be taken into dock about the middle of August, previous to which the Navy Commissioners are expected to arrive, on their annual tour of examination. The outer and inner plank are already, in many places, stripped off, being found very defective, and this will probably be the case to the water line; but what is of far more consequence, the timber composing the frame of the vessel, although it will undoubtedly require being renewed in some few places, is, generally speaking, sound, and in excellent order.

The Independence was launched in Charlestown from the same ship house under which the Vermont is now upon the stocks, about twenty or twenty one years ago, and was the first 74 about belonging to our Navy. She is lighter, we believe, than either of the others, and is considerably smaller than any that are now upon the stocks, and shows a battery of only 54 guns, having none in her waist. She is to be repaired forthwith, but will probably be not ready for service much short of a year.

The sloop of War Boston, built at this yard about ten years ago, has just been refitted, having undergone a thorough overhauling and repair in the Dry Dock, whence she has recently been taken.

The Boston is of the largest size, mounting 24 24-pounder medium guns, and is now to all out-

ward appearance, with the exception that her sails are not bent, ready for sea, and is only waiting for orders. She is one of the most beautiful vessels we ever set our eyes on, and will be a credit to our Navy wherever she goes.

The Convention of N. C. for amending the Constitution, after sitting five weeks, adjourned on the 11th inst. The following are the chief alterations proposed in the Constitution:—

1. Equalizing Representation in both Houses.
2. Changing the Sessions of the Legislature from annual to biennial.
3. Taking the election of Governor from the Legislature and giving it to the People, and making it biennial instead of annual.
4. Altering the term of Office of the Attorney General from continuance during good behavior, to four years.
5. Excluding Borough Members in future.
6. Abolishing the right of free persons of color to vote.
7. Requiring the General Assembly, in the election of all Officers, to vote *vis voce*.
8. Amending the 32d Article of the old Constitution so as to admit Roman Catholics to a participation in the Offices of the State Government.
9. Providing for future amendments of the Constitution.
10. Providing a mode for the Impeachment of Judges and other Officers.
11. Providing for the Removal of Judges for mental or physical disability.
12. Providing against unnecessary private legislation.

These amendments are to be submitted to the People for their ratification or rejection, on the 2d Monday in November next.

**VALUE OF LOTS IN DETROIT.**—By the annexed paragraph of the Detroit Journal of 10th inst., it will be seen that, elsewhere than in this city and its vicinity, real estate has enormously increased in value:

**LAND SALES.**—The auction sale in this city on Tuesday last, of the valuable lots brought into the market by Gov. Cass, was crowdedly attended. The amount of sales was far beyond all expectation. The lots sold, averaged from 15 to \$1400, and yet it is verily believed that these same lots, in two years from this, will readily command double the money. The total amount of sales on the Cass farm was \$69,000. Other sales were made during the day amounting to \$11,000. It was most fortunate for our modest, though enterprising citizens, that none of the capitalists of New York were here, and it is to be hoped that they will stay at home for the present, or at all events not cross Lake Erie until we ourselves shall be plentifully supplied from the rich resources of Michigan, our Railroad and Manufacturing stock distributed, and our senses fully restored.

But a small portion of the Cass farm is yet sold, yet it has yielded its owner \$169,000. It will be remembered by many of our citizens that Gov. Cass would have readily taken \$69,000 for the whole farm four years ago. It was offered for that sum, but no buyers were to be found.

The Apalachicola (Florida) paper of the 15th June, informs us that the citizens of that place have all, without a single exception, resolved to abandon it *en masse*, and remove to St. Joseph's, which, as respects its harbor, local situation, and salubrity, is regarded as a much more eligible site. They have been induced to take this decisive step by what the editor calls the child's play and quibbling course of the proprietors, who appear to be non-residents. The harbor of St. Joseph's is described as being excellent, and it is announced that Apalachicola will have to bow to it in silent submission.

**RUMORED INSURRECTION OF THE FREE COLORED APPRENTICES OF JAMAICA.**—Hudson has at his News Room, a letter, via Philadelphia, from his Jamaica correspondent, without a date, saying that the whole island was in a state of alarm, by reason of the riotous and insubordinate conduct of the apprentices. The Governor, too, is said to be unpopular for his efforts in behalf of the blacks. The whole story is very vague.

The corner stone of a new Episcopal Church (St. John's) was laid at Mount Morris, Livingston, co., on the 3d inst. by the Rev. Dr. Whitehouse of Rochester, assisted by the Rev. Thomas Meacham, rector of the parish, with appropriate religious ceremonies. Address and sermon by the

Rev. Dr. Whitehouse; morning service by the Rev. R. Kearney of Avon, and the Rev. Wm. P. Page of Genesee.

**NEWS FROM CAPT. BACK.**—We learn from the Montreal Gazette, that GEORGE SIMPSON, Esq., the Governor of the Hudson's Bay Company, arrived on the 14th instant at Lachine from the interior, accompanied by J. D. Cameron, Esq. one of the wintering partners of the concern. These gentlemen bring favorable reports of the state of the country—it is remarkably healthy, and the Indians are peaceable and well disposed. When in the interior, Mr. Simpson received a letter from Captain BACK, dated at Fort Reliance, near Great Slave Lake, 7th December, 1834. The gallant officer and his whole party were at the time of writing, in the enjoyment of good health and spirits.

**SINGULAR DEVELOPMENT.**—By an article in the last number of the Boston Medical and Surgical Journal, it appears that since the death of Sir Everard Home, whose reputation for medical and surgical knowledge has become almost unbounded, in consequence of his essays, strange disclosure has been made, to the effect that the writings in question were stolen, bodily, from the manuscripts of the late eminent John Hunter, preserved as the property of the nation in the Hunterian museum, of which Sir Everard was one of the curators, and thus had free access to the manuscripts therein contained. After making such use of Hunter's papers as he thought proper—that is, copying from them *verbatim*—he destroyed them to conceal his theft to the amount, it is said of ten large folio volumes. These circumstances are represented to have become known in the course of an examination of Mr. Edward Clift, formerly a pupil of Mr. Hunter, before a committee on medical education in the House of Commons.

[From the Norfolk Herald, of Friday.]

On Tuesday the President visited Fort Monroe, and reviewed the troops. The steamboat Old Dominion carried down nearly a hundred persons from this place to see the review, and also the target firing with 33 pound shot, which had been announced to take place during the day; but they were cruelly disappointed: the review was over two hours before they arrived, and the target could not be adjusted in its desired position (mid-way the channel between Fort Monroe and the Rip-Raps) in consequence of a strong breeze and a high swell. But they saw the President and a crowd of strangers, and partook of the good cheer at the Hygeia, and came home tolerably well reconciled.

[From the North River Times.]

**EXTRAORDINARY CIRCUMSTANCE, and Providential escape from Death.**—On Monday of last week, the hands employed in the quarry of Mr. Harman Lydacker, situated under the high range of mountains, below Slaughter's Landing, in this county, were alarmed by the cry of murder! proceeding from a female voice, but were totally unable to discover the source from whence it came. At the same moment the crew of the sloop Henry Edward, which was passing down the river, saw something suspended at the side of the mountain resembling a female form. With commendable promptitude they immediately put about, dropt anchor, and jumping into the small boat, rowed to the shore. On arriving at the foot of the mountain, they found it to be a young girl, (aged about 16,) hanging by one foot in a cedar bush, about 100 feet from the base, and 80 feet from the top of the perpendicular rock. To reach her from the bottom was impossible, and providing themselves with a rope, they hastened around to the top from which they lowered it. The unfortunate girl was yet able to fix it around her waist, and by this means, was drawn from her perilous situation, and rescued from impending and almost certain death. She proved to be Miss Phebe Wells, a niece of Mr. Benedict Wells, who had left his residence without the knowledge of his family, with a view of going to New York to see her friends. Unacquainted with the passage of the mountains, it is supposed she was unaware of the danger until she found herself descending the precipice, and the rock being nearly perpendicular, her fall could only have been broken by the slight shrubbery which projects from the side of the cliff, until, luckily for her, she struck the cedar bush, in which her foot fortunately caught.

Her situation here may be imagined, it cannot be described; hanging by one foot to a slender bush, and a yawning gulf of rocks and stones 100 feet below—unable to extricate herself, and for aught she knew, far beyond the reach of human call. It is not at all probable that in five hundred thousand cases, one could have passed the cliff she did, and not have been dashed to pieces long before reaching the bottom. She was not materially injured, and was conveyed to her friends in New York by the sloop Henry Edward, the captain and crew of which are entitled to the highest commendations for their promptitude and humanity.

**Yankee Peddlers** are fruitful in expedients to attract customers. One of the craft passed through our village last week, with a wagon load of wooden ware drawn by a nice looking steer, harnessed in horse fashion. This rather novel mode of travelling attracts as many gazers around the wagon, as if a dancing bear was attached to it, and it is a great chance if some of them are not metamorphosed into purchasers. A year or two since, this same character passed through here with a cow attached to his wagon. When hungry, he was in the habit of milking *mully* and regaling himself with a bowl of bread and milk. At that time we could not but be struck with the manifold advantages of a travelling concern of this description. We can't conceive why the fellow has substituted a steer for his cow, unless he has got married, and is thus enabled to keep his provision chest well stocked.—[Greenfield Gaz.]

#### EUROPEAN INTELLIGENCE.

The accounts from Europe, by the *Caledonia*, as to the partial intervention by France and England in the affairs of Spain, indicate a new line of policy in such matters.

Instead of marching armies, or sending fleets of the nation, to the people whose form of government the intervention is to settle, the matter is now left to private enterprise, by the simple repeal of the general prohibition against enlistments or the sending of supplies, to countries distracted by civil war.

These prohibitions are now in force, both in France and England, only against Don Carlos and his partisans; but the Queen may derive men and arms, provisions and money, if she has credit enough, from either nation.

This strikes us as quite an improvement in politics. It is intervention upon the true principle of free trade, leaving the supply to be regulated by the demand, and especially leaving it to the party benefitted, or supposed to be so—to pay the cost—instead, as heretofore, of that being paid by the nations intervening.

The correspondent of the London Times describes *Zumalacarraguy*, it will be seen, as possessing in an eminent degree, the qualities of an insurgent commander. The most daring personal valor, the greatest simplicity of manners and attire—and the power of combining movements on a large scale.

COL. EVANS, member of Parliament from Westminster, is announced in the London papers, as designed to command the British legion about being recruited for the young Queen. He is spoken of as a soldier, tried in the Peninsula and in this country.

The change of Ministry in Portugal is looked upon disagreeably, it is said, in England, chiefly on the ground that it implies a disposition on the part of the Queen to connect herself with the French reigning family, by marrying the Duke of Nemours.

Count Pahlen has been appointed Russian Ambassador at Paris, in the place of *Pozzo di Borgo*, who had so long occupied that station.

The most interesting intelligence is that which relates to the indemnity due by France to this country. The London Morning Herald of the 15th says:—"The domestic news given by the Paris papers is highly interesting. The Chamber of Peers passed the American Indemnity Treaty Bill on Friday last by a large majority (125 against 23), in the shape in which it had been brought up from the Chamber of Deputies; thus defeating all the speculations that the clause introduced into it in the latter mentioned Chamber, on motion of Gen. Vissot, and which it was thought would give offence to America, would be omitted.

**Limer on the Death of Mrs. Hemans.**  
 "Bring flowers, fresh flowers, o'er the bier to shed,  
 A crown for the brow of the early dead."—*F. Hemans.*

Gather flowers, and bring the fairest,  
 Let them early, drooping, wave;  
 Hither group the sweetest, rarest,  
 To wither round the poet's grave!  
 Let their dying perfume faintly  
 Haunt, like dew drops, fall with tears,—  
 Sign, in aspirations faintly,  
 O'er the home of hopes and fears.  
 Mourn the Muse, whose strains once breathing  
 All the soul of woman's love;  
 Joyous chords, with gems unweaving,  
 Garlands her own hand had wove:  
 Songs that waked the chieft to glory,  
 Ere the battle's din was o'er;  
 Songs of sweet, domestic story,  
 Ye, alas! are heard no more.  
 Hearts, in apathetic slumbers,  
 By her gentle, matchless mind  
 She awakened with her numbers,  
 And the soul of sense refined.  
 Fame has spread her wings of gladness,  
 Echoed from the princely dome,  
 While her simple lays of sadness  
 Bless the lowly cottage home.  
 Once her trembling chords revealing  
 Deeper thoughts, in mournful shade,  
 Vain a breaking heart concealing  
 Hopes that promised, here betrayed;  
 Hopes she had in spring time cherished—  
 The bruised reed—the flower crushed—  
 A delusive wreck—had perished,  
 Ere her lyre and voice were hushed.  
 Mourn her loved and honored name,  
 Which Genius to the world hath given;  
 Her soul, beyond the breath of fame,  
 Shall find felicity in heaven.  
 Her song of sorrow now hath ceased,—  
 Mute her lyre, and cold the hand;  
 Her broken spirit God appeased,  
 And called her to the better land.

**CIRCULAR. To ENGINEERS and Superintendents of Railroads and Canals.**—I am preparing to issue a new edition of my **RAILROAD AND CANAL MAP**; and being desirous to correct the errors of the first edition, I make the liberty to request the **ENGINEER, or SUPERINTENDENT, of every Railroad and Canal in the UNITED STATES**, to furnish me at his earliest convenience with a full and precise account of the condition of the railroad under his direction or charge. He is requested to state the length of the road, the number of miles completed, the elevation it surmounts, the radius of its curves, the style of its construction, its average cost per mile, the number, if any, of inclined planes, with stationary engines—in short, every thing which may be of interest to engineers, or others who may be connected with the subject of Railroads and Canals.

To each as comply with the above request, and furnish the desired information previous to the first of August next, a copy of the new edition of the **Railroad and Canal Map**, will be sent, by mail or otherwise, as may be directed, as soon as completed.

D. K. MINOR.

New-York, June 27, 1835.

#### RAILROAD JOURNAL AND ADVOCATE OF INTERNAL IMPROVEMENT.

This work is published once a week, in quarto form of EIGHT pages, devoted mainly to the subject of internal improvements, in all its various modes and forms.

Three volumes were completed in December, 1834, and the 4th volume is now in progress.

Terms, \$3 a year, IN ADVANCE. Previous volumes same price; full set of four volumes, \$12.

#### RAILROAD AND CANAL MAP.

Or a Map of the United States, 24 by 40 inches, on which is delineated all the Railroads and Canals in use, or in course of construction, and most of those in contemplation; together with a concise description of, or reference to, each, and containing over 70 pages of letter press. The map is on bank note paper, and put up in pocket form, with morocco cover, or in paper cover, and may be sent by mail to any part of the country Price \$3

#### THE APPRENTICE'S COMPANION—

A monthly publication, in large octavo form, of sixteen pages each number—designed to persuade APPRENTICES, and others, to habits of INDUSTRY, TEMPERANCE, and FRUGALITY—in published at the office of the **MECHANICAL MAGAZINE**, No. 25 Wall street, New-York, for FIFTY CENTS a year—for 18 numbers—by D. K. MINOR.

\* All letters must be postage paid. Eleven numbers sent to one address for \$5,—and TWENTY THREE for \$10. D. K. M.

#### NEW-YORK FARMER AND AMERICAN GARDENER'S MAGAZINE.

This work is devoted mainly to AGRICULTURE and HORTICULTURE; it, however, treats upon various other subjects more or less connected with them. It is now in its 8th volume, or 3d volume, new series, and is designed to be made equal to any work of the kind in this or any other country. No reasonable expense will be spared, either to secure the best writers the country affords, or to furnish engravings and illustrations. It is published monthly in large octavo, 32 pages per month, at \$3 per annum, and when paid in advance eight additional pages per month are given—Vols. 6 and 7, or 1 and 2, new series, \$3 per volume.

These works may all, or either of them, be had of S. Blydenburgh, 95 North Pearl street, Albany; D. Hale, 124 Washington street, Boston; Fowenden, Philadelphia; or of the Proprietor and Publisher,

D. K. MINOR,

35 Wall street, New-York.

#### PARTNER WANTED.

Wanted, a partner in an extensive Printing Establishment. No one need apply who is not a thoroughbred printer, competent to superintend and direct an office in which upwards of 30 persons are employed, and able to furnish \$3000 cash capital. The best of references will be given and required. Letters, with real names, may be addressed to F. P. P., Post Office, New-York, postage paid, and they will be promptly attended to. May-4

#### TO TUNNEL MINERS, DRILLERS, &c.

Wanted, immediately, 40 Tunnel Miners, (Carroll Miners will be preferred), 50 Drillers, 30 Laborers, and two experienced Mine Blacksmiths, on the New York and Harlem Railroad, about five miles from the City. Liberal wages will be given, and cash payments made every fortnight. Apply at Mr. FOWLER'S, St. John's Hall, Frankfort street, New-York.

JOHN BUTTER, Contractor

At the Albany Argus, Philadelphia U. S. Gazette and Freeman's press, will please copy this, and send their bills to the Railroad Company, 14 Wall street, New-York. 23-4

#### RAILROAD IRON.

300 Tons Railroad Iron, 2 inch by 4, with Spikes and Splicing Plates to match, for sale by

WM. G. BULL & CO.  
 74 Wall-st.

#### RAILROAD CASTINGS.

MANT & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order cast wheels, chairs and knees, and every other description of castings required for railroads R-1y Table

#### PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

At the Albany Spikes Factory, every description requested, made at the Albany Spikes Factory.

Spikes made at the above Factory are recommended to be put to use superior to any thing of the kind now in use. Ship and Boat Spikes made fell size under the head, so as not to sink water.

Orders may be addressed to Messrs. CRATUS CORNING & CO., Albany, or to THOMAS TURNER, at the Factory, Troy, N. Y. sep.18-17

#### PATENT RAILROAD, SHIP AND BOAT SPIKES.

The Troy Iron and Nail Factory keeps constantly for sale every extensive assortment of Wrought Spikes and Nails, from 2 to 10 inches, manufactured by the subscriber's Patent Machinery, which after five years successful operation and now almost universal use in the United States (as well as England, where the subscriber obtained a Patent,) are found superior to any ever offered in market.

Railroad Companies may be supplied with Spikes having counter-sunk heads suitable to the bolts in iron rails, to any amount and on short notice. Almost all the Railroads now in progress in the United States are furnished with Spikes made at the above named factory—for which purpose they are found invaluable, as their adhesion is more than double any common spikes made by the hammer.

All orders directed to the Agent, Troy, N. Y., will be practically attended to.

HENRY BURDEN, Agent.

Troy, N. Y. July, 1835.

Spikes are kept for sale, at factory price, by J. & J. Townsend, Albany, and the principal Iron Merchants in Albany and Troy; J. I. Brower, 235 Water street, New-York; A. M. Jones, Philadelphia; T. Janviers, Baltimore; DeGrand & Smith, Boston.

P. S.—Railroad Companies would do well to forward their orders as early as practicable, as the subscriber is desirous of extending the manufacturing as early as possible with the daily increasing demand for his Spikes.

1835

H. BURDEN.

#### STEPHENSON.

Builder of a superior style of Passenger Cars for Railroads.

No. 364 Elizabeth street, near Blocker street, New-York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. J M d

#### RAILROAD CAR WHEELS AND BOXES, AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscriber at Paterson, or 80 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS

Also, Flange Tires turned complete.

JO ROGERS, KETCHUM & GROSVENOR

#### RAILWAY IRON.

24 tons of 1 inch by 1 inch, Flat Bars in lengths of 200 do. 14 do. 14 to 16 feet, counter sunk holes, round cut at an angle of 25 degrees, with splicing plates and nails to suit soon expected.

250 do. of Edge Rails of 36 lbs. per yard, with the requisite chairs, keys and pins Wrought Iron Rails of 30, 32, and 36 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels

Also of 24, 26, 28, 30, 32, 34, 36, and 38 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment.

A. & G. BALSTON

3 South Front street, Philadelphia. Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them. J M d

#### SURVEYOR'S INSTRUMENTS.

Compases of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with scales made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by

E. & G. W. BLUNT, 144 Water street, corner of Maiden lane.

J M d

#### SURVEYING AND ENGINEERING INSTRUMENTS.

The subscriber manufactures all kinds of Instruments in his profession, warranted equal, if not superior, to principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Goniometer, with two Telescopes—and a Leveling Instrument, with a Goniometer attached, particularly adapted in Railroad purposes.

W. J. YOUNG,

Mathematical Instrument Maker, No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested. Baltimore, 1835.

In reply to thy inquiries respecting the instruments manufactured by thee, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish thee the following information. The whole number of Levels now in possession of the department of construction of thy make is seven. The whole number of the "Improved Compass" is eight. There are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accidents to which all instruments of the kind are liable.

I have found that thy patterns for the Levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a reversing telescope, in place of the vane sight, leaves the engineer scarcely any thing to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,  
 JAMES F. STABLER, Sup't of Construction of Baltimore and Ohio Railroad.

Philadelphia, February, 1835.

Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Germanstown, February, 1835.

For a year past I have used Instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these Instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

KENNY B. CAMPBELL, Eng. Philad. Germantown, and Norrist. Railroad

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, AUGUST 1, 1835.

### HARTFORD AND NEW-HAVEN RAILROAD.—

We give to-day a long extract from the Report made by ALEX. C. TWINING, Esq., of his survey of the route for a Railroad between these two cities. This road by itself would undoubtedly be a profitable work; but, taken in connection with others, which will beyond all question be constructed between Hartford and Worcester, and up the valley of the Connecticut river to Windsor, Vt., and eventually to Canada line, it will become one of the thoroughfares of the country.

We should have given this Report in our last, if it had been received in time—and have called attention to the opening of the books yesterday at the Union Bank in this city, for subscription to the stock.

The Winchester Republican of 23d ult., says that "William H. Morell, Esq., has been appointed Engineer in Chief of the Winchester and Potomac Railroad Company, to fill the vacancy occasioned by the resignation of Monsieur Robinson, Esq. This is a most excellent appointment. Mr. Morell comes from a race distinguished, in their native north, for talent and worth; and he adds to these qualities, energy and experience in his profession."

The Alton Spectator says that "the survey of the Railroad route between Springfield and Alton progresses, according

to our last accounts, with rapidity and success, under the auspices of General Mitchell."

**ANOTHER LINK.**—The great Atlantic Railroad progressing.—The Portsmouth Journal says: "We are happy to announce to our readers the gratifying intelligence, that the stock in the Railroad from this town to Massachusetts line in the direction of Newburyport and Boston is taken up."

"On Thursday, the Committee appointed at the meeting of Tuesday evening, made preparations to open a Subscription for the Railroad Stock, and in the evening a few individuals subscribed. Yesterday morning the books were opened at several places of resort, and before noon the entire capital Stock, amounting to *Two Hundred Thousand Dollars* had been taken,—the anxiety to obtain Stock being so great, that the Committee were induced to increase the capital stock *fifty thousand dollars* beyond what was contemplated by the meeting of Tuesday evening."

**AND YET ANOTHER.**—The Philadelphia Commercial Herald says: We learn that a general meeting of the Stockholders of this Company was held yesterday, at which it was unanimously resolved to increase the Capital Stock of the Company, from six hundred thousand to one million of dollars. This amount will enable the Directors to complete without delay, the entire route between Trenton and New-Brunswick, by means of a Railroad, on the route of the present Straight Turnpike, to build a Bridge over the River Delaware, at Trenton, and to complete a second track between this City and Morrisville. A resolution was also unanimously passed, approving of the purchase by the Directors of the Philadelphia and Trenton Railroad Company, of the majority of the stock of the Straight Turnpike."

**COLUMBIA RAILROAD—INCLINED PLANE.**—The Philadelphia Herald says, "We learn that there is strong probability of a route being obtained by which the inclined plane on the west side, and near the Schuylkill river, may be avoided and the rise overcome by a grade of not more than 25 feet to the mile. The route leaves the present road at the foot of the plane, and leans to the right

for about fifteen miles, when it again unites with the road. By this route the distance is increased only about a mile and a half. A reconnoissance was made of this route at the request of the Canal Commissioners, by Mr. Gill, who deemed it practicable. Mr. Gay, we understand, is now engaged in making a minute survey of the route. If the plane can be dispensed with, the public will undoubtedly demand that it shall be done."

Is it not singular that a discovery so important should have been made at *this late period*? If so, it would appear that a desire to complete, had entirely cast into the shade the importance of selecting the best route for, this *great work*. It is however better, even late than never, to discover and acknowledge our errors.

[From the Pitsburg Advocate.]

**EXTENSION OF THE BALTIMORE AND OHIO RAILROAD.**—The visit of Jonathan Knight, Esq. to our city having attracted attention to this important subject, a meeting of the citizens of Pittsburgh and its vicinity took place at the Exchange, on Friday, the 24th inst. A full and frank conference was held with that gentleman, in which he expressed the belief that a liberal subscription at this place would lead to the immediate undertaking of the western section of the road, and insure its termination at Pittsburgh. It being now certain, through the liberality of the Legislature of Maryland, that an artificial communication will be completed from Baltimore and Washington to Cumberland, the question is one of vital importance to Pittsburgh—what course the trade shall take from that point? The meeting having fully come to order, by appointing Isaac Lightner Chairman, and Geo. Cochran Secretary, the following resolution was unanimously adopted:

Resolved, That a committee of seven be appointed to correspond with the officers of the Baltimore and Ohio Railroad, on the subject of the contemplated extension; to ascertain the condition and stipulations which may accompany any subscription made at this place, and to take such measures generally as shall seem best calculated to place the subject in all its bearings before our citizens, in a distinct and authentic form.

The chairman appointed the following committee: Richard Biddle, W. Robinson,

Jr., Wm. Hays, James Brown, Wm. Wade, Thomas S. Clark, and Charles Shaler.

On motion, the chairman was added to the committee.

On motion, Resolved, That the proceedings of the meeting be published.

ISAAC LIGHTNER, Chairman.

GEO. COCHRAN, Secretary.

[From the Baltimore American.]

We made a day or two since a trip on the Washington railroad, starting with a train of three commodious and very large cars, each capable of holding sixty passengers, and all drawn by one steam engine. The average speed of the train was about eighteen miles per hour, and it frequently exceeded twenty five, the engine being under perfect command, suddenly moderating its gait at the curvatures, or in passing the highest embankments, and stopping at a short notice. We had the pleasure of witnessing a new application, not exactly of steam power, but of its generator the boiling water, by the ejecting of which the engineer quickly cleared the road of some obstructing cows.

We take the opportunity of calling the attention of the company to the policy and propriety of accommodating way-passengers. People residing on the line of the road have reason to complain if they cannot have the benefit of its construction, without the inconvenience of going several miles to one of the few regular stopping places. Such too is the facility of arresting the engine that the delay occasioned by taking in or letting out a passenger is but momentary.

The passage of the cars is a novel sight which attracts the inhabitants of the country long distances to witness; and well it may, for it is enough to excite a special wonder to behold a row of long houses roaring along the road, borne at the rate of thirty miles an hour by the snorting engine.

The train came yesterday morning from the depot beyond Bladensburg to that on the outskirts of Baltimore, in one hour and fifty minutes, the distance being about thirty three miles. This is the average time taken to make the trip, and proves that when the whole route shall be completed the passage between Baltimore and Washington will be made with ease in two hours, stoppages included.

**ITHACA AND OWEGO RAILROAD.**—At a meeting of Citizens of Tompkins County held in Ithaca on the 19th instant resolutions were passed in favor of the New York and Erie Railroad. It was also

Resolved, That a cheap and rapid communication from the heart of Tompkins county to our great commercial mart, through the Ithaca and Owego and New York and Erie Railroads, at a much less distance than a circuitous route by water communication, which can be travelled in much less time, and at seasons when the latter cannot be used at all, is a matter of great importance, of which our citizens should not lose sight.

**UNION CANAL.**—During the week ending the 17th inst., the amount of tolls received was \$2,309 11. Former report \$86,417 44. Whole amount of receipts this season, \$88,729 52.

We learn that no boats have passed through this canal from the west, since the breach which occurred, on the 12th inst., in the Pennsylvania canal at Highgate.—[Phil. Com. List.]

**SCHUYLKILL NAVIGATION.**—During the week ending the 17th instant, the receipts for tolls amounted to \$6,792 23. Former report \$180,928 94—making the total receipts this season, \$187,631 22.—[Ib.]

**LEHIGH COAL TRADE.**—Despatched from Mauch Chunk during the week ending the 17th inst., 136 boats, carrying 4458 tons—cwt. Former report, 1381 boats, carrying 48,576 tons—cwt. Total this season 1517 boats, carrying 53,034 tons—cwt. of Coal.—[Ib.]

**RAPID MOVEMENT.**—Passengers who left Norfolk on Monday morning at 6 o'clock in the steamboat Champlain, were in the hotels in Baltimore at half past 7 o'clock the same evening, having made the run in thirteen hours and a half—distance 300 miles.

[From the Worcester Palladium.]

# RAILROAD SURVEY.—ENGINEER'S REPORT.

Boston, July 1, 1835.

To the Chairman and Members of the Executive Committee for the survey of the route of the Western Railroad.

Gentlemen: Agreeably to your request, that I would give some details of the route for the Railroad between Worcester and Springfield, as developed by the surveys and examinations thus far made, I herewith present the following statement, with the remark, that the preliminary surveys are not completed, and further examinations may enable me to improve even upon the favorable route already obtained—I would also add, that I have examined the route from Springfield to Hartford, with a view to the continuation of the road in that direction, and will state the circumstances under which that continuation may be made.

1st. The route to Springfield from the point of junction with the Worcester railroad half a mile east of the Main street in Worcester, by South Leicester, Spencer, Brookfield, Warren, Palmer, Monson and Wilbraham, into the village of Springfield, is 53½ miles in length; the average rise is 9 feet, and the average fall 17 feet per mile going west, and in no place exceeding 34 feet to the mile in either direction; the grading along this route is very generally favorable, and the estimate of cost will be nearly as follows:

For grading, masonry, &c. including engineering and every contingency, \$11,000 per mile, 589,000

The superstructure or Railway including turn outs, \$8000, 428,000  
Land, damages, fencing, engines, cars and depots, 183,000

Total, \$1200,000

2d. The distance to Hartford from this route down the Connecticut river is 23 miles, passing over a remarkably level and favorable country, the fall on which will not exceed 2½ feet per mile—the estimate for cost is for grading, masonry, &c., including a bridge across Connecticut river, Engineering and every contingency, \$6000 per mile, 138,000

For the superstructure or railway, including turn outs, \$8000 per mile, 184,000

Lands, damages and fencing, engines, cars and depots, 78,000

Total, \$400,000

3d. For the whole distance by these routes from Worcester to Hartford, with no radius of less than 1500 feet, we have 76½ miles, and the maximum inclination as stated above, 34 feet to the mile—the average rise to Hartford 6 feet, and the fall 12½ feet to the mile. The estimate is for grading, masonry, &c. including bridge across the Connecticut River, engineering, and every contingency, \$9,500 per mile, 727,000

The superstructure or railway including turn outs, \$8000 per mile, 612,000

Land, damages and fencing, engines, cars and depots, 261,000

Total, \$1,600,000

The foregoing estimates contemplate the use of the heaviest edge rail and the best materials for the superstructure, and all other parts of the work, for engines, cars and depot arrangements, for a much larger amount of the transportation and travel than at present over the route.

The annual expenses on the route from Worcester to Springfield, estimated as I

have before, for a much larger amount of transportation than there is at present between the two places, I think will not vary materially from the following.

For salaries of superintendent and 45 others, to wit:

Assistants, clerks, engine and firemen,	\$21,000
depot and brakemen,	18,000
Fuel for twenty trains per day,	19,000
Repairs and depreciation of engines and cars 18 per ct.	27,000
Repairs of road at 500 dollars per mile,	\$85,000

The annual expenses on the route from Springfield to Hartford would be less in proportion to its length than the above, on account of its directness, and the near approach to a level, and would allow an average rate of travelling 1½ faster than on any equal distance of the route east of Springfield; or the 23 miles between Springfield and Hartford would be run as soon as any twenty miles from Springfield towards Worcester. The preliminary surveys are still progressing, and the approximated location will be made as soon as these are completed. Very respectfully, your obedient servant,

J. M. FRESHWATER, Engineer.

## Extract from the Report of the Engineer, upon the Preliminary Surveys for the Hartford and New-Haven Railroad.

The following table has been arranged with reference to this last mentioned route by Holt's hill, by throwing together all the excavations of a similar depth, and all the embankments of a similar height, in such a way as to give a correct and ready view, both of the extent and depth of cutting and filling, and their relative proportion to each other upon the entire route.

Upon this plan, there will be of excavation and embankment,

Excavation, 2 feet deep, 6.30 miles.	"
do. 6 " " 9.11 "	"
do. 12 " " 2.69 "	"
do. 26 " " .30 "	"
Embankment, 3 feet high, 9.50 miles.	"
do. 6 " " 5.79 "	"
do. 15 " " 2.56 "	"
do. 25 " " .32 "	"
Entire length of excavation, 18.40 miles.	"
do. do. of embankment, 18.16 "	"
do. do. of bridges, .14 "	"

Entire length of route, 36.64 miles.

The excavation will be sand, gravel, and clay, in a nearly equal proportion, with a considerable amount of ditching and wet digging in mud and vegetable matter. The amount of rock is estimated at 88,986 cubic yards,—mostly solid rock, and that chiefly red sand-stone and slate.

The following table is arranged in such a manner as to exhibit the entire extent of the inclinations of the same degree throughout the whole route. It will be noticed, that the steepest inclinations are but thirty feet to the mile.

Ascending to the north.	Inclination to the mile.	Descending to the north.	Extent of similar inclinations.
5.83 miles	Level	13.16 miles	6.57 "
4.18 "	9 feet and under	0.75 "	3.23 "
2.78 "	13½ feet	1.05 "	5.14 "
3.70 "	26½ feet	4.84 "	6.54 "
3.70 "	30 feet		

14.88 miles ascending | descending 9.00 miles | 36.64 miles

About twenty miles of the route is disposed in straight lines. The remaining

sixteen miles and two thirds consists of curves, which may be turned on radii of from five thousand to twenty thousand feet; except at the entrance of the two cities, where curves of about twenty-five hundred feet would probably be expedient.

*Estimate of Grading.*

For the convenience of statement, the line will be disposed into sections, that will be estimated each by itself; and these separate estimates will be brought together, to make the general result. In all the sections, I suppose the road to be thirty feet wide at the level of the grade, (but to provide for contingencies, the calculations are in fact made for a width of thirty-five feet.) A single track only is supposed to be at first employed. The masonry is to be generally dry work, at \$1.50 the perch of twenty-five feet; but at \$3 the perch, when mortared, or dressed with particular care, to joints and beds. The bridges are supposed to be a simple truss-work, or string-pieces, braced from beneath, and sustained by abutments, and sometimes piers of masonry.

**NEW-HAVEN SECTION.**

This commences at the foot of East street, passes the embankment and bridge at Mill river, and the deep cut at the base of East Rock, and ends near the margin of the salt marsh, three miles from New-Haven. Excavation is sand and gravel; the principal body to be transported a half mile by a temporary railway, to form the embankment at the Mill river.

Grading East street, past Barns-	
ville,	\$3,876 50
Embankment at Mill river, and	
excavation opposite East Rock,	18,500 00
Bridge across Mill river, (founda-	
tions to be piled,) 8,174 00	
Road bridge for Middletown	
turnpike,	556 00
One mile light excavation and	
embankment,	2,086 19
Three crossings for farms,	325 00
Grubbing and clearing,	75 00

Cost of New-Haven Section, 3 miles, \$33,592 69

**QUINIPAC SECTION.**

This proceeds with a low grade, along easy ground, to the crossing of the Quinipac, a little south of North-Haven bridge; then upon the sandy plains east of that stream, as far north as to the bend of the river and the foot of the high grounds of Meriden, sixteen miles from New-Haven.

Excavation and embankment,	
thirteen miles,	\$49,595 33
Ditching salt marsh and wet	
ground, 60 chains,	1,200 00
Changing North-Haven road 420	
rods,	1,050 00
Bridge at crossing of Quinipac,	
150 feet long,	2,116 00
Six bridges and two crossings	
for public roads,	3,674 00
Thirteen crossings for farms,	750 00
Culvert, ten feet span, for Hor-	
ton's brook,	1,500 00
Culvert for brook opposite Yales-	
ville,	1,500 00
Ten small culverts,	2,650 00
Grubbing and clearing,	200 00

Cost of Quinipac Section, 13 miles, \$64,235 38

**MERIDEN SECTION.**

This turns from the river into the valley leading to Holt's hill,—cuts through the hill,—passes along much swampy ground to the first dividing summit, and then along the east of the Beaver ponds, ending to the

north of these, nearly opposite the turnpike gate, and twenty-one miles from New-Haven.

Excavation of Holt's hill, 48 chains, viz.:	
Wet earth 33,088 cubic yds.,	
at 20 cts.,	\$6,617 60
Red Rock 32,648 cubic yds.,	
at 60 cts.,	19,588 50

\$26,206 40

Excavation at summit, 36 chains, viz.:	
Earth 10,028 cubic yards, at	
12 cts.,	\$1,203 36
Loose rock 9,000 cubic yards,	
at 25 cts.,	2,250 00
Solid rock 9,000 cubic yards,	
at 60 cts.,	5,400 00

8,853 36

Excavation and embankment, 3	
miles 76 chains,	26,885 40
Harbor brook culvert at Meri-	
den, ten feet,	1,500 00
Culvert for brook from summit,	750 00
Three small culverts,	600 00
Ditching wet ground, 88 chains,	1,584 00
Changing road near Meriden, 50	
rods,	75 00
Two road bridges and one crossing,	1,450 00
Five farm crossings,	500 00
Grubbing and clearing,	350 00

Cost of Meriden Section, 5 miles, \$68,754 16

**BERLIN SECTION.**

This runs along the west margin of the 'Old Fly,' till it cuts through the ridge at its northern outlet; it then passes the defile in the next ridge,—crosses Brandegee's pond on to the Worthington hill, and descends to the Berlin flats, which it passes to their northern border, and terminates at the southern opening of the Green swamp. Length six miles.

Embankment along the 'Old	
Fly,' six feet high for 87	
chains, with ditching and	
clearing,	\$11,564.80
Two culverts for Beaver brook,	1,500.
Excavation through two ridges,	
and embankment across mead-	
ow, &c., to factory pond,	12,541.14
Rock in meadow, 14,600 cubic	
yards,	8,800.
Bridge 200 feet, across factory	
pond,	7,200.
Culvert for Beaver brook,	1,000.
Embankment and excavation on	
Worthington sideslope, one	
mile and a quarter,	8,388.81
Embankment on flat 14 feet high,	
83 chains long,	10,118.88
Excavation and embankment on	
flat, 1 mile 73 chains,	3,850.
A bridge and two culverts for	
streams,	1,850.
Bridge and two crossings,	1,000.
Three farm crossings,	300.
Grubbing and clearing,	125.

Cost of Berlin Section, 6 miles, \$67,736.63

**GREEN SWAMP SECTION**

This extends through the swamp by a low embankment, with wide and deep ditches on each side. It passes on to the table and, cuts through 'Dirty swamp,' and terminates near the brick-yards, on the other side of the gully which is made by a south-western branch of the Hog river. The soil is all clay. Length six miles.

Excavation and embankment in	
swamp, 3 miles 57 chains,	\$10,143.95
Ditches,	3,645.
Culvert, ten feet, for Green	
swamp brook,	1,500.

Bridge for New-Britain road, also	
one crossing,	650.
Two farm crossings,	200.
Excavation and embankment, 1	
mile 76 chains,	14,061.44
Embankment across gully of	
Little river,	7,856.64
Bridge for old road to Farming-	
ton and Hartford,	1,050.
Culvert for branch of Little	
river,	2,500.
Grubbing and clearing,	275.

Cost of Green swamp Section, 6 miles, \$41,872.08

**HARTFORD SECTION.**

This courses along the broken ground west of the Hog river, and enters Hartford from the west, passing between the Asylum and the Hog river, and north of Imley's mills, into Pearl street. Length three miles and fifty-one chains. Soil all clay, and grubbing considerable.

Excavation and embankment to	
doubling of Hog river, 3 1/2	
miles,	\$29,087.77
Rock near Hartford, 18,740 cubic	
yards,	9,870.
Embankment by Imley's mill,	
18 feet high, 30 chains long,	12,276.
One culvert \$1000, and seven	
small do. \$250 each,	2,750.
Four crossings,	408.
Bridge across north-west branch	
of Hog river, 100 feet,	3,592.
Two bridges across doublings of	
Hog river, 75 feet each,	10,068.
Grubbing and clearing,	350.

Cost of Hartford Section, 3 miles 51 chains, \$67,578.77

*Recapitulation.*

New-Haven Section, 3 miles,	\$33,592.69
Quinipac do. 13 "	64,235.38
Meriden do. 5 "	68,754.16
Berlin do. 6 "	67,738.63
Green swamp do. 6 "	41,872.08
Hartford do. 3.64 "	67,573.77

36.64 \$344,066.66

Cost of grading by Holt's hill, 36.64 miles, \$344,066.66, being per mile \$9,390.47.

It may be observed, in passing, that, by the estimates which have been made of the other routes, but which need not be given in detail, the results upon those other routes would vary from the above as follows:

Cost of grading by Sodom brook, 36.95 miles, \$333,998.33; cost of grading by Kensington, say 36.31 miles, \$344,338.84.

*Superstructure.*

Upon the road, when graded, there may be laid, (if in the end such a construction shall be deemed advisable,) a wooden superstructure, with a flat iron rail, at an expense of about \$4000 to the mile. But the policy of adopting such a structure appears to me at present very questionable, both from considerations of economy, arising out of the cost and inconvenience of repairs upon a perishable structure, and from considerations drawn from the relation in which this road will stand to other lines of communication. It can hardly be doubted, that this road, (in addition to its contemplated extension to Springfield,) will, after being made, be speedily extended to Worcester. It will in that case connect with the Boston and Worcester railroad, forming with it one line of communication; and it would seem to be desirable, that the structure of this should not be exceeded in permanent excellence by the structure of that.

Besides, this whole route is to come into competition with other thoroughfares from New-York to Boston,—the most prominent of which will be the Boston and Providence railroad. When we consider the excellent navigation by steamboats, which is open at all seasons from New-York to New-Haven, and the inducements to travellers which are offered by the cities of New-Haven and Hartford, and the town of Worcester, it appears reasonable to expect, that the high advantages of this route will make it, to a greater degree than any other that can be selected, the rival route to the Boston and Providence railroad, (the great amount of whose destined business would soon secure it rivals in any event.) Under an expectation of this sort, it would be shortsighted to calculate for any thing less than a superstructure of a very substantial and excellent kind; and it would be, to say the least, unsafe, in our early operations, to incur the hazard of trammeling the future directors of this work, by estimating now on the idea of a cheap but perishable structure, when there is a prospect that they may wish to adopt a durable but more expensive one. I am decided, therefore, as to the propriety of making an imperishable construction the basis of these present estimates.

Among the superstructures of this character which have been either proposed or adopted, I prefer the one which has been arranged for the Brooklyn and Jamaica railroad by Major D. B. Douglass, the Engineer. As a railway it has many features in common with certain ways already laid, and in actual use; but it has other features peculiar to itself. I give preference to this, because it is at once very substantial and durable, and of moderate cost; and is at the same time better fitted, (as I judge,) to avoid *unequal* and *permanent* displacement by frost, than either the wooden frame, or the cross sleepers bearing upon longitudinal trenches of broken stone,—unless with additional and expensive transverse trenches. The bearing of this railway is to be upon stone slabs of twenty inches square, or an equivalent surface, and from three and a half inches to four and a half inches in thickness. These slabs are to be embedded in the sand,—one in each lineal yard, for the whole extent under both rails. Upon the two corresponding slabs of each yard there will come down a transverse sleeper of red cedar, five inches square and seven feet long. This sleeper is to receive upon it, at each end, directly above the central bearing on the slab, a cast iron chair set into it, and secured by wood screws; which chair becomes, together with its fellows, the bed of a rolled iron edge rail, of 40 lbs. to the yard, which must be suitably secured in its place by keys. The whole body of transverse sleepers being thus three feet apart, are to be bound together by two parallel pieces of scantling, spiked on longitudinally,—one on each side of the centre; and these will also be a lateral support to the gravel which is to form the horse-path.

The following will be the cost of one lineal yard of a superstructure of this kind:

Two slabs dressed,	65 cents.
One sleeper notched,	55 "
Two chairs, 13 lbs. each,	44 "
Four wood screws,	9 "
Two yards of rail, 40 lbs. 1.79	"
Two keys and gibbs,	4 "
Scantling,	18 "
Four spikes for do.,	4 "
Setting two chairs,	8 "
Putting down work,	25 "

**\$4.10 cents.**

Cost by the yard, \$4.10 cents; or  
by the mile, \$7.216  
Say for a horse path and contingencies, 284

Cost per mile in round numbers, \$7,500

ESTIMATE FOR THE FINISHED RAILROAD.

For grading 36.64 miles for double track.	\$344,066.66
For one track laid, at \$7,500 per mile,	274,800
Turnouts,	16,000
Fencing 25 miles, at \$720, and damages,	40,000
Four locomotives and tenders, at \$6,500,	26,000
Twenty passenger carriages, at \$850,	17,000
Thirty burden cars, at \$350,	10,500
Two depots,	15,000
A carriage-house,	7,500
Engine-house and shop,	5,000
Two watering stations,	2,500
Contingencies,	30,000
Engineering and superintendence,	30,000

Cost of 36.64 miles of railroad, being per mile \$22,335.33, \$818,366.66

It will undoubtedly be necessary to form a direct connection with the steamboats to New-York, and if the expense of this be added, (as it ought to be,) the entire cost of the railroad, when ready for operation, may be stated at \$830,000, an estimate which, of course, applies only to the main road with a single track. If the company shall ever choose to construct branches, or to lay, in whole or in part, a double track, those additions will have their appropriate estimate at such time as they shall be determined on.

The sum, gentlemen, which has just been stated, may exceed, I am aware, your anticipations; and it must be admitted, that when we consider the generally favorable conditions of soil and location under which the work is to be executed, the estimate bears the appearance of a large one. But as it has been your desire to be acquainted with the exact truth, so it has been my aim to put you fully in possession of it; and I am desirous to have it understood, that in making up this amount I have kept in view the notorious fact, that the estimates of cost which have been made at the outset of almost every considerable undertaking of this kind in the United States, have been proved by the result to be far too low; and that I have intended to adjust the *standard* of this estimate so high, that the final cost of your work may not, if judiciously managed, exceed the original expectations of the stockholders. And here I would recall to your notice the general conditions of the work to which the amount above estimated is intended to apply.

The road is supposed to be put in preparation for a double track, and a single one to be laid. The prepared surface is to have a breadth of thirty feet at the level of the grade; but to provide for the contingencies that may arise in this department, the computations have been made *throughout*, in all excavations, embankments, rock, bridges, and culverts, for a breadth of thirty-five feet; and no advantage has been taken of the sometimes admissible economy of narrowing, for the present, the dimensions of deep cuts, and high embankments. These principles of computation have, doubtless, latitude enough: let us look next at the conditions under which the execution of the work is to take place.

At this part of the review we find that the line running in the direction of the ridges, will have to encounter few very untractable districts of country; that the ex-

cavation for one half of the route is of the very easiest kind, and for the other half only of ordinary difficulty; that no one very expensive bridge, or other structure, need be counted upon; that the workmanship of such incidental structures as are to be made, is supposed to be only so expensive in kind, as to insure a *substantial* and *neat* performance; and that the plan of the railway, while abundantly strong and durable, is yet one of moderate cost. Such are the grounds upon which I hold the belief, that unless a second track, in whole or in part, should be added, or branches be extended out from the main body of the road, (which, if resolved upon, must have their own estimate,) the sum of \$830,000 will complete the railroad, and put it in successful operation.

#### ANNUAL EXPENDITURE.

The expenses for the road and engines, and all contingent outlays for operations of this kind, are easily calculated from data derived from different roads in this country, that are in actual use. The annual expense of repairs may be taken at \$4,000.

The annual expense of transportation of burdens, such as cotton, manufactured articles, &c. would vary with the amount of this transportation, and the number of trips by the day which would be made. For the quantity of tonnage with which this road would open, we may consider the cost of transporting a ton from city to city, including fuel, oil, repairs, and attendance, at fifty cents the ton. For the number of passengers with which the road would open, there must be two trips and two return trips each day, which at \$15 the trip for 313 days, being the entire year, except Sundays, would make for the year, (including fuel, oil, repairs of engine and train, engine man, and all attendance,) \$18,780. The salaries of superintendence and clerks may be put at \$4,000. Supposing, therefore, the road to open with a business (in addition to the passage trips) that would be done by a single trip and return trip of a train of burden cars, carrying from twenty to thirty tons to each trip, and the same to each return trip, the entire annual outlay upon the railroad would be from \$33,000 to \$34,000.

#### Resources of the Railroad.

The amount of income which the holders of stock in this railroad may fairly count upon, is fixed, for the greater part of it, by ascertained facts; and for the rest, it must be matter, to some extent, of judgment. After carefully collating the supplies of revenue which will certainly fall into the channel of this road, and drawing cautiously upon those other currents of travel and transportation which will be within its influence, but which can fairly be counted upon only in part, I find, as the result of my own private judgment, an aggregate of annual receipts, which, after canceling the expenditures, will yield at once a fair return of interest to the stockholders. But, as this is a subject upon which every man, after having the facts before him, must be his own judge, I shall throw together, in a concise statement, the materials for forming a judgment, that are in my possession. Let me remark, however, that, if it were important for me to put down in figures my own private view of the subject, I should be far from copying after those romantic visions of per centage, in which half the projectors of useful public works throughout the world have indulged at the outset, and which have led almost of course to considerable disappointment. A judicious consideration of the subject would undoubtedly make it appear that (except in the case

of some great thoroughfares, that may be able to keep entirely aloof from competition,) the body of judicious railroads cannot, in respect of profit, range at once far above the business level of the country. But there are three considerations, which make this species of investment more desirable than an ordinary outlay. These are to be found in the *security*, the *permanence*, and the *increasing profit*, of such an investment. The estimation in which capitalists hold any investment that is both secure and permanent, even though it should yield but a moderate rate of interest, is manifest in the high customary premium upon five per cent. government stocks; and while in both these particulars, a profitable railroad stock is not inferior to a government stock, it has, in its *increasing rate of interest*, an element of value peculiar to itself.

The opinion which I have already expressed, respecting the intrinsic value of this particular railroad as a source of profit, rests upon facts which I shall now state, together with the sources, in general, from which these facts were derived.

Mr. John Babcock, general agent and proprietor of the stage lines from Hartford to New-Haven, states (as the result of actual investigation from the books) that there has been received annually, for the past five years, \$35,000 on an average; of which sum, \$5,000 was for mails. The price of passage has been \$1.50, to those coming by steamboats from New-York, who form the body of the passengers; but to those who have taken the stage at the cities, \$2. The number of passengers has therefore been 18,000 per annum; and this number corresponds with Mr. Babcock's estimate. In addition to the receipts from this source, a part of the mail money,—say \$3,000,—is to be counted on for the railroad. Also, there will be probably 2,000 of the local passengers, who now go between Hartford and New-Haven, or the intermediate towns, by private conveyance, that would, upon the construction of this work, prefer the latter.

A principal agent of the steamboat lines at Hartford, who knows the exact truth upon this subject, being applied to for information, has stated the amount of passage money taken on board the Hartford boats, at \$90,000 per annum; and he estimates the number of passengers at 30,000 annually. This estimate is thought by others, in the same line of business, to be low; indeed, if we judge from the full fare to New-York, which is \$3, that number must exclude, *in part*, those who, being way-passengers, and stopping at different places upon the river, are not to be counted upon in an estimate for the railroad.

The present number of passengers from New-York to Providence, is known to be estimated at 50,000 annually. Aside from the interposition of railroads, to vary the natural channels of intercourse, this route to Boston by Providence has been vastly superior to every other; and has taken, of course, nearly the whole long travel between the two great cities. But it is obvious, that if any other route had existed, possessing the same natural inducements, it would certainly have drawn to itself one half of the travel. If the distance from New-York to Boston is as great as it is generally taken to be, there would be, when the Hartford and New-Haven communication shall be open to Worcester, (an event which, I cannot doubt, will speedily find its accomplishment,—a charter for this railroad, as well as the Springfield road, having been already obtained to the north line of Connecticut,) a decided difference of

distance in favor of the route by Hartford. But I presume that distance to be overstated, and the distance to be, in fact, trifling; so that the times of arrival, by way of Providence, or of Hartford, will be nearly balanced. But the opening of this new route, equally advantageous with the former, will necessarily divide the travel, though in what ratio it is difficult to determine.

Besides these currents of travel, there is a great amount of passing to New-York from the north parts of Connecticut, and the south parts of Massachusetts, by the way of the Hudson river. No one can make even an *approximate* estimate of the amount which will be diverted by this railroad. When I placed it at 2,000 passengers, it was taking but one-fifth of the estimate made by others, who are as well-informed upon the subject as I am.

If, on a review of the foregoing facts, any one shall have fixed his mind upon any specific amount of travel with which the Hartford and New-Haven railroad would open at once, or any specific amount, including what would be drawn to it from other channels, as soon as the contemplated extension to Worcester shall take place, let him also consider, that his supposed number of passengers has been deduced only from the currents of travel *now* existing; and that the natural increase of activity in a region which is traversed by newly opened lines of communication, and in the country at large, may justify a greatly enlarged estimate of that number, as applying to the state of things that will exist in a few years to come. To fortify this view, let him cast an eye at the projected railroads which will centre at Hartford. First, there will be the Bolton road, which will connect, probably, with the Norwich and Willimantic railroad,—then there will be the railroad to Worcester, and that to Springfield. The railroad which is shown by the map, making off towards the Hudson river, may be considered by many a project too distant to be taken into notice here; but a petition for such a grant is even now pending, and the same connection will certainly be made through Springfield before a distant day. Of these four lines of communication, the Hartford and New-Haven railroad will be the trunk; and, through the Springfield communication, (which will certainly not terminate at the town last named,) will hereafter extend its arms into the higher parts of the Connecticut valley.

In addition to the foregoing sources of revenue, I judge from the facts before me, that the transportation of burdens upon this road will, at its first opening, be sufficient to employ at least one train of burden-cars each day, in a trip going and returning, carrying from 20 to 30 tons each way. But of this amount, and of its probable increase, some estimate may be formed from the facts which I now present.

I have received, from Elisha A. Cowles, Esq., of Meriden, a statement of the amount of transportation to Hartford and Middletown, from the villages of New-Britain, Worthington, Meriden and Wallingford, which lie on the route. This was compiled by means of a personal application to each individual named in the list. The amount is more than seven thousand tons, now transported at an expense of eighteen thousand dollars. Of this amount, two thousand tons would not pass upon the road, except in the event of a particular location, which, though as probable as any other, is not certain. I have deducted the

two thousand tons, and call the remainder equal to three thousand tons taken *through*.

The amount of transportation between Hartford and New-Haven, during the past winter, has been ascertained from the teamsters to have been three thousand tons, and the expense eighteen thousand dollars.

The Connecticut river is closed for four months in the year; and during that period, this railroad will take its place for the *whole* transportation; and during the remaining eight months, for a *part*. What the entire tonnage of the river is, has not been directly ascertained; but some light is thrown upon the subject, by the journal of the "Convention held at Windsor, Vermont, September 29 and 30th, 1830, for the purpose of taking into consideration, subjects connected with the improvement of the navigation of Connecticut river." In the report of a committee of that convention, I find, under the head of annual exports from the Connecticut river valley, the following *estimated* items: Beef, 10,181 tons; pork, lard, ham and bacon, 10,395 tons; butter and cheese, 8,050 tons; wool, about 800 tons; besides a considerable amount of other products. The imports are put, in the same estimate, at 25,000 tons. The aggregate of imports and exports in 1830, was, according to this authority, 54,426 tons, besides great quantities of lumber not here included. If these estimates are correct, it is probable, that there now comes into or passes Hartford, of both imports and exports, thirty thousand tons annually, supposing an equal amount taken off eastward by other channels.

Besides its portion of the foregoing transportation, this railroad would do a large business in winter, and a considerable business in summer, in supplying raw material to the large and numerous manufactories in Connecticut and Massachusetts, towards which it will lead, and returning to market the manufactured article. There are now at Springfield, and in the region around it, about sixty thousand spindles in operation;\* and these, I should judge, (as twenty-eight thousand of the number are stated to consume eight thousand bales of cotton,) must create a transportation, to and fro, of six or seven thousand tons; and probably this same region, when its power shall be fully taken up, will transport five times, or perhaps even ten times, its present amount. A large amount of the cotton to feed these establishments would pass on your railroad,—as the new crop does not come in till the river is about closing.

It was stated by the witnesses who testified before a committee of the Connecticut Legislature, at its last session, that the manufactories upon the Hockanum and Tan-karson, near Hartford, now transport from Hartford ten thousand tons of raw material, and return it in manufactured articles; that on the route to Worcester, there are, within the bounds of Connecticut, eight factories, besides paper mills, furnaces, and cupolas; and that out of Connecticut there are on the same route, in four or five towns, forty-five manufactories, both cotton and woollen, with an average business of one hundred thousand dollars annually. Their raw material is now received by way of Providence and Boston, and their manufactured articles returned to a southern market by the same route; but if an opening to New-Haven were created, this tonnage would fall into that new channel, both be-

\* The number of spindles here stated is more than half the number in operation at Lowell, Mass.

cause its market is south, (at N. York and Philadelphia,) and because the saving of insurance from Boston to those cities would pay a large proportion of the entire freight to New-Haven.

When, from the foregoing facts, a just estimate shall be formed respecting the business to be done at once upon this railroad, it will still need to be greatly enhanced in order to apply to the state of things a few years hence,—in accordance with the considerations which were before applied to the subject of travel, as it is now, and as it will be soon, when the railroad shall have exercised a while its power upon the business and enterprise of the whole region within its influence, and shall have spread its branches widely by means of its junction with those other roads of which it is destined to be the trunk at no distant period.

I have the honor to be, gentlemen, your obedient servant,

ALEX' R. C. TWISS,  
Engineer.

New-Haven, July 19, 1835.

We find in the Newark Daily Advertiser, the following account of something new in the way of propelling boats.

"Dr. PLANTOU, of Philadelphia, is now exhibiting at No. 93 Broadway, New-York, a model of his method of constructing and propelling steamboats, and will be happy to show and explain its principles to all who will do him the favor of a call. The principle is the propulsion of boats by means of water-tight revolving cylinders, furnished with paddles. One of these cylinders is placed at each end of the boat—and acting both as buoyancers and propellers, they effect, as the inventor very satisfactorily demonstrates, the important object of impelling the boat over the surface of the water without having to overcome the great resistance encountered by the usual method of forcing it through the water. The current created by the action of the forward cylinder, passes entirely under the boat, and by lifting it up, aids in impelling it forward.

"Dr. Plantou's models, &c. were submitted to a select committee appointed by the last Legislature of New-York, who recommended them to the favorable consideration of the canal board. The Board have since expressed their approbation of the project."

It will be seen by the following article from the  
indeed an  
the Buffalo

anal.]  
is improve-  
portance to  
which has  
d, about to  
rise. Buffa-  
ted wholly  
s being sus-  
nd as that  
or extends  
xisted, and  
is crowded  
rendering it  
. Hence it  
ely, Buffalo  
is than one

gress, and  
to augment the facilities of occupying and improv-  
ing all parts of our harbor front, we learn that a  
contract has been closed by several gentlemen,  
with Col. O. H. Diddle, for carrying out the origi-  
nal project of Joseph Elliott, Esq., thus forming  
another mouth to Buffalo Harbor. At the easter-  
ly line of our city, the Buffalo Creek approaches

to within eighty rods of the Lake shore. At this point a cut is to be made, one hundred feet in width, from the harbor to the lake of sufficient depth for navigation, and secured, at the Lake end, by a pier extending into the Lake. This entrance will be a mile or more from the present one: and by doubling the facilities of admission and departure, will largely provide for the rapidly augmenting commerce of our Lakes. The work we learn, is to be completed the ensuing season, and when done to be dedicated to the public, without any charge or incumbrance, whatever.

NEW YORK AND ERIE RAIL ROAD COMPANY.—We take great pleasure in stating, upon unquestionable authority, that this Company, by their directors, engineers and agents, have made very rapid progress during the present summer, towards completing the arrangements necessary for commencing the actual execution of this great work—and that the public may confidently expect that at least fifty miles will be put under contract during the ensuing autumn.

By inquiries actively prosecuted, under the personal inspection of some of the Directors, they have acquired increased confidence in the practicability and productiveness of the work. The Allegany river, which more properly might be denominated the Upper Ohio, is represented as affording the strongest incentives to exertion, by supplying to this city the means of a rapid, safe and cheap communication with the great line of cities and villages along the Ohio, during the whole of the early spring, and especially during the season when our commerce is obstructed by the ice on the canals and on Lake Erie.

It is believed that the company, if properly supported by the public, will be able to extend their road to this most valuable river, within five years from the present season. It is also highly gratifying to learn that the enterprising and liberal spirited inhabitants along the line, are exerting their utmost efforts to facilitate the progress of the work, not only by making and procuring gratuitous cessions of the land required for the road-way, but also by subscribing to the extent of their means, to the stock of the company. We learn, too, that the surveys made during the present summer, have still further improved the route of the road, as well in shortening the line, as diminishing its cost.—[N. Y. American.]

An Engineer at Rouen has according to the National Gazette, obtained a patent from the French Government, for a suspension bridge, with an arch sufficiently high to admit the passage under it of the highest mast.

The Gazette adds that "the draw bridge is said to be of so simple a construction, that it may be raised by one person with the greatest ease." But if the arch is so high, as to admit the passage under it of the highest mast, what use is there for a draw-bridge?

RAILROAD BETWEEN PORTLAND AND QUEBEC.—A public meeting was held in Quebec on Monday, 20th inst., to consider the proper preliminary steps to be taken in favor of this enterprise. J. W. Woolsey was in the chair, K. Fisher Secretary.—Mr. A. Smith, one of the Commissioners appointed by the State of Maine, was introduced to the meeting, and explained the views and wishes of Maine on the subject, all which tended to increase the facilities of intercourse between the United States and Canada. He was received with cheering, and resolutions were subsequently passed, asking the concurrence of the Governor of Canada, in the efforts making by Maine, and in those which the citizens of Quebec stand ready to make.

Morris Canal Collector's Office,  
NEWARK, July 27, 1835.

Arrived from the 15th to the 26th July, from Mauch Chunk, Easton, Washington, Port Colden, Stam-  
hope, Dover, and other places:

126 boats with coal—2531 8 tons  
59 do. with other articles—1009 12 tons

185 boats 3540 18 tons

Cleared during the same period:

71 boats with merchandise—1033 00 tons  
115 do. in ballast—coal boats

186 1033 00 tons

Total number of boats, amount of tonnage passed  
the lock during the above period:

371 boats—4573 tons 18 cwt.

THOMAS MCGAURAN, Collector.

CANAL STEAMBOAT.—A new steamboat called the Phenomenon, has been placed on the Erie Canal, to ply between Rochester, at which place she was wholly built, and Utica. She is so constructed that those on board can enjoy the benefits of walking on the outside, a few inches above the water, without the inconvenience of dodging a bridge every few moments. She has two commodious cabins, and is propelled at the rate of five miles an hour including lockages, by two wheels, at a moderate expense—the swell or wake is so trifling that it can be no objection to her travelling the canal.—[Sun.]

CANAL CELEBRATION.—The canal boat Northampton, with a delegation from this city, and a large number of citizens, started this morning from Hillhouse's Basin, for Northampton, in pursuance of an invitation from the citizens of that town, to celebrate the completion of the Hampshire and Hampden Canals, and their junction with the Connecticut river. The Governor of the State, Mr. Senator Smith, and other distinguished gentlemen, accompanied the party, which went off with streamers flying, a band of music, and hearts full of glorious anticipations. Success attend them!—[New Haven Herald.]

NEW FERRIES AND AVENUES.—It is with satisfaction, we observe that a new ferry to Long Island is about to be established, from the foot of 13th street, to North street in Williamsburg. The line across is almost a straight one, and the starting points on each side of the river, such as to accommodate a large population, both in the city and on Long Island. When is the contemplated ferry on the North river, from the foot of Amos street to Hoboken, to be established? It is much wanted for the accommodation of the upper part of the city.

A macadamized avenue on the west side of the city, similar to the Third avenue, so as to afford an equally convenient outlet to the residents in the 9th, 8th, 5th and 3d Wards, is also proposed, and will be, we hope, made forthwith. And this affords a fitting opportunity for repeating a question, frequently before asked in this paper, why ferries should not, equally with avenues, be established and kept up at the public expense, and free from toll? There is no distinction, that we can perceive, in principle, between facilitating access by land and access by water, to "the great city." We gain, by every obstacle removed on either element; and we do not see why—if roads are made and kept in repair out of the general funds, ferries should not in like manner be. At any rate, it certainly is inconsistent with common right, that monopolies in ferries should be created in behalf of private individuals, and that they should grow rich, enormously rich, as the lessees of the Fulton ferry have done, and are doing, out of the pockets of their fellow citizens,—every one of whom has a right—which the city of his residence ought to secure to him, as it does the lighting of the streets at night, the establishment of a watch, &c.—to go back and forth over the river, as on the road,—scot free.

We are aware that no such change can be effected during existing leases, on established ferries—but in reference to that one about to be established, from the foot of 13th street, and to the principle itself—our remarks are as well timed now as on any other occasion.—[N. Y. American.]

[From the London Penny Magazine.]

**MR. JOHN LOMBE, AND THE SILK-THROWING MACHINERY AT DERBY.**—The Lombes were originally manufacturers at Norwich, but removed to London, and became silk throwsters and merchants there. There were three brothers, Thomas, Henry, and John; the first was one of the sheriffs of London at the accession of George II. in 1727, on which occasion, according to custom, the chief magistrate was created a baronet, and Mr. Lombe was knighted. The second brother, who was of a melancholy temperament, put an end to his existence before those plans were developed which connected the name of Lombe with one of the most important manufactures of the country.

The Messrs. Lombes had a house at Leghorn under the firm of Glover & Unwin, who were their agents for purchasing the raw silk which the Italian peasantry sold at their markets and fairs to the merchants and factors. There were many other English houses at Leghorn, Turin, Ancona, and other parts of Italy, chiefly for exporting silk to England, in part return for which numerous cargoes of salt fish were and still are received from our ports for the consumption of the Italians during their Lent and other fasts. It was at that time customary for the English merchants engaged in the Italian trade to send their apprentices and sons to the Italian ports to complete their mercantile education, by acquainting themselves on the spot with the details of their peculiar line of business. It was professedly in compliance with this custom, but, with a deeper ulterior view, that the youngest of the brothers, Mr. John Lombe, who at that time was little more than twenty years of age, proceeded to Leghorn in the year 1715.

The Italians had at that time become so much superior to the English in the art of throwing silk, in consequence of a new invention, that it was impossible for the latter to bring the article into the market on equal terms. This state of the trade induced the Lombes to consider by what means they might secure the same advantage which their improved machinery gave to the Italians; and the real view of the younger brother, in proceeding to Italy, was to endeavor to obtain such an acquaintance with the machinery as might enable him to introduce it into this country. The difficulties in the way of this undertaking were very great, and would have appeared insurmountable to any but a person of extraordinary courage and perseverance. We find these difficulties thus stated in the paper which Sir Thomas Lombe printed for distribution among the members when he applied to Parliament for the renewal of his patent. One at least of these printed papers has been preserved, and has been lent us for the present occasion. It is there said, that "the Italians having, by the most judicious and proper rules and regulations, advanced and supported the credit of the manufacture, have also, by the most severe laws, preserved the mys-

tery among themselves for a great number of years, to their inestimable advantage. As, for instance, the punishment prescribed by one of their laws for those who discover, or attempt to discover, any thing relating to this art, is death, with the forfeiture of all their goods, and to be afterwards painted on the outside of the prison walls, hanging to the gallows by one foot, with an inscription denoting the name and crime of the person; there to be continued for a perpetual mark of infamy."

The young Lombe, however, was not to be deterred by the danger and difficulty of the enterprise. On his arrival, and before he became known in the country, he went, accompanied by a friend, to see the Italian silk works. This was permitted under very rigid limitations. No person was admitted except when the machinery was in action, and even then he was hurried through the rooms with the most jealous precaution. The celerity of the machinery rendered it impossible for Mr. Lombe to comprehend all the dependencies and first springs of so extensive and complicated a work. He went with different persons in various habits, as a gentleman, a priest, or a lady, and he was very generous with his money; but he could never find an opportunity of seeing the machinery put in motion, or of giving to it that careful attention which his object required. Despairing of obtaining adequate information from such cursory inspection as he was thus enabled to give, he bethought himself of associating with the clergy, and being a man of letters, he succeeded in ingratiating himself with the priest who confessed the family to which the works belonged. He seems to have opened his plans, partly at least, to this person, and it is certain that he found means to obtain his co-operation. According to the scheme which they planned between them, Mr. Lombe disguised himself as a poor youth in want of employment. The priest then introduced him to the directors of the works, and gave him a good character for honesty and diligence, and described him as inured to greater hardships than might be expected from his appearance. He was accordingly engaged as a fillatoy-boy, to superintend a spinning engine so called. His mean appearance procured him accommodation in the place which his design made the most acceptable to him,—the mill. While others slept, he was awake, and diligently employed in his arduous and dangerous undertaking. He had possessed himself of a dark lantern, tinder box, wax candles, and a case of mathematical instruments: in the day time these were secreted in the hole under the stairs where he used to sleep; and no person ever indicated the least curiosity to ascertain the extent of the possessions of so mean a lad. He thus went on making drawings of every part of this grand and useful machinery; the priest often inquired after his poor boy at the works, and through his agency Lombe conveyed his drawings to Glover and Unwin; with them models were made from the draw-

ings, and dispatched to England piecemeal in bales of silk. These originals are still, we believe, preserved in the Derby mills.

After Lombe had completed his design, he still remained at the mill, waiting until an English ship should be on the point of sailing for England. When this happened, he left the works and hastened on board. But meanwhile his absence had occasioned suspicion, and an Italian brig was dispatched in pursuit; but the English vessel happily proved the better sailer of the two, and escaped. It is said that the priest was put to the torture; but the correspondent of the "Gentleman's Magazine," to which we are indebted for most of the facts we have stated, says that after Mr. Lombe's return to England, an Italian priest was much in his company; and he is of opinion that this was either the priest in question, or at least another confederate in the same affair. Mr. Lombe also brought over with him two natives accustomed to the manufacture, for the sake of introducing which he had incurred so much hazard.

After his return Mr. John Lombe appears to have actively exerted himself in forwarding the works undertaken by him and his brother, Sir Thomas, at Derby; but he did not live to witness their completion. He died on the premises, on the 16th of November, 1722, in the 20th year of his age. The common account of his death is, that the Italians, exasperated at the injury done to their trade, sent over to England an artful woman, who associated with the parties in the character of a friend; and having gained over one of the natives who originally accompanied Mr. Lombe, administered a poison to him of which he ultimately died.

We recur to Sir Thomas Lombe's statement, already quoted for the most authentic particulars respecting the progress of the work. The document itself is entitled, "A Brief State of the Case relating to the machine erected at Derby, for making Italian Organzine Silk, which was discovered and brought into England with the utmost difficulty and hazard, and at the sole expense of Sir Thos. Lombe." It commences with stating the capabilities of the machine. "This machine performs the work of making Italian organzine silk, which is a manufacture made out of fine raw silk, by reducing it to a hard twisted, fine, and even thread. This silk makes the warp, and is absolutely necessary to mix with and cover the Turkey and other coarser silks thrown here, which are used for shute; so that without a constant supply of this fine Italian organzine silk, very little of the said Turkey and other silks could be used, nor could the silk-weaving trade be carried on in England. This Italian organzine (or thrown) silk has in all times past been bought with our money, ready made (or worked) in Italy, for want of the art of making it here; whereas now, by working it ourselves out of fine Italian raw silk, the nation saves nearly one third part; and by what we make out of fine

China raw silk, above one half of the price we pay for it ready worked in Italy."

The paper goes on to state, that "the machine at Derby has 97,746 wheels, movements, and individual parts, (which work day and night,) all which receive their motion from one large water wheel, and are governed by one regulator; and it employs 300 persons to attend and supply it with work." After stating the difficulties which had been surmounted in introducing this improvement, the paper thus concludes: "Upon the introduction of which [this improvement], his late most gracious Majesty granted a patent to the said Sir Thomas Lombe, for the sole making and use of the said engines in England, for the term of fourteen years. Upon which he set about the work and raised a large pile of building upon the river Derwent at Derby, and therein erected the said machine; but before the whole could be completed, several years of the said term were expired. Then the King of Sardinia, in whose country we buy the greater part of our supply of organzine silk, being informed of his success, prohibited the exportation of Piedmontese raw silk; so that before the said Sir Thos. Lombe could provide a full supply of other raw silk proper for his purpose, alter his engine, train up a sufficient number of work-folk, and bring the manufacture to perfection, almost the whole of the said fourteen years were run out. Therefore, as he has not hitherto received the intended benefit of the aforesaid patent, and in consideration of the extraordinary nature of his undertaking, the very great expense, hazard, and difficulty, he has undergone, as well as the advantage he has hereby procured to the nation at his own expense, the said Sir Thomas Lombe humbly hopes the parliament will grant him a further term for the sole making and using his engines, or such other recompense as in their great wisdom shall seem meet."

The Parliament considering the matter of much public importance, thought it best to give him a grant of £14,000, on condition that the invention should be thrown open to the trade, and that a model of the machine should be deposited in the Tower of London for public inspection. It is commonly stated that Parliament refused to extend the patent, and granted the money to soften their refusal; but we have seen that Sir Thomas himself suggested some "other recompense" than an extended patent as an alternative. In the course of time similar mills began to be erected in different parts of the country; but in consequence of the difficulties that were experienced in procuring Italian raw silk of the proper size for organzine, (the exportation of which was prohibited by the Italians,) and also because the mills happened subsequently to find employment for other purposes, the quantity worked into organzine, in this country, bore for many years no proportion to the imports from Italy. The manufacture has, however, been since revived and improved. In consequence of which it is now car-

ried on to a very considerable extent, not only in Derby, but in other parts of the country.

The mill erected by Sir Thos. Lombe stands upon an island, or rather swamp, in the Derwent, about 500 feet long and 52 wide. The building stands upon huge piles of oak, double planked, and covered with stone-work, on which are turned thirteen stone arches, that sustain the walls. Its length is 110 feet, its breadth 39, and its height 55 feet. It contains five stories. In the three upper are the Italian winding engines, which are placed in a regular manner across the apartments, and furnished with many thousand swifts and spindles, and engines for working them. In the two lower floors are the spinning and twist mills, which are all of a circular form, and are turned by upright shafts passing through their centres and communicating with shafts from the water wheel. The spinning mills are eight in number, and give motion to upwards of 25,000 reel-bobbins, and nearly 3000 star-wheels belonging to the reels. Each of the four twist mills contains four rounds of spindles, about 389 of which are connected with each mill, as well as numerous reels, bobbins, star-wheels, &c. The whole of this elaborate machine, though distributed through so many apartments, is put in motion by a single water wheel, twenty-three feet in diameter, situated on the west side of the building. All the operations, from winding the raw silk to organizing or preparing it for the weavers, are performed here. The raw silk is chiefly brought in skeins or hanks from China and Piedmont. The skein is, in the first instance, placed on a hexagonal wheel, or swift, and the filaments which compose it are regularly wound off upon a small cylindrical block of wood, or bobbin. It is the work of five or six days to wind a single skein, though the machine be kept in motion for ten hours daily, on account of the amazing fineness of the filaments of which it consists. The silk, when thus wound off upon the bobbins, is afterwards twisted by other parts of the machinery, and is then sent to the *doublers*, who are chiefly women stationed in a detached building. Here four, seven, or ten threads, are twisted into one, according to its intended size, the fine kind going to the stocking weavers, and the others to different manufacturers. Other mills erected more recently at Derby, on a similar principle, greatly surpass this in their machinery, and efficiency; but the old mill must continue to be regarded with peculiar interest, as the first establishment of the kind erected in this country.

**MINERAL KINGDOM. Gold.**—This metal possesses above all others the qualities of utility and beauty, without any deleterious property. It has been in all times regarded as the most perfect and most precious of the metals, and among the more civilized nations has been the standard of value for other commodities. Its peculiar rich hue is well known; and it is the only metal of a yellow color. In its pure state it is as

soft as tin, and is very flexible, but it is capable of receiving a high lustre by polishing with a burnisher, although inferior in brilliancy to steel, silver, and mercury. It possesses little elasticity or sonorousness. Its specific gravity is 19.30—that is, it is more than nineteen times heavier than water, bulk for bulk. In *malleability* it exceeds all other metals; for one grain of it can be beat out into a leaf so thin as not to exceed  $\frac{1}{1000}$ th part of an inch in thickness, and which will cover fifty-six square inches; in this state, notwithstanding the high specific gravity, it will float in the air like a feather. But even that is not the extreme limit to which it is capable of being extended; for a coating of gold, which is calculated to be only one-twelfth part of the above thickness, is produced by another process: if a silver wire be covered with gold, it may be drawn out into wire of still greater fineness, and retain a coating of gold; and one grain of gold will in this way coat a surface of wire about two miles and three-quarters in length. In *ductility* it also exceeds all other metals; that is, it can be drawn into finer wire than any other. In *tenacity*, however, it is greatly inferior, standing only fifth in order, in respect of that property when compared with other metals: a wire  $\frac{1}{16}$ th of an inch in thickness will not support a greater weight than 150 lbs., whereas iron wire of the same diameter will sustain a weight of 550 lbs. without breaking. It is not a perfectly opaque body like all the other metals, for gold leaf transmits a green light; as may be conveniently observed by laying a leaf between two thin plates of colorless glass, and holding it between the eye and a strong light. It is less fusible than silver, and more so than copper: Mr. Daniel estimates its melting point to be at a heat equal to 2016° of Fahrenheit's scale. It is the most perfect of all conductors of heat; that is to say, if heat be applied to one end of a rod of gold, it will be transmitted from particle to particle, and become sensible at the other extremity of the rod more quickly than through any other substance in nature. Thus while the conducting power of a rod of porcelain is represented by a velocity of 12, of lead by 179, of iron by 374, the velocity of gold is 1000. Gold may be exposed for ages to air and moisture without undergoing any alteration; and a quantity of it has been kept for thirty weeks in a melted state in a glass-house furnace without the loss of a single grain, and without any change in its nature. But if a small portion of it be intensely heated by electricity, or by the oxy-hydrogen blow-pipe, it burns with a greenish blue flame, and is dissipated in the form of a purple powder.

Gold is found, almost universally, in the native or metallic state; but it is seldom quite pure, being generally alloyed, in greater or less degree, with other metals, and usually with silver, copper, or iron. The Prussian chemist, Klaproth, found a native gold from the Altai Mountains to contain as much as 36 per cent. of silver; and Professor G. Rose, of Berlin, by more recent analysis, has found a specimen from the same district to contain 38 per cent., and another from Hungary nearly 39 per cent. He found the gold of the Ural Mountains to contain from 2 to 15 per cent. in general; but one variety so free from foreign admixture as to contain nearly 99 per cent. of pure gold. Boussingault has found the native gold of Colombia to contain from 2 to 36 per cent. of silver. It is found in veins in the primary and older sedimentary rocks, and also in the unstratified rocks that are associated with these, such as granite,

porphyry, and hornblende rock; and sometimes, also, in the more ancient of the secondary strata. The veinstone in which the gold occurs is most generally quartz. In Transylvania small quantities of an ore have been found, in which gold is in combination with a considerable proportion of the rare metal *Tellurium*; and there is a kind of iron pyrites—that is, a sulphuret of iron,—not of very unfrequent occurrence, which contains minute scales of pure gold interposed between the laminae of the pyrites. When gold occurs in veins in solid rocks, it is sometimes regularly crystallized. In the splendid collection of minerals belonging to the Russian noble, Prince Demidoff, there are many beautiful crystals of gold from the Ural Mountains. By far the greatest proportion of this metal, in all countries which produce it, is obtained from alluvial soils, or deposits, where the gold is found in scales, grains, and lumps, rounded by attrition: so that the metal has evidently been derived from pre-existing rocks, in which it was disseminated either in minute scales or veins, and which have been broken up; the fragments having been abraded by the action of water in the same manner as the pebbles of tin-stone in the stream-works of Cornwall, and other places. For the sake of convenience, we shall call this “*stream-gold*.” It is found in the sand and gravel of the beds of many rivers and smaller streams in most countries of the world; but the chief quantity is met with in extensive alluvial deposits, formed by other aqueous causes than the water of existing rivers. The lumps of gold, in such situations, are of very various sizes; and masses have been found in the Ural Mountains of eighteen and twenty pounds weight,—in Colombia, of twenty-five pounds; and one is said to have been found near La Paz, in Peru, of nearly forty-five pounds weight, the value of which, if estimated at \$1. 10s. per ounce, would be 18900. A considerable portion of stream-gold appears to have been derived from auriferous pyrites; for almost all the sands from which this metal is gathered are of a deep blackish-brown color, and are highly ferruginous. It is a remarkable and not a very explicable circumstance that, in countries which contain deposits of alluvium rich in gold, and the materials of which must have been derived from rocks at no very great distance, it has rarely happened that the attempts to find the metal in the neighboring rocks have been successful. It may be asked, how gold comes to be so often found in alluvial soils, and that other metals should not be met with in the same way? Platinum is so found, and so is silver, but only very rarely. The reason is, that the ores of other metals are liable to decomposition by exposure to air and moisture; and, therefore, although they might have been originally in fragments, like the other materials of the rocks that were broken up, they would gradually disappear by decomposition; whereas the gold, from its indestructible nature, remains unchanged, except in form. In the same way stream-tin has been preserved, because the oxide of tin is not affected by air and moisture.

To describe the methods employed to separate gold from the other minerals with which it is combined would lead us into somewhat tedious details. The great value of gold makes searching after minute quantities profitable, which would never be practised with other metals. The usual mode of separation is by a process called *amalgamation*, which is founded on the property which mercury (or quicksilver)

has of combining very readily with gold, and of being easily separated from it again by the application of heat. The etymology of the word is Greek, viz., *ama*, together, and *gameo*, to marry; expressive in this way of the union of the gold with the quicksilver. Amalgamation is effected in this manner: the ore, broken to pieces and freed as much as possible from stony impurities, is reduced to powder, and made up into a paste with salt and water. Quicksilver in proper proportion is added, and the whole is well beaten and shaken together, and kept at the temperature of boiling water for some days, till the union is effected; after which the earthy matter is washed away, and the residue is subjected to distillation, by which the quicksilver is separated, and at the same time recovered in great part, and the gold, usually containing a little silver, is left behind. This is the usual process followed in Mexico and South America. In Hungary the gold is generally purified by another process, called *cupellation*. This depends on the property which lead and copper, the metals with which the gold is there mixed in the ores, have of attracting oxygen from the air when exposed to a strong heat, and which the gold does not. The ores are well roasted, to drive off the sulphur they usually contain, and are fused in several successive operations. The metallic mixture, freed from stony matter thus obtained, is put into a vessel made of bone-ashes, called a *cupel*; it is made of that material because it forms a porous texture, and is, at the same time, very refractory in the fire. A strong blast of intensely-heated air is now made to pass over the metal in a state of fusion, and the lead and copper becoming oxidated, are absorbed by the cupel, or skimmed off, and the gold is left behind. The lead is the great agent, for its oxide is easily fusible into a glassy substance, which sinks into the cupel, carrying the other impurities along with it; so that if the ore does not naturally contain much lead, a portion is added. We have described these processes only very generally: there are many delicate manipulations in the mode of conducting them, upon which success in the result greatly depends.

In our next section we shall proceed to describe the principal sources from which gold is derived. The ‘*Historical Inquiry into the Production and Consumption of the Precious Metals*,’ by William Jacob, Esq., may be consulted with advantage by those who are desirous of minute information; and we have ourselves relied upon it for many of the facts contained in the following sections.

#### SILVERSMITH'S PORTABLE FORGE.—

We were much pleased with the examination, at the machine shop of Mr. G. N. Miner, No. 30 Gold street, of a *Portable Forge* for the use of jewellers and others who require a small manageable fire. It consists, first, of a cast iron fireplace, much resembling a Franklin stove, with a pot, about the size and shape of the crown of an old-fashioned quaker hat, inverted, and attached to the bottom of the hearth of the stove, into which is inserted a tin air pipe, leading from the bellows, contained in a box of 37 inches long, 24 inches wide, and 16 inches deep, upon the top of which the forge or stove stands, occupying very little space, and it may be moved by one man to any part of the shop. The bellows is put in motion by the foot of the man who uses

the forge. This very convenient apparatus was invented, we are informed, by Mr. —, of Peekskill, Westchester county, New-York, and one of them may be examined at No. 30 Gold street, to which we would call attention.

**SPEEDWELL IRON WORKS.**—Speedwell is a small village situated on the Whippany river, about one mile from the pleasant town of Morris, Morris county, N. J., and celebrated for its manufactories of machinery. Located as it is in the very heart of an iron region, and supplied with an unfailing water power, it has advantages for the making of machinery which few works possess. They have been in operation thirty years, and have acquired, from the superior quality of the work, in strength, durability, and finish, extensive patronage and celebrity. The enterprising and intelligent proprietors, S. VAIL & SON, having gradually enlarged the works from their commencement, and improved the machinery as the times demanded, have spared no pains in providing the manufactories with every kind of apparatus which is necessary for the execution of the most difficult pieces of work, and with the greatest care and dispatch. At present the works consist of several shops, in which machinery in its various stages is made. The first is the forging department, where, by peculiar facilities and helps, afforded by the locality of the establishment, its water power, driving a trip hammer and also a pair of bellows, supplying all the fires with wind, its cranes and railways, is made the heaviest and most unyielding pieces of machinery. The next branch is its finishing departments, which are three. Every advantage is also here taken of its water power, and its apparatus for finishing is simple and effective. It has also a brass-foundry, and an iron-foundry erecting, a factory for spinning cotton not yet finished, a sash factory in full operation, where the mortices, tenons, &c. are made by machinery, and a saw-mill. The village is quite romantic, and its scenery enchanting—surrounded on every side by steep and high hills, overlooking the busy scenes below, and the spacious lake which spreads before the eye in beauty, embosomed between two large hills, whose verdant and woody sides slope to the water's edge.

#### Visit to the Messrs. Reynolds' Establishment at Kinderhook, New-York.

To the Editor of the *Mechanics' Magazine*:

Sir,—As my entire mental constitution is so completely tuned, and adapted to mechanical operations, that I should almost take pleasure in being ground up in any establishment which consisted chiefly of machinery, you would naturally expect to find me visiting and reconnoitring and examining and philosophizing upon, in mass and in detail, every mechanical, and especially every machine using establishment, which comes in my way; or rather which I come in the way of, even if I have to go considerably out of my way to do it.

In one of these reconnoitring excursions, which I lately made to that part of the town of Kinderhook, distinguished in the Golden Knickerbocker day by the cognomen of Valatie, partly to examine the progress of mechanical improvements there and partly to visit my friends, the Reynoldses, of that place—for I scarcely need tell you that every man who excels in nice mechanical operations is my friend, or, at any rate, I am his—I saw some improvements which I think ought to be duly noticed in your useful Magazine.

But before going into the detail of of those improvements, I hope my said friends will pardon the liberty I take, in offering you some remarks on the persons by whom the improvements have been made. They are three brothers, who appear, at least to me, to possess in an uncommon share that kind of native intellect which, when properly cultivated, becomes what is commonly called mechanical ingenuity. They are yet in early life, and have served regular apprenticeships at those branches of business, which, when combined together, embrace all the operations of machine making. They are united together, not only by the strongest tie of consanguinity, but by a congeniality of mind rarely to be met with in three members of the same family. They have, from the earliest periods of their apprenticeships, devoted their leisure hours industriously to the acquirement of such branches of science as might aid them in future business; and the joint result of their studies amounts, I should think, to a stock of mechanical science, perhaps not surpassed, if equalled, in any other establishment of the kind in this country. As their seasons for study must have been limited, it would seem they have so managed their subjects that, whenever one is at a loss, another is ready to prompt him. By the joint avails of their industry, previously to their uniting, they had acquired the pecuniary means of procuring an excellent water privilege, erecting shops, &c., to make a very respectable beginning. Every article in their shops exhibits a degree of skill in plan and arrangement, and of taste and neatness of workmanship, which are of the highest order. I am confident the most competent judge would, upon critical examination, pronounce their establishment an honor to themselves and the country.

But to return to the improvements.

The first which attracted my notice is a saw-mill, on a scale about half the size of the common saw-mill, but which may be as suitably applied to use on one scale as another. I think any person with a mechanical eye, who sees it, will concede that the propelling power necessary for a saw-mill of the common form and size, with one saw, would on this plan drive four of the same size. I will endeavor to give you a brief description, together with a diagram, which will, I think, make it clearly understood.

The saws are held and operated by

two balance beams or walking beams, similar to those used in the common steam engine. These beams are placed horizontally one above the other, exactly parallel, and their distance from each other about twice the length of the saw, more or less. Each beam is supported in the middle by a strong fulcrum or axis, resting on its pivots or bearings; which pivots or bearings are supported in the following manner.

The bearings of the lower axis rest upon strong side timbers of an oblong frame, about half way from the bottom to top, which frame is to sustain on its top the carriage and log or other timber to be sawed, with the necessary apparatus and fixtures for fastening the log, and moving it forward against the saw.

The axis of the upper beam is supported in proper boxes in two hangers or timbers, projecting downward from the framework of the building above, and must of course be securely braced.

On each end of each of these beams is a segment of a circle, the radius of which is exactly half the length of the beams; and each segment will contain about 70 or 80 degrees of a circle, more or less. Each segment has a flat steel spring, about the length of the periphery of the segment, and as wide as the thickness of the same, and the thickness of the springs about one-third or one-half that of the saw. One end of each of these springs is attached to the outer end of one of the segments, that is, to the lower end of the lower segments and to the upper end of the upper segments. The faces of the segments being made smooth, the springs will, of course, when bent to them, lie flat.

It will be readily perceived, that if the inner or approximate ends of the springs at each end of each beam, that is, a top spring and a bottom spring at each end of the beams, were connected together, in any manner so as to draw them tight, and the beams were, at the same time, placed in a parallel and horizontal position, the string, or whatever connected the top and bottom beams, with their respective springs, together, would make part of a tangent line from the centre of one segment to the centre of the other. When the beams are thus placed, if the ends are moved alternately up and down, the lines of connection between the top and bottom beams and segments will move exactly up and down, without any lateral motion whatever. If, then, these two connecting lines consist of two saws, attached to the aforesaid springs, the saws will move up and down as accurately as if carried up and down with a saw-gate, and perhaps more so. And if the power of a crank motion be applied to the centre end of either of the segments, both saws will be put in operation, one going up as the other goes down, and *vice versa*.

These saws may stand with their teeth in any direction, either to cut parallel with the beams or at right or any other angle. We have then two complete saw-mills, operated by the same power

which would operate one; and a gang of any number of saws may be operated in the same manner. If, however, the saws are set so as to cut parallel with the beams, one saw will interfere with the other; it will be necessary therefore to have the saws cut at right angles with the beams, and then, of course, the two logs can move parallel with each other.

By this plan, the weight necessarily moved up and down with the saws will be but a small part of the weight of the common saw-gate, and one saw completely balances the other, so that the power of a child will give the saws the necessary motion, except the resistance produced by cutting.

As the moving the log and other subservient operations may be effected as in the common saw-mill, no description is therefore necessary. The diagram will show the mode of hanging and operating the saw, which forms the basis of the improvement.

Several other improvements found in the same establishment will be noticed hereafter.

S. B.

[From the London Mechanics' Magazine.]

#### STEREOTYPE SUBSTITUTES.

SIR,—A writer in your Monthly Part for January, alludes to the probability of an invention by which the letters may be transferred from printed books to a kind of stereotype plates, by which copies may be infinitely multiplied, without a new composition or re-setting of types. Chemistry will no doubt add this to the numerous obligations it has already conferred upon the world; and the printing once transferred, the Chinese, or indeed the lithographic printing, may satisfy us, that the letters will be sufficiently in relief. The letter of your correspondent has suggested to me a question, whether lithography does not already supply us with a cheap mode of preserving a fac-simile copy of any types which have once appeared in the page of the printing compositor? What objection would there be to keep a copy of any printed page on transfer paper? Letter-press printing has long been successfully transferred to the lithographic stone, and if the copy taken off on transfer paper would keep for any length of time, we might, at very trifling expense, produce a few copies of a work, whenever they were wanted. I hope some of your scientific readers, who have made chemistry their study, will be so obliging as to solve this question: whether a copy made on transfer paper will keep for any length of time without being decomposed? In many cases the benefit to the literary world would be very great, from having the means of keeping (and renewing) a copy of a printed page, for immediate use, as type, in a space scarcely greater than that occupied by a printed book, and from it to have the power of producing copies, at an expense not worth any consideration, when compared with the cost of re-setting the press. I am, &c. B. B.

NEW-YORK AMERICAN.

JULY 25-31, 1835

LITERARY NOTICES.

**ANNE GREY.** A Novel. Edited by the author of *Grandy*. 2 vols. CAREY, LEA & BLANCHARD. —An agreeable and sprightly novel—evidently and unmistakably from a female pen, and developing, in the person of the heroine, ANNE GREY, one of the sweetest female characters imaginable—a character, not of striking contrasts, nor of any of the ordinary marvellous qualities of professed heroines, but such, as a fine temper, good example, and a well cultivated heart, as well as understanding, may contribute to form at any time. The cousin's character, however—though necessary to the story, which could not get along without her evil machinations—is an incredible exaggeration.

**THE GIFT,** a Tale by the author of *Richelieu, Mary of Burgundy, &c.*, 2 vols. New York, HARPER & BROTHERS.—To say that this is a tale of power, is only what might be expected, after designating the author; but to say that it will add to the fame of him who wrote *Richelieu*, and *Mary of Burgundy*, is what our literary conscience will not permit us to do. We were disappointed in the work—both as to interest and execution—there is too much diffuseness, too decided a purpose to spin it out, to the required number of pages, and to cram the ever craving maw that cries "copy, copy, more copy." But it is, nevertheless, a tale that will be read.

**THE LIFE OF EDMOND KEAN;** 1 vol., New York, HARPER & BROTHERS.—A player's life should, on the Shakespearian dictum that "all the world's a stage," be a sort of epitome of humanity under all its varying phases. And so we suppose it is—at any rate the biographies or personal memoirs of players, when executed with any degree of talent, have always been popular reading.

The author of this book—though it appears anonymously, is stated to be *Barry Cornwall*.—Whoever he be, he has executed his task in an attractive manner, and one removed, in the farthest degree possible, from that of mere book-making—for, doubtless, the materials under his hands, but for judicious compression, might easily have been swelled to volumes as thick and dull, as *Boaden's Life of Kemble*.

**THE GENTLEMAN'S POCKET FARRIER, &c. &c.** By F. TUFFNELL. N. Y.—Office of the *N. York Farmer*, and T. & C. WOOD.—We like this convenient little manual. It goes into the pocket, and has, as it seems to us, receipts—and we dare say they are good ones, since they are said to be founded on many years' experience—for all the accidents of lameness, galls, &c. to which horses are liable on a journey.

[From the *London Athenæum*, of June 13th.]

Personal Recollections of the late Mrs. Hemans.\*

There are few cases in which delicacy and feeling are more entirely tested, than when the surviving friends of those who were gifted and celebrated while on earth, are called upon to determine in

\* Perhaps this is a proper place to advert to a correction of a fact in our obituary notice of Mrs. Hemans, which has appeared, it is said, on authority, in the *Liverpool Standard*. She is there stated to have been born in Duke street, and not in St. Anne street. As an exact fact thus published, we can have no hesitation in submitting to correction. The same paragraph, however, contains a notice of her domestic life, equally ill-considered and incorrect: it is all wrong, both to the dead and the living, to mistake occurrences, about which there can be no mistake.

what time and in what measure some account may be offered to the public of their personal history and private character. Such, at least, is my feelings, in attempting to collect my remembrances of my deceased friend, Mrs. Hemans. I am afraid of saying too much, lest I be thought premature and unfeeling, in thus minutely dwelling upon the manners and habits of one scarcely cold in her grave. I am afraid of saying too little, lest those who knew her less, should think it requisite to complete the picture, by additions which bear little resemblance to the original. Had I merely consulted my own inclinations, the following notices would have been deferred some time; for who is there that can turn over the pages of his memory to seek for relics and memorials for those who have recently passed away, without a feeling of disinclination to produce such feelings, to the gaze and criticism of the public?

When I first became acquainted with Mrs. Hemans, her fame was at its brightest, and her lyrics published in the different periodicals—her 'Forest Sanctuary,' and above all her 'Records of Woman,' (probably from the happy choice of its subjects) had not only raised her name high in the estimation of all classes of readers, but had excited considerable curiosity, and I really believe genuine interest, as to the person and fortunes of the writer. She was, however, unknown, save to a small and select circle of friends—some spoke of her as an old and experienced verse-wright, some, remembering her juvenile poems, and forgetting that Time had since been at work for some fifteen years or more, described her as still very young and very beautiful—she was almost canonized by the serious; her claim to something more than ephemeral reputation of a young lady writer, was admitted by stern critics; in short, within two years,—dating from the publication of her 'Seige of Valencia,'—she had taken a permanent place in the republic of letters; and it was natural that the world, always preferring the peep behind the curtain, to the finest acted nature before it, should express great anxiety and solicitude to know "what she was like."

At this time, then, the death of her mother, and the marriage of her sister, were the cause of Mrs. Hemans' breaking up her establishment in Wales, and taking up her residence at Wavertree, a pleasant village about three miles from Liverpool. She had made choice of this situation for her sons, and cultivated society for herself. But the mistake she made in thus choosing, was a great one; Liverpool was then singularly deficient in good schools, and its society was too much broken up into small circles, too completely under the dominion of a money aristocracy, to offer much that was congenial to her own tastes and pursuits. She was too imaginative and fanciful to be thoroughly understood by that party to which Roscoe and Currie had formerly belonged; they found that the brilliant things which she threw out, the spontaneous overthrows of her peculiar mind, "proved nothing; and they did not perceive the elevation of thought, and the frequent religious feeling which also formed a part of her character. The less intelligent, who discovered that she did not enjoy dinners, balls, and concerts, after their fashion—and there is no code so arbitrary as the statute of manners in a provincial town—who remarked one or two singularities in her dress, and were frightened by her allusions to things and feelings of which they knew nothing, kept aloof from her, with suspicion and uneasiness.

I mention these things, neither in reproach nor derision—they are the natural and inevitable conditions of a society so constituted as the society of Liverpool—but simply as accounting for the manner in which Mrs. Hemans held herself in comparative retirement, and confined her intercourse (willingly given) to a very few. She had never learned the failings and prettinesses of the world's manners; nor, on the other hand, did she find it agreeable always to sit upon her throne, as it were, with her book of magic upon her knee, and her conjuring wand in her outstretched arm. Her humor was sprightly and searching, as well as original; she could talk delicious nonsense, as well as inspired sense; and the utilitarian and the serious, who would fain have had a moral placard and paraded upon every chance phrase of conversation, "wondered and went their way." At this time she was sought out in her retreat by every species of literary homage, from every corner of England and America; gifts, offers of service, letters of introduction crowded upon her:—literary engagements were pressed upon her, from the divinity

treatise to the fairy tale, which she simply evaded by pursuing her own way; and yet she was never so delightful, never so happy, as when she could come in, like an inmate, to the firesides of the few who understood her—at times making most pleasant merriment of the notoriety of her lot; at times, when graver subjects were touched upon, rising to a lofty and glowing eloquence, which I have seldom heard reached, certainly never surpassed.

The house which Mrs. Hemans occupied was too small to deserve the name; the third of a cluster or row, close to a dusty road—and yet too townish in appearance and situation to be called a cottage. It was set in a small court, and within was gloomy and comfortless; its parlors being little larger than closets: and yet she threw something of her own spirit round her, even in so unpromising an abode,—and with her books, and her harp, and the flowers which sometimes half filled her little rooms, they presently assumed a habitable, almost an elegant appearance. Sometimes, indeed, the scene was varied by odd presents, literary and others. I remember once paying her a visit, when a persevering writer, personally unknown to her, had sent her a hundred sonnets, printed on separate slips of paper, for inspection and approval; these had not yet been consigned to the "chaos drawer," as she used to call it, from which many a precious piece of folly and flattery might have been disinterred for the amusement of the public; and as the day was windy, and the window chanced to be open, this century of choice things, was flying hither and thither, much to our amusement—a miniature snow storm, chased by her boys with as much glee as if they had been butterfly hunting. Scarcely had she settled herself at Wavertree, than she was besieged by visitors, to a number positively bewildering; a more heterogeneous company cannot be imagined. Many came merely to stare at the strange poetess,—others to pay proper neighborly morning calls, and these were surprised to find that she was not ready with an answer, when the talk was of housekeeping and like matters. Others, and these were the worst, brought in their hands small cargoes of cut-and-dry compliments, and as she used to declare, had primed themselves for their visit by getting up a certain number of her poems. Small satisfaction had they in their visits; they found a lady neither short nor tall; though far from middle age, no longer youthful or beautiful in her appearance, (her hair, however, of the true auburn tinge, was as silken, and as profuse and curling as it had ever been;) with manners quiet and refined, a little reserved and uncommunicative, one, too, who lent no ear to the news of the day—

Who gave the ball, and paid the visit last.

The ladies, however, when they went away, had to tell: that her room was in a sad litter with books and papers, that the strings of her harp were half of them broken, and that she wore a veil on her head like no one else. Nor did the gentlemen make much way by their Della Cruscan admiration; in fact, the stock of compliment, once being exhausted, there remained nothing to be said on either side: though there were none more frankly delighted, or more keenly sensible of the genuine pleasure she gave by her writings than Mrs. Hemans. Her works were a part of herself, herself of them; and those who enjoyed and understood the one, enjoyed and understood the other, and made their way at once to her heart. I must not forget to allude to what Charles Lamb calls the "albumen persecution" which she was called upon to endure. People not only brought their own books, but those of "sister and my sister's child," all anxious to have something written on purpose for themselves. One gentleman, a total stranger to her, beset her before (as the housewives say) "she was fairly settled," with a huge virgin folio splendidly bound: which he had bought on purpose "that she might open it with one of her exquisite poems." On the whole she bore her honors meekly, and for a while in the natural kindness of her heart, gave way to the current, wishing to oblige every one. Sometimes, however, her sense of the whimsical would break out; sometimes it was provoked by the thorough-going and coarse perseverance of the intruders, against which it was difficult to guard. What could be done with persons who called thrice in one morning, and refused to take their final departure till they were told "when Mrs. Hemans would be at home?" It was on one of these occasions, that she commissioned a friend

others, in a lovely noth, to procure her "a dragon to be kept in her court-yard." At another time (and that I well remember was a flagrant case,) her vexation worked itself off in a no less cheerful manner:

"They had an album with them, absolutely an album! You had scarcely left me to my fate—oh! how you laughed the moment you were free!—when the little woman with the inquisitorial eyes, informed me that the tall woman with the superior understanding—Heaven save the mark!—was ambitious of possessing my autograph—and but leaped in lightning forth—the album. A most evangelical and edifying book it is truly; so I, out of pure spleen, mean to insert in it something as strongly savoring of the Pagan miscellany as I dare. Oh! the pleasures of fame! Oh! that I were but a little girl in the top of the elm tree again! Your which enduring F. H."

I cannot give this, and the following fragments selected from a mass of correspondence, with the different members of a family circle, without simply desiring the reader to remember that all of them were notes written—for such was her nature—from the impulse of the moment, during a period of unbroken intercourse and confidence. The graver as well as the gayer passages they contain, are so entirely characteristic, that I have not thought it right to withhold them altogether; though some may be so wound up with the less important personal interests and feelings of those whom she addressed, as not to be separable from them. All that was possible, however, has been detached, and, in so doing, I have sacrificed, with regret, much that is brilliant and striking, and speaks of and to the heart.

Besides all these home troubles, were the visits of strangers, not "angels' visits, few and far between"—from east and west, and north and south, they came—not a few from America. The admiration entertained by the Americans for her genius as sincere as it is creditable to themselves. I remember seeing a beautiful girl from New York town, quite pale with excitement at the thoughts of being presented to the poetess. "Her friends at home," she said, "would think so much of her, if she could only say she had seen Mrs. Hemans." Another lady, of stouter fibre, also from across the Atlantic, came stoutly upon her, with a box full of family portraits in her hand, and a mouth full of the oddest protestations of regard possible, and, on taking leave of Mrs. Hemans, remonstrated with her on the melancholy tone of her poetry in general, and entreated to be allowed to introduce a friend of her own, whom she might lean upon "as a perfect walking-stick of friendship," under which happy support, she prophesied that her verses would presently become cheerful—and the gentleman was "long, and lank, and brown," and suitable to the simile. These were mere acquaintances of the hour; but, among her visitors from far-away places, came friends too, and when I remember the evenings I have passed in her little parlor, with herself and Miss Jewsbury, (alas! too early called away!) and Mary Howitt, and Dr. Bowring, and others, I cannot but regret that I have no more specific record of the conversation, which was struck out in this encounter of minds of no common order. It was varied and sparkling, and suggestive beyond most that I have since heard. The two following notes refer to this period—the second to a cruel murder perpetrated upon that fine but most extravagant poem of Shelly's, 'Mary Anne's Dream,' which a gentleman had insisted upon reading aloud, much in "Eccles' vein:"—

"Thank you for your very kind note: I was much better when it arrived, but did not feel the less gratified by all the cordial kindness of its expressions. My complaint is, indeed, most pertinacious, if not hopeless, as I am assured, and indeed convinced, that it is caused by excitements, from which, unless I could win "the wings of a dove and flee away" into a calmer atmosphere, I have no chance of escaping. I have, therefore, only to meet it as cheerily as I may—and there is a buoyant spirit yet unconquered, though often sorely shaken within me.

"Do you know that I have really succeeded in giving some thing of beauty to the suburban court of my dwelling, by the aid of the laburnums and rhododendrons, which I planted myself, and which I want you to see whilst they are so amiably flowering. But how soon the feeling of home throws light and loveliness over the most uninteresting spot. I am beginning to draw that feeling around me here, and consequently to be happier.

"Did you ever see a letter with a symphony? I

call the enclosed one of that class. After many and long wanderings it reached me this morning with that awful Titanic poem, the —; the sight of which really renews all the terrors of 'Charlemagne.' The opening of Mr. —'s letter strikes me as being so very original, that I send it for your edification."

"I fear you were very unwell the other evening, or did you run away so early, to escape the infliction of another 'Dream?' I was quite afraid of looking at you, lest I should have laughed. I had such a levee, yesterday morning, I was as much inclined to run away from all, as from Bishop and Dean, and sofa-table, and Chinese puzzles of old. — and — called upon me—what a butyraceous looking pair they are! Something was said of Montgomery's 'Pelican Island,' and with your comparison of the penguin, and my Welsh recollections full in my head, I had the narrowest escape possible of calling it 'Puffin Island.' How do poets contrive to grow so fat? I suppose it is only translators who can do so, and what the country people call 'nice quiet gentlemen' poets. However, I liked them both, they looked so extremely comfortable."

"\* \* \* I send you the Moravian air, and this is the old Swedish tradition of which I was speaking to you last night, when the public entered and interrupted me. There is a dark lake somewhere among the Swedish mountains—and in the lake there is an island of pines—and on the island an old castle—and there is a spirit harper who lives far down in the lake and when any evil is going to befall the inhabitants of the castle, he rises to the surface, and plays a most mournful ditty on the shadowy heart, and they know that it is a music of warning. I met with it in 'Olaus Magnus,' such a strange wild old book; did you ever read it?"

These last notes are further interesting, as showing what may be well called "the rainbow hue" of the poet's mind, how near to each other dwell its livelier and its deeper feelings. But the world in general is singularly unwilling to admit this double power and I have often thought that a fear of its censure which Mrs. Hemans confined herself—though and remark, narrowed the class of subjects to again it may be said, that she never wrote save when in earnest, and that the lonely and prevailing thoughts of her mind, (I speak of it in a comparative calmness—there were times when they were of a much sadder hue,) were of that lofty, and noble, and chivalresque character, which speaks out in her poetry; something of this will be seen in further selections from her letters, which I shall give.

It was during Mrs. Hemans's residence at Wavertree, that she paid two long visits to Scotland, and a third to the Lakes. Perhaps the time she spent in Edinburgh and its neighborhood, was the most public part of her life—the sensation of curiosity she excited among the circles of "modern Athens," was great—and the attention lavished on her must, some of it, have been hard to bear with a grave face. One lady pursued her to the Castle garden, and introduced herself "as having discovered her to be Mrs. Hemans by a secret sympathy, which assured her she could not be mistaken"—one, herself a writer of no inconsiderable fame, desired to know, "whether a bat might be allowed to appear in the presence of a nightingale." These anecdotes are gathered from eyewitnesses—but a part of her Scotch journey will be best told in one or two of her own letters:—

Chieftwood, July, Tuesday morning.

"Whether I shall return to you all "brighter and happier" as your letter so kindly prophesies, I know not: but I think there is every prospect of my returning, more fitful and wilful than ever; for here I am leading my own free native life of the hills again, and if I could but bring some of my friends, as the old ballad says, 'near, near, near, me,' I should indeed enjoy it—but that strange solitary feeling which I cannot chase away, comes over me too often like a dark sudden shadow, bringing with it an utter indifference to all things around. I lose it most frequently, however, in the excitement of Sir Walter Scott's society, and with him I am now in constant intercourse, taking long walks over moor and woodland, and listening to song and legend of other times, till my mind forgets itself, and is carried wholly back to the days of the Siogan and fiery Cross, and the wild gatherings of Border chivalry. I cannot say enough of his cordial kindness to me; it makes me feel when at Abbotsford, as if the stately rooms of that ancestral looking place, were old familiar scenes to me. Yesterday he made a party to show me 'the pleasant banks of Yarrow,' about ten miles

from hence; I went with him in an open carriage, and the day was lovely, smiling upon us with a real blue sunny sky, and we passed through I know, not how many storied spots, and the spirit of the master mind seemed to call up sudden pictures from every knoll and cairn as we went by, so vivid were his descriptions of the things that had been. The names of these scenes liad to be sure, rather savage sounds; such as 'Sleat Man's Lea,' 'Dead Man's Pool,' &c., but, I do not know whether these strange titles did not throw a deeper interest over the woods and waters, now so brightly peaceful—we passed one meadow on which, Sir Walter's grandfather had been killed in a duel—"Had it been a century earlier," said he, "a bloody feud would have been transmitted to me, as Spaniards bequeath a game of chess to be finished by their children,—and I do think, that had he lived in those earlier days, no man would have more enjoyed what Sir Lucius O'Trigger is pleased to call 'a pretty quarrel.' The whole expression of his benevolent countenance changes, if he has but to speak of the dirk or the claymore: you see the spirit that would 'say amidst the trumpets, ha! ha!' suddenly flashing from his gray eyes, and sometimes, in repeating a verse of war-like minstrelsy, he will spring up as if he caught the sound of a distant gathering cry.

"But I am forgetting beautiful Yarrow, along the banks of which, we walked through the Duke of Buccleugh's grounds, under old, rich, patrician looking trees; and at every turn of our path, the mountain stream seemed to assume a new character, sometimes lying under steep banks, in dark transparence, and sometimes

Crested with lawney foam,  
Like the mane of a cheesnut steed.

And there was Sir Walter behind me, repeating, with a tone of feeling as deep as if then only first awakened.

They sought him east—they sought him west,  
They sought him far with wail and sorrow;  
There was nothing seen but the coming night,  
There was nothing heard but the roar of Yarrow.

It was all like a dream. Do you remember Wordsworth's poem, 'Yarrow visited?' I was ready to exclaim in its opening words, 'And is this Yarrow?' There was nothing to disturb the deep and often solemn loveliness of the scenery: no rose colored spencer, such as persecuted the unhappy Count Forbin amidst the Pyramids—Mr. Hamilton, and Mrs. Lockhart, and the boys who followed us, were our whole party; and the sight of shepherds, —real, and not Arcadian shepherds,—sleeping under their plaids, to shelter from the noon-day, carried me at once into the heart of a pastoral and mountain country. We visited Newark Tower, where, amongst other objects that waken many thoughts, I found the name of Mungo Park, (who was a native of the Yarrow vale,) which he had inscribed himself shortly before leaving his own bright river, never to return. We came back to Abbotsford, where we were to pass the remainder of the day, partly along the Ettrick, and partly through the Tweed: on the way, we were talking of trees—in his love for which, Sir Walter is a perfect Evelyn. I mentioned to him what I once spoke of to you, the different sounds they gave forth to the wind, which he had observed: and he asked me, if I did not think that an union of music with song, varying in measure and expression, might in some degree imitate, or represent, those 'voices of the trees.' He described to me some Highland music of a similar imitative character, called the 'Notes of the Sea Birds'—barbaric notes truly they must be. In the evening, we had a great deal of music; he is particularly fond of national airs, and I played him many, for which, I wish you could have heard how kindly and gracefully he thanked me. But, O! the bright swords! I must not forget to tell you how I sat, like Minna in the 'Pirate,' (though she stood or moved, I believe,) the very 'Queen of Swords.' I have the strangest love for the flash of glittering steel, and Sir Walter brought out, I know not how many gallant blades to show me; one which had fought at Kilbernie, and one which had belonged to the young Prince Henry, James the First's son, and one which looked of as noble race and temper as that with which Cœur de Lion severed the block of steel in Saladin's tent. What a number of things I have to tell you. I feel sure, that my greatest pleasure from all these objects of interest, will arise from talking them over with you when I return. I hope you have received my letter with an account of the Rhymer's Glen, and the

little drawing of Chiefswood, for which I now send you a pendant in one of Abbotsford, which is at least recommended by its fidelity."

#### SUMMARY.

**JOHN RANDOLPH OF ROANOKE.**—"E'en in his ashes live his wonted fires," for even now that he has long ceased to be of the number of the living, the peculiarities of his temper, keep alive the interest about him. The Virginia Court, after being occupied some time about the validity of certain of his wills, have decided by a bare majority in favor of that of 1832. An appeal is to be taken. Meanwhile, the Richmond Enquirer publishes that will, which we subjoin. We agree with the Enquirer that it is "a remarkable document," and marked with "originality"—but what does the Enquirer mean in saying it is "stamped with the genius of that extraordinary man?"

[From the Richmond Enquirer.]

**GENERAL COURT.**—*John Randolph's Will.*—On Friday, the argument on the Will was continued.—Mr. John M. Patton appeared as counsel for the committee of Henry St. George Randolph, the nephew of John Randolph. Mr. P.'s object was to set aside all the Wills which had been offered for probat. Gen. Walter Jones closed the argument on Friday, in opposition to the Will of January 1, 1832. On Saturday, Mr. Chapman Johnson concluded the argument in support of the Will.

Yesterday, the Court proceeded to pronounce their opinion on the validity of the Will of 1832—but without assigning their reasons.

The following Judges, decided in favor of the Will, viz: Judges Saunders, Parker, Field, May, Duncan and Estill. The following Judges decided against the Will, viz: Judges Smith, Lomax, Scott, Thompson and Clopton.

The Will has, therefore, been admitted to probat by a majority of one. But an appeal has been taken to the Court of Appeals.

**IN THE NAME OF GOD, AMEN.**—I, John Randolph, of Roanoke, in the county of Charlotte, and Commonwealth of Virginia, do ordain and appoint this my last Will and Testament, hereby revoking all other Wills and Testaments and codicils whatsoever, in manner and form following; that is to say: On the first day of January, one thousand eight hundred and thirty-two, to which I have set my hand and affixed my seal, binding my heirs and assigns forever.

I give and bequeath all my estate, real and personal, in possession or action, reversion or remainder, to John C. Bryan, only son of John Randolph Bryan and Elizabeth Coalter his wife, daughter of my dear sister Fanny, for and during the life of the said John C. Bryan, with remainder to his eldest son, in fee simple, to him and his heirs forever: and in defect of such issue, then to the son of Henry St. George Tucker, called John Randolph, after me, for and during his natural life, with remainder to his eldest son; and, in defect of any such issue, then to Tudor Tucker, brother of the aforesaid Randolph Tucker, for and during his natural life, with remainder to his eldest son.

And I do hereby appoint my friends, Wm. Leigh of Halifax, and my brother, Henry St. George Tucker, President of the Court of Appeals, Executors of this my last will and testament, requiring them to sell all the slaves and other personal or perishable property, and vest the proceeds in Bank stock of the Bank of the United States, and in default of there being no such Bank, (which may God grant, for the safety of our liberties,) in the English three per cent. Consols, and in case of there being no such stocks (which also may God also grant for the salvation of Old England,) then in the United States three per cent. stock, or in default of such stock, in mortgages on land in England.

From the sale of my perishable property I except my library, books, maps, charts, and engravings included, my pictures, plate, household linen, and the furniture of my bed chamber in the old house, and all the furniture in the new house, wines, together with such other articles as my said Executors may deem proper to keep for the benefit of the heir. And my will and desire is, that my said Executors may select from among my slaves a number, not exceeding one hundred, for the use of the heir, the remainder to be sold. I also desire that my Bushy Forest Tract of land may be sold

and made chargeable with such debts and legacies as hereafter I may see fit to give, when I shall have more leisure to make my Will—this being made in consequence of having cancelled a former Will this night, in presence of William Leigh aforesaid, the sole Executor under that Will, and joint Executor under this Will, which I make to guard against the possibility of dying intestate.

I have in the Bank of Virginia upwards of 20,000 dollars, of which sum I desire payment to be made for the land purchased by me the day before yesterday, of Elisha E. Hundley; and I bequeath the remainder to be equally divided between my said Executors, Wm. Leigh and H. S. C. Tucker, Esquires; and I further charge my Bushy Forest estate with a further legacy to John Randolph Leigh, youngest son of Wm. Leigh aforesaid, of five thousand dollars.

And it is my will and desire, that no inventory be taken of my estate, except of slaves and horses, and that no security be given by, or required by my said Executors, having full faith in their honor, neither shall they be held to account to any Court or persons whatsoever, for their discharge of this trust so confided by me in them.

To Dr. John Brockenbrough I leave all my French plate, now in Richmond at J. P. Taylor's. Also my chariot and harness, and the horses called John Bull and Jonathan, alias John W.

To John Wickham, Esquire, my best of friends without making any professions of friendship for me, and the best and wisest man I ever knew, except Mr. Macon, I bequeath my mare Flora, and my stallion Gascoigne, together with two old-fashioned, double-handled silver cups and two tankards, unengraved—the cups are here and the tankards or cans in Richmond, and I desire that he will have his arms engraved upon them, and at the bottom these words, "From J. R. of Roanoke to John Wickham, Esquire, a token of the respect and gratitude which he never ceased to feel for his unparalleled kindness, courtesy and services."

To Nathaniel Macon I give and bequeath my oldest high silver candlesticks, my silver punch ladle with whalebone handle, a pair of silver cans with handles and my crest engraved thereon, my hard metal dishes that have my crest of J. R. in old English letters engraved thereon, also the plates with the same engraving, the choice of four of my best young mares and geldings, and the gold watch by Roskell, that was Tudor's, with the gold chain; and may every blessing attend him, the best and purest and wisest man I ever knew. To my brother Henry Tucker, my gold watch by Barwise.—The chronometer by Arnold, and knives and forks, &c. from Rodgers, to go to the heir. To William Leigh, all duplicates of my books, and my brood mares Last Chance and Amy. To H. Tucker, Young Whalebone and Young Never Tire, also Topaz and Janus, and Camilla, and Marcella.

JOHN RANDOLPH, of Roanoke.

**PROGRESS OF AMERICAN MANUFACTURES.**—We have just seen the exhibition card of American buttons, manufactured by Ives, Scott & Co., Waterbury Ct.—of whom Clark & Walton are the agents—and certainly, no where, we apprehend, can more finished specimens of the different varieties of buttons be seen, than this card exhibits.—So successful, indeed, has this manufacture become, that it now, as we understand, defies competition from abroad.

**NORFOLK, July 19.**—*Naval.*—It is rumored that Com. Morris will be ordered to the North Carolina 74, at present undergoing repairs at the Navy Yard, Gosport. That Com. Elliott, will be detached from the Constitution, and take the place of Com. Morris in the Navy Board. Capt. Shubrick, will be ordered to the Constitution. Purser Etting has also been detached from the Constitution, and Purser John N. Hambleton ordered to that ship.—[Beacon.]

**NAVAL.**—The United States ship Erie, Captain Percival, sailed from Buenos Ayres, June 1, for Mont Video and Rio Janeiro.

The Commencement of Union College (Schenectady), took place on the 23d instant. The degree of A. B. was conferred on eighty-eight members of the graduating class.

The honorary degree of A. B. was conferred on Wm. Belden, Jr. of Brooklyn, N. Y.

The honorary degree of A. M. was conferred on

Amos W. Brown, Adam Crounce, Lyman Cobb, and Caleb Tichenda. The same degree was conferred on 20 of the Alumni of the College.

The degree of D. D. was conferred on the Rev. John Breckenridge; that of L. L. D. on Roger B. Taney, of Washington City, and Abraham Van Vechten, of Albany.

We learn by the ship Hope, which arrived at New Bedford on Friday last, from Talcahuana, that the people at that place are busily employed in rebuilding the town, which had been totally destroyed by an earthquake. The editor of the N. Bedford Mercury says—"It is an old saying with the Spaniards in that country, that earthquakes do not visit them but once in a century; therefore they feel full confidence that they shall not be disturbed again in the present generation, and the rest they leave to posterity. The style of building, streets, &c. is to be much improved.

**UNITED STATES AND RUSSIA.**—The Globe of Wednesday contains the following article:—"It will be recollected that a Convention was concluded between the United States and Russia in April 1824, regulating various matters connected with the commerce and navigation of the two nations on the northwest coast of America. By the 4th article it was stipulated that the ships of both nations might, during a term of ten years, frequent, without hindrance, the interior seas, gulfs, harbors, and creeks of each nation on that coast, for the purpose of fishing and trading with the natives of the country. The ten years expired in April, 1834; and we understand that formal notice has been given by the Governor of the Russian Colonies, to the masters of the American ships then trading there, that they could no longer claim, under the Convention, the right of landing at all the landing places, without distinction, belonging to Russia on that coast. Those interested in the trade will not fail to observe that, under the 2d article of the Convention, it is necessary for all American vessels, resorting to any point on that coast, where there is a Russian establishment, to obtain the permission of the Governor or Commander."

**LINE OF PACKETS BETWEEN CHARLESTON, S. C., AND LIVERPOOL.**—We learn from the Charleston Courier, of 20th inst., that active efforts are making to form a joint stock company, with a capital of \$150,000, for procuring four packet ships, to sail at stated intervals, between that city and Liverpool. The shares are \$500 each. Mr. Wm. Scarborough, of Charleston, had undertaken to furnish one ship—subscriptions sufficient for another had already been received, so that one half of the stock may be considered as taken.

**A STRANGE FISH.**—A sea monster has been caught somewhere in the neighborhood of Norfolk, which is thus described by the Norfolk Beacon:

"Its general outline is that of a turtle, the fins or flappers being much longer. The whole fish is covered with a shining black cuticle or outer skin, (easily removed,) with the exception of the top of the head and the spinous processes of the back, which are white, with irregular outlines, as if it had been rubbed in three places. Immediately under the skin is a bony covering, extending over the back and down the sides, ridged with seven or nine bony prominences or spines, running nearly parallel with the back bone. The head is that of a turtle, with the upper lip or bill notched, so as to form two prominent pointed teeth or tusks. The throat and inner part of the mouth is fretted with spikes about two lines thick at the base, an inch long, of a horny substance, hanging loosely, but looking towards the throat, so as to permit a ready entrance, and completely preventing regurgitation, or egress. It measures eight feet in length, and nine feet from tip to tip across the fins.

It is said that as many as two thousand persons are now suffering at Baltimore, from the effects of a poisoned sugar. The disease baffles the skill of the doctors.

**TEN TO ONE.**—Strict attention to office hours is a duty incumbent on every public officer. We heard of a case once of an American Consul in a foreign country, who was not remarkable for his attention to duty. A gentleman calling upon him

one day, found his office shut, and a label sticking upon the door with these words: "In from ten to one." Having called again several times within those hours, without finding him, he wrote at the bottom of the label, "Ten to one he's not in."—[Philadelphia Gazette.]

**THE JERSEY CITY GAZETTE.**—We do not, in all our exchange list, receive a neater, better printed, or more carefully got up paper, than this semi-weekly from over the river. It is owned and edited by *Robt. U. Lang*. It is creditable, and we hope profitable, to him, and may too be looked upon as "a sign" of the growth and improvement of *Jersey City*, where it is printed.

**CHICAGO, July 18.**—**THE LAND SALES.**—The amount of money received at the Land Office in this town for lands sold from 28th May till the close of the land sale, is a little over \$386,500, of which about \$353,500 were for lands sold at auction, and the balance under the preemption law. The exact amount cannot, as yet, be ascertained.

[COMMUNICATED FOR THE N. Y. AMERICAN]  
In the year 1801, Mr. and Mrs. B. visited the Highlands of Scotland. The previous year, the crops were bad, and of course they expected to hear of great suffering among the poor. Mrs. B. on being asked if this had not been the case, replied, "I have never known less distress than during the dear year, as it was called. All the distilleries were stopped by order of Government; of course the grain usually employed in them, was in the market for food. This put the price of liquor beyond the reach of the poor, and being sober they worked more, and were more healthy. No doubt the rich helped them but little, if any more, than in former years." X.

**SHOEMAKING AT LYNN.**—It is estimated that not less than two million pairs of shoes were made at this place during the past year—giving employment to nearly four thousand persons.

**GOLD LEAVES.**—About two millions of gold leaves are manufactured in London per week. The intrinsic value of each is about one half penny, or nearly a cent of our money.

**LARGE FREIGHT.**—The Steamer *Wm. Gibbons* which arrived on Wednesday from Charleston, brought about 200 passengers. Any packet to or from Europe would be thankful to earn as large a freight. The steamboat arrangement to Charleston is one of great public utility, and we are happy to see it so abundantly rewarded.—[Journal of Com.]

**SINGULAR.**—The Montreal Herald states that a laboring man named Hawkins, died in that city on the evening of Sunday, the 19th instant, from the effects of a sting on the cheek, from some venomous insect, on the previous Thursday. Before medical advice was resorted to, breathing was obstructed, and the swelling had extended over the greater portion of the body. He expired in a most dreadful state of agony, and has left a wife and six young children. What species of insect he was stung by, the Herald says, we could not ascertain, but he described it as having been very small.

#### EUROPEAN INTELLIGENCE.

**FOREIGN NEWS BY THE ROSCOR.**—We gave yesterday a brief abstract of the chief items of intelligence by this ship. A more deliberate perusal of our papers—since received—enables us to add some details.

The Morning Post of the 23d, discredited the rumor that *Zumalacarraguy* had been wounded, and the victory of *Iriarte*. The Courier seems to believe both. We, therefore, publish the accounts from the Paris papers, together with the notice, that the Carlists had actually undertaken the siege of *Bilboa*:

**PARIS, June 20.**—The *Journal de Paris* of last night contained the following intelligence:—  
"A telegraphic despatch of this morning announces that on the 16th inst., *Zumalacarraguy* was grievously wounded in his right thigh, and resigned his command to *Erazo*. He has been conveyed to *Durango*.

On the 18th the siege of *Bilboa* was still going

on. Intelligence is expected from *Valdez*, who is advancing to the relief of the town."

This wound of *Zumalacarraguy* may be reckoned a victory for the *Christinos*, for almost all the defeats they have experienced, have been due to that brave and talented chief. *Erazo*, though a brave and clever officer, is vastly inferior to *Zumalacarraguy*.

Thus all the reports respecting the taking of *Bilboa* have turned out false; and it is very probable that it will not fall into the hands of the Carlists now that *Valdez* is hastening to its relief, and that *Zumalacarraguy* is no longer with his men to guide them to victory.

The Urban guard and the garrison of *Bilboa* are resolved not to surrender; they have sworn to bury themselves beneath its ruins rather than deliver up the town to their enemies. Heavy artillery has been sent them from *St. Sebastian*, and cannons have been posted in the streets to oppose the Carlists, should they attempt to force an entrance. This resolution will doubtless meet with success.

The latest intelligence (the Ministerial Bulletin excepted) which has been received from *Bilboa*, is of the 14th: at that time the town was blockaded by *Zumalacarraguy*, and several shells had been thrown into it. This news was brought to *St. Sebastian* by a steamer.

There is every reason to believe that the Queen's troops have obtained a decisive victory over the Carlists in the vicinity of *Vittoria*. There are, however, two versions of the action. I shall send you both, commencing with the one which I consider the most entitled to credit, and which is to the following effect:—

"On the 11th instant a serious encounter took place within two leagues of *Vittoria*. *Valdez* feigned to be retreating on *Vittoria*, and sent the major part of the 9,000 men he commanded to that town. The Carlists, whose forces consisted of twelve battalions, fell with great impetuosity on the *Christino* General's cavalry and infantry.—*Valdez*, by a manoeuvre, which he had concocted previously, then made his troops come up with such rapidity that the attacking Carlists were instantly broken, and the field of battle covered with their slain; 400 Carlists were besides made prisoners by the Queen's troops."

This account was brought by the steamer I have just alluded to.

The other account is contained in a letter addressed yesterday evening to the *Messenger*, by the Spanish General *Mendez Vigo*. It gives no date, and asserts that *Zumalacarraguy* commanded the Carlists defeated on this occasion, and that from 3,000 to 4,000 prisoners were made by the *Christinos*, whose forces consisted but of four regiments of infantry and 600 horse, under the command of General *Iriarte*, who, it must be owned, is a gallant officer. The following is the extract from *Mendez Vigo's* letter:

"I have just received a letter from *Bayonne* of the 13th, stating that General *Iriarte* has fought a glorious action with *Zumalacarraguy* in person, within four leagues of *Vittoria*. This General, who was accompanying *Expartero* in his retreat from *Bilboa*, on battle being offered by the insurgents, put himself at the head of four regiments of infantry and 600 cavalry, and completely defeated the Carlist chief, from whom he took from 3,000 to 4,000 men, and all his artillery, which consisted of seven field pieces."

On the other hand, the garrison of *Bergara* has joined the Carlists. This has also been the case with 150 men of the garrison of *Villafraanca*; the remaining 230 have been escorted to *Bilboa* by the Carlists.

The garrison of *Eybar* is said to have surrendered as prisoners of war, and it is stated that the Carlists found in that town 4000 muskets, 7 cannon, &c., besides a good supply of ammunition, military stores, and provisions.

The *Navarre* Junta entered *Elisondo* on the 13th. There are 5 Carlist battalions in the neighborhood of that town.

The *Renovateur* of yesterday reported that the celebrated *El Pastor*, the Commandant General of *Guipuscoa*, has taken refuge in France. This must certainly be an error. The patriotism of *El Pastor* is well known. The brave General has several relations in the vicinity of *Bayonne*, and a visit to them has probably been converted by his enemies into a desertion of his duty. S.

[From the Messenger.]

PARIS, June 20.—The *Sentinelle*, of the 16th,

confirms the advantage gained by *Iriarte*. It says: "We learned yesterday, and we are assured, that General *Iriarte*, who was at *Vittoria*, seeing some Carlist battalions, with seven cannon, approach the town, resolutely sallied out to meet them, with 400 cavalry and some infantry. Having killed many of their men, and captured the seven cannon, *Iriarte* returned to *Vittoria*."

The first part of the following letter from our correspondent, may throw some light on the telegraphic despatch dated the 19th, and announcing the wounding of *Zumalacarraguy* on the 16th:

"**BAYONNE, June 16.**—The Carlists are besieging *Bilboa*, and many families who have quitted that city arrive here every moment. The most recent accounts that we have received are, that the firing on the town commenced the day before yesterday, at nine in the morning, with eight cannon and one mortar.

"The firing was pretty brisk till two o'clock in the afternoon; at that moment it suddenly ceased. We do not know where it was re-opened afterwards, or whether the arrival of *Valdez*, who is known to have marched in that direction, had rendered a battle or a retreat necessary.

We must soon learn the truth. *Valdez* was at *Vittoria* with 22,000 men, including the reinforcements brought by *Espartero*, and being only nine leagues from *Bilboa* would be inexcusable if he suffered a town of such importance to be attacked without making a vigorous attempt to succor it.

*Bilboa* has 5,000 men within its walls, and must have received some reinforcements from *St. Sebastian* and *Santander*, which set out the day before yesterday.

Colonel *St. Yon*, the officer commissioned by the French Minister of War to watch the progress of the insurrection in the North of Spain, had returned to Paris, and made his official report of what he witnessed, including his opinion of what force would be necessary to put an end to the conflict. He says that a force of at least 120,000 men, and a four years' occupation of the territory, would be required to crush the rebels, and even then there would be no security against future insurrections, after the withdrawal of the troops: but he adds, that there is no danger of the overthrow of the existing Government of Spain, because as soon as the Carlists cross the *Ebro*, they are in "an enemies country."

The border war between Ohio and Michigan, figures largely in the London papers, as though it might lead to something.

The present *Earl of Devon*, (the successor of Lord Courtenay) was a deputy clerk of Parliament when the title fell to him.

The death of *Cobbett* is variously commented on by the London press, the language of eulogy being chiefly used in regard to him, by the *Tory* papers!

His death seems to have been occasioned by inflammation of the throat, and consequent debility.

We have among our miscellaneous extracts inserted a notice of this extraordinary man from the *Morning Chronicle*.

**COTTON FROM ALGIERS.**—Some specimens of the cotton grown in *Algiers*, which have recently been sent to Paris, have excited considerable surprise. The cotton is superior to that imported from *New Orleans*. It is finer and stronger, and will bear comparison with either the cotton from *Bourbon* or *Cayenne*.—[Le Voleur.]

**FROM FRANCE.**—By the *Champlain*, *Havre* papers of 17th ult., with Paris accounts of the 16th, are received. We have examined the *Havre Journal* of the 16th and 17th, politely put at our disposition by the *Daily Advertiser*, but find nothing of interest.

The *Moniteur* contains officially the law for the payment of the American claims, agreeably to the votes of the two Chambers. A sketch of the debate in the Peers on the day the bill passed, may be found below,

**CHAMBER OF PEERS—Session of June 12.**  
 Presidency of the Count Portalis (Vice President.) Messrs. Duperré, Maison, de Broglie and Duchatel are on the Minister's Bench.

The order of the day calls for the discussion on the report of a law for carrying into effect the American treaty.

M. de Barante applies himself to justify the report of the Committee, and to reply to the objections made yesterday by the adversaries of the law. He closes with persisting in the conclusions of the committee who proposed the adoption of the law.

The Chamber proceeded to take up the different articles of the law.

Article 1, is put to the vote.

M. Dubouché complains that the power of the Chambers has been entirely misunderstood, and requires that the interest should not accrue before the day on which the Chambers may have adopted the law.

M. de Broglie in a few words replies to M. Dubouché. No further debate ensued, and the article is adopted.

M. de Barante made some observations on Art. 2. He requires that Government shall not lose sight of the interests of those who have ceded land in Louisiana, and thinks that 1,500,000 francs reserved will not be sufficient to meet the claims which will arise. M. de Broglie replies, that the Government will continue to support these claims as it has always done.

Articles 2 and 3 are adopted.

The Chamber proceeded to vote on the whole Bill. The following is the result. Votes 147—white balls 135, black balls 22. The law is adopted by the Chamber.

The Chamber of Peers on the 16th was occupied all day with trying the prisoners of April.

Rumors of the success of the Carlists, in different parts of Spain were circulating, and had affected the French Funds a little. *Bilboa* was said to have fallen into their hands—and at *Burgos*, the republic was said to be proclaimed. Nothing authentic, however, is given.

The dates from Madrid are of the 11th. By a decree of the 10th, the Queen accepted the resignation of *Martinez de la Rosa*, and named Count *Torreano* President of the Council of Ministers for foreign affairs, *ad interim*.

The *Monitor* has the following:—"It being the intention of the King to authorize all such Frenchmen as wish to enter into the service of the Queen of Spain, to do so without losing the quality of their citizenship to France, all demands for such authorization must be addressed to the Ministers of Justice, conformable to Art. 21 of the Civil Code."

[Gleanings from European Papers.]

A Lyons paper of the 13th states, that at *Menandria*, in Piedmont, on the 5th, some eighty persons of the Jewish persuasion being assembled in the third story of a building, to celebrate a wedding, at the moment of beginning a dance, the floor gave way, carrying with it all the company, and breaking through the 2d and 1st floors, buried them beneath the ruins. Thirty-six of the number were dug out dead, and twelve others died the next day of their wounds. Among the dead was the Colonel of a regiment in garrison there, and the Jewish Rabbi.

Lord *COURTENAY*—who passed some years in this country, and has since lived in France, recently died there. He had become Earl of *Drvon* during his forced exile.

His English property goes to a nephew in England, but his beautiful estate of *Dravell*, near Paris—well and happily do we remember it, in other days, when owned by an American—with all its furniture, he left, as we learn by the Paris papers, to a servant. This legacy is estimated at two millions of francs. The brother of the legatee keeps an English eating house in Paris.

It is said that a marriage between the Duke of Orleans, and a princess of Wittenberg is seriously agitated, and that the Emperor Nicholas, whose

influence at the Court of Stutgard is paramount, far from opposing, favors such an alliance.

**CHEAPNESS OF BOOKS IN FRANCE.**—Capt. Ross's two guinea and a half volume, of his arctic residence is re-printed in Paris for five francs, about one twelfth.

*Mr. Glover*, an English Artist, has gone to *Van Deimen's Land*, for the purpose of taking views of its peculiar scenery—and sending them home for exhibition.

Lord Gosford, the newly appointed Governor of the Canadas, has been created an English Peer by the title of *Baron Worthingham*, of Beccles, in the county of Suffolk.

**BUENOS AYRES.**—By the *Braganza*, dates from Buenos Ayres to the 9th of June have been received.

Captain *Pierre Espiaux*, of the French frigate *Thisbe*, died at Buenos Ayres on the 17th of May, and was buried with military honors on the 19th. Among the attendants at his funeral were Mr. *Dorr*, the United States Consul, and Capt. *Percival* and the officers of the United States sloop of war *Erie*.

The British sloop of war *Acteon*, Lord *Edward Russell*, commander, arrived at Buenos Ayres on the 31st of May, having sailed from Plymouth on the 22d March.

Some interest appears to have been created by the detention of a French brig—the *Hermione*—on suspicion of having smuggled goods on board. A long correspondence ensued between the Government and the French Consul, the result of which was, that the brig was allowed to sail, merely, however, as an indulgence—the laws having been much relaxed heretofore—but notice is given that henceforth they will be most rigidly enforced.

A splendid ball was given by Mr. *Hamilton*, Minister Plenipotentiary of his Britannic Majesty, on the 28th of May, in honor of the King's birthday. Captain *Percival*, and Lieutenants *Pope*, and *Eagle*, of the *Erie*, were among the guests.

The *America*, at Boston, from Calcutta, whence she sailed March 19, reports that Lord *Wm. Bentick*, Governor General of India, left Calcutta two days previous in H. B. M. ship *Curacon*, for England. Sir *Charles Metcalf*, Governor General of Arga, acts as Governor General of India, until a new appointment.

#### Love in the Dew.

A maiden went forth at the twilight hour,  
 To meet her true love in a dewy bower.  
 Where the rose and sweet briar and jessamine grew,  
 And the humming bird kissed from their flowers the dew  
 She was bright as that bird of the glittering wing.  
 And pure as the dew-drop, and gay as the spring.  
 And there in the shade,  
 The youth wooed the maid;  
 But the moon rose high,  
 In the cloudless sky,  
 'Ere she gave her consent and received the ring.  
 And then she flew,  
 From love and from dew,  
 To dream of them both the long night through  
 The night has fled, and the dew is gone,  
 The maiden sits in her cottage alone:  
 She is thinking of love and moonlight hours,  
 Of dewy kisses and jessamine bowers;  
 And she wonders if rings and vows are true;  
 Or as cold as night, and as fleeting as dew,  
 But her hope is bright,  
 And her heart is light,  
 And still she sings  
 Of bridal rings,  
 Of rose-buds and vows the long night through.  
 And all her theme  
 Is that bright dream,  
 That came o'er her heart by the moon's pale beam.  
 The maiden is clad in her bridal dress,  
 The priest is there to unite and bless;  
 And beside her the bridegroom has taken his stand,  
 To taste of her lip and to touch her hand,  
 And to wed in the face of the world the maid  
 Whom he wooed at night in the jessamine shade.  
 No eye more bright,  
 No heart more light,

Than her's, the bride,  
 Who smiles in her pride,  
 For the ring is here, and the vow is paid.  
 But maidens beware  
 Of the dew and night air,  
 Not always are truth and gold rings found there.

[FOR THE NEW-YORK AMERICAN.]

**Musings.**—By *Flaccus*, in the Country.

ABSENCE—A SONG.

The heart no deeper gloom can know,  
 Than absence's tomb-like solitude—  
 I better bore thine anger's glow  
 Than the dull peace which has ensued—  
 Give back mine eyes, thy form again!  
 Give but mine ears, thy quick'ning voice  
 And though thy glances flash disdain,  
 And words speak daggers, I'll rejoice!—  
 For oh! reproach I could forgive,  
 How'er it jarr'd my brain to hear;  
 And e'en thy fury's gaze outlive,  
 To know but this, that thou wert near—  
 A charm, thy words and looks contain,  
 That numbs their power to harm, or kill;  
 Like painted rage, or charmed pain,  
 'Tis beauty, and 'tis music still—  
 For, shot through eyelids plumed like those,  
 Thy glance must of itself softness share;  
 And through those lips, the curse that flows,  
 Comes sweeten'd from the honey there—  
 I must return!—though doubly curst—  
 Though all thy lightnings scathe my brain,  
 I care not—I have known the worst—  
 For absence owns no master-pain.—

No. 6.

W.

[From the *Cazenovia Rep. Monitor*.]

**ORIGINAL POETRY.**—The following lines are the production of a lad of 13 years, a student in one of our literary institutions. They were suggested by viewing an engraved representation of *Fingal's Cave*, in the possession of his room mate. The reader will better understand the argument of the poem, and better appreciate the talents of the juve; nile author, by being informed that *STAFFA* is a small island of Scotland, one of the Hebrides; and is accounted one of the greatest natural curiosities in Europe, if not in the world; the whole south-west end being supported by ranges of basaltic pillars, mostly above 50 feet high, and four feet in thickness. The magnificent cavern, called *Fin-macoul*, or *FINGAL'S CAVE*, is on this island, and extends 250 feet in length. Its entrance is a natural arch, 53 feet wide and 116 high, from which the cavern is lighted, so that its farthest extremity may be seen. It is supported on each side by ranges of columns, and roofed by the fragments of others that have been broken off in forming it. The bottom of the Cave is filled by the sea, reaching to the extremity, and in very calm weather a boat may sail into it.

**Staffa.**

I've gazed on Nature in the sleepy lake,  
 The green-clothed field, and wildly tangled brake;  
 I've heard her whisper in the flowering trees,  
 Sing in the brook and murmur in the breeze,  
 Until her quiet music, to my heart  
 Would love and peace and happiness impart,  
 And every fretful feeling die away,  
 Like lover's frowns before his loved one's lay.  
 And then I've turn'd, on wilder scenes to brood,  
 And court thee, Nature, in thy sterner mood;  
 Have seen the cloud-envelop'd mountain ride,  
 The tranquil forest sleeping on its side,  
 But not those scenes such pleasing fear impart,  
 As *STAFFA'S* rugged isle, where Nature scorns at Art!  
 Here, on the bosom of the dark blue sea,  
 That longs to trespass on earth's boundary,  
 'Neath lowering skies, amid whose twilight grey,  
 The joyous sunbeams seem afraid to play—  
 Serenely calm, in solitary pride,  
 A glorious pile reposes on the tide:  
 From ocean's depths the giant columns rise,  
 And lift the self-born structure to the skies.  
 Firm on its rocky base each pillar stands,  
 No chisel'd shaft, no work of mortal hands.  
 Ere man had ceased in savage woods to dwell,  
 (Roots for his food, his drink the crystal well,) Ere yet he knew the joys of social life,  
 And scarcely sought his fellow but in strife,  
 Ere cities grew, or Parian marble shone,  
 Those columns stood, and stand while they are gone!  
 Yet many a broken pillar strewed around,  
 And many a vista level'd to the ground,  
 Proclaim, that not e'en Nature's works are free,  
 All conquering Time, from thy same mastery!  
 Then, mortal, blush, to own the selfish grief  
 Which prompts a murmur if thy days be brief:  
 When Nature's brightest glories disappear,  
 Shall thy mortality demand a tear?  
 Mark where the portal, yawning o'er the wave,  
 Reveals to view the beauties of the Cave:  
 Majestic columns rise on either side  
 The arched canopy above the tide,  
 Which, mildly glittering with a sparry light,  
 Shines like the appangled firmament of night.  
 'Tis Nature's palace. Scorning to abide  
 In temples less in reverence reared than pride—  
 The surge's roar more grateful to her ear,  
 And tempest hymns, than hollow voice of prayer—

She fled, disdainful of a Doric fan,  
And built her chapel on the Atlantic main!  
Still as we gaze, a feeling more intense  
Grows with each look, and steals on every sense;  
The frowning arch above, the sea below,  
The time-cemented pillars' arched row,  
The ocean wrestling with the pile in vain,  
That hurls its breakers back in calm disdain,  
Blend in a scene so solemn, yet so fair,  
That man seems almost an intruder there!  
Each hollow blast that slowly dies away,  
Sounds like some spirit's melancholy lay;  
And as the harmonious cave sends forth its song,  
You scarce would start to see an airy throng;  
Of mermaids flitting o'er the unruddied wave,  
And breathing low, soft dirges through the cave:  
There is a stillness—not but of the grave—  
A breathless life within that wondrous cave—  
A deep contentment, a mute harmony,  
A holy presence that we cannot see,  
But yet can feel—for Ocean murmurs on,  
As if in prayer, his deep-toned orison;  
And winds without, that rage in lawless din,  
Are hush'd to music as they enter in!

Oh! let the skeptic on whose doubting eyes  
In vain the beauties of creation rise—  
Who, while he views the loveliness of earth,  
Can yet disown the power that gave it birth,  
Here let him gaze, and say 'twas chance alone  
That rear'd the pile and nicely carved the stone—  
That lent each shaft such noble symmetry—  
Alas! it mocks his poor philosophy,  
Tells him a truth he little dream'd before,  
Man was not made to question, but adore.

**CIRCULAR.** To ENGINEERS and Superintendents of Railroads and Canals.—I am preparing to issue a new edition of my RAILROAD AND CANAL MAP; and being desirous to correct the errors of the first edition, I take the liberty to request the ENGINEER, or SUPERINTENDENT, of every Railroad and Canal in the UNITED STATES, to furnish me at his earliest convenience with a full and precise account of the condition of the railroad under his direction or charge. He is requested to state the length of the road, the number of miles completed, the elevation it surmounts, the radius of its curves, the style of its construction, its average cost per mile, the number, if any, of inclined planes, with stationary engines—in short, every thing which may be of interest to engineers, or others who may be connected with the subject of Railroads and Canals.

To such as comply with the above request, and furnish the desired information previous to the first of August next, a copy of the new edition of the Railroad and Canal Map, will be sent, by mail or otherwise, as may be directed, as soon as completed.

D. K. MINOR.

New-York, June 27, 1835.

#### RAILROAD JOURNAL AND ADVOCATE OF INTERNAL IMPROVEMENTS.

This work is published once a week, in quarto form of eight pages, devoted mainly to the subject of internal improvements, in all its various modes and forms. Three volumes were completed in December, 1834, and the 4th volume is now in progress.

Terms, \$3 a year, in advance. Previous volumes same price; full set of four volumes, \$12.

#### RAILROAD AND CANAL MAP.

Or a Map of the United States, 24 by 40 inches, on which is delineated all the Railroads and Canals in use, or in course of construction, and most of those in contemplation; together with a concise description of, or reference to, each, and containing over 70 pages of letter press. The map is on bank note paper, and put up in pocket form, with morocco cover, or in paper cover, and may be sent by mail to any part of the country Price \$3

#### MECHANICS' MAGAZINE, AND REGISTER OF INVENTIONS AND IMPROVEMENTS.

This work has nearly completed five volumes. It is published monthly, in numbers of 64 pages each, in large octavo form, and forms two good sized volumes a year, of 384 pages each.

This work is STEREOTYPED from the first number, and therefore any number of copies may be obtained from commencement, if desired. It has many able correspondents, who furnish original communications, in addition to its selections from the best European periodicals of the day, with numerous engravings and illustrations of the subjects on which it treats. The Mechanics' Magazine may be considered as one of the permanent periodicals of the country. Price, \$3 per annum, in advance. Previous volumes \$1.50 each.

#### THE APPRENTICE'S COMPANION.

A monthly publication, in large octavo form, of sixteen pages each number—designed to persuade APPRENTICES, and others, to habits of INDUSTRY, TEMPERANCE, and FRUGALITY—It is published at the office of the MECHANICS' MAGAZINE, No. 35 Wall street, New-York, for FIFTY CENTS a year—for 12 numbers—by D. K. MINOR.

\* All letters must be postage paid. Eleven num-

bers sent to one address for \$5,—and TWENTY THREE for \$10. D. K. M.

#### NEW-YORK FARMER AND AMERICAN GARDENER'S MAGAZINE.

This work is devoted mainly to AGRICULTURE and HORTICULTURE; it, however, treats upon various other subjects more or less connected with them. It is now in its 8th volume, or 3d volume, new series, and is designed to be made equal to any work of the kind in this or any other country. No reasonable expense will be spared, either to secure the best writers the country affords, or to furnish engravings and illustrations. It is published monthly in large octavo, 32 pages per month, at \$3 per annum, and when paid in advance eight additional pages per month are given. Vols. 6 and 7, or 1 and 2, new series, \$3 per volume.

These works may all, or either of them, be had of S. Blydenburgh, 96 North Pearl street; Albany; D. Hale, 124 Washington street, Boston; Fessenden, Philadelphia; or of the Proprietor and Publisher,

D. K. MINOR,

35 Wall street, New-York.

#### PARTNER WANTED.

Wanted, a partner in an extensive Printing Establishment. No one need apply who is not a thoroughbred printer, competent to superintend and direct an office in which upwards of 30 persons are employed, and able to furnish \$3000 cash capital. The best of references will be given and required. Letters, with real name, may be addressed to P. P. P., Post Office, New-York, postage paid, and they will be promptly attended to. May-17

#### TO TUNNEL MINERS, DRILLERS, &c.

Wanted, immediately, 40 Tunnel Miners, (Cornish Miners will be preferred,) 80 Drillers, 50 Laborers, and two experienced Mine Blacksmiths, on the New York and Harlem Railroad, about five miles from the City. Liberal wages will be given, and cash payments made every fortnight. Apply at Mr. FOWLER'S, St. John's Hall, Frankfort street, New-York.

JOHN BUTTER, Contractor.  
The Albany Argus, Philadelphia U. S. Gazette and Pennsylvania, will please copy this, and send their bills to the Railroad Company, 14 Wall street, New-York. 23-17

#### RAILROAD IRON.

500 Tons Railroad Iron, 2 inch by 1/2, with Spikes and Spiking Plates to match, for sale by WM. G. BULL & CO. 74 Wall-st. 26-31p

#### NOTICE

Is hereby given, that an Assessment of Ten Dollars on each share of the Capital Stock of the Boston, Norwich and New London Railroad Company, has been laid payable on the 15th day of August, 1835, at the Office of the Company, No. 52 Wall street, New York, or at the Quinsbaug Bank, Norwich.

THOMAS ROBINSON, Treasurer.

Norwich, July 11th, 1835. 17-16. 1A13

#### RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order car wheels, chairs and knees, and every other description of castings required for railroads. R-17 feb14

#### PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

Railroad Spikes of every description required, made at the Albany Spike Factory.

Spikes made at the above Factory are recommended to be public as superior to any thing of the kind now in use Ship and Boat Spikes made full size under the head, so as not to admit water.

Orders may be addressed to Messrs. ERASTUS CORNING & CO., Albany, or to THOMAS TURNER, at the Factory, Troy, N. Y. sept. 12-17

#### PATENT RAILROAD, SHIP AND BOAT SPIKES.

The Troy Iron and Nail Factory keeps constantly for sale a very extensive assortment of Wrought Spikes and Nails, from 3 to 10 inches, manufactured by the subscriber's Patent Machinery, which after five years successful operation and now almost universal use in the United States (as well as England, where the subscriber obtained a Patent,) are found superior to any ever offered in market.

Railroad Companies may be supplied with Spikes having countersink heads suitable to the holes in iron rails, to any amount and on short notice. Almost all the Railroads now in progress in the United States are fastened with Spikes made at the above named factory—for which purpose they are found invaluable, as their adhesion is more than double any common spikes made by the hammer.

All orders directed to the Agent, Troy, N. Y., will be punctually attended to.

HENRY BURDEN, Agent.

Troy, N. Y. July, 1831.

Spikes are kept for sale, at factory prices, by I. & J. Townsend, Albany, and the principal Iron Merchants in Albany and Troy; J. I. Brower, 325 Water street, New-York; A. M. Jones, Philadelphia; T. Janviers, Baltimore; Degrand & Smith, Boston.

P. S.—Railroad Companies would do well to forward their orders as early as practicable, as the subscriber is desirous of extending the manufacturing so as to keep pace with the daily increasing demand for his Spikes. 172am

H. BURDEN.

#### STEPHENSON,

Builder of a superior style of Passenger Cars for Railroads,

No. 264 Elizabeth street, near Bleecker street, New-York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. J2617

#### RAILROAD CAR WHEELS AND BOXES, AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to. Also, CAR SPRINGS.

Also, Flange Tires turned complete.

J8 ROGERS, KETCHUM & GROSVENOR

#### RAILWAY IRON.

95 tons of 1 inch by 1/2 inch, Flat Bars in lengths of 14 to 15 feet, counter sunk holes, ends cut at an angle of 45 degrees, with splicing plates and nails to suit. soon expected.

350 do. of Edge Rail of 36 lbs. per yard, with the requisite chairs, keys and pins.

Wrought Iron Rims of 30, 33, and 36 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels.

Axles of 24, 26, 28, 30, 32, 34, and 36 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment. A. & G. RALSTON.

9 South Front street, Philadelphia. Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them. 471mcowr

#### SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by

E. & G. W. BLUNT, 154 Water street, corner of Maiden lane.

#### SURVEYING AND ENGINEERING INSTRUMENTS.

The subscriber manufactures all kinds of Instruments in his profession, warranted equal, if not superior, in principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Goniometer, with two telescopes—and a Leveling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes.

WM. J. YOUNG, Mathematical Instrument Maker, No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested. Baltimore, 1832.

In reply to thy inquiries respecting the instruments manufactured by thee, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish thee the following information. The whole number of Levels now in possession of the department of construction of thy make is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repair, except from accidents to which all instruments of the kind are liable.

I have found that thy patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a revolving telescope, in place of the vane sights, leaves the engineer scarcely any thing to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend, JAMES F. STABLER, Sup't of Construction of Baltimore and Ohio Railroad.

Philadelphia, February, 1833.

Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Germanstown, February, 1833.

For a year past I have used Instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these Instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

HENRY B. CAMPBELL, Eng. Philad. German, and Norrist. Railroad

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, AUGUST 8, 1835.

**GRAND JUNCTION RAILWAY.**—We have been favored with the perusal of a manuscript copy of a report of Joseph Locke, Esq., engineer of this important railroad in England, in relation to the form of rail to be used on that road, furnished by the President of that company to the President of the New-York and Erie Railroad Company. It is accompanied by two sheets of drawings, exhibiting in full size the different kinds and shapes of rails used on the Liverpool and Manchester Road, as well as several other kinds of rail now in use in England. It will soon, we are gratified to be able to say, be published in pamphlet form, when we shall take an early opportunity to re-publish it entire in the Journal.

**SAWING MACHINE FOR FELLING TREES.**—It is pleasing to know that ingenuity and enterprise are appreciated and rewarded. Mr. James Hamilton has, we understand, met with an unprecedented sale of the right to use and vend his machine for cutting down trees, having sold a large portion of the Union, in States. Those who desire to obtain the right for its use, should apply soon if they desire to have it at first prices. Mr. Hamilton resides at 157 Crosby street, New-York.

Died, at Columbia, Pa., on Thursday 30th ult., Wm. H. McCURCHEN, Engineer, upon the Pennsylvania Canal, aged 36 years.—[Philadelphia Commercial Herald.]

**THE [WORK GOES BRAVELY ON.—Books** were opened in this city last week, and also in New-Haven and Hartford, Conn., to receive subscriptions to the stock of the New-Haven and Hartford Railroad. The importance of the route, and the favorable report of Mr. Twining, the engineer, caused an unusually large subscription. The amount required was \$1,000,000, and the subscription amounted to over \$5,700,000, or nearly six times what was required. At such a result we are not at all surprised. The enterprising and business character of the inhabitants of the country through which it passes, together with the certainty of its being continued to Springfield, and thence to Worcester, in Massachusetts, thus opening an easy communication with Boston; and the almost, as others believe, but as we believe, positive, certainty of its being extended far up the valley of the Connecticut, at least to Haverhill, in New-Hampshire, and most certainly to Burlington, Vermont, must make the road between Hartford and New-Haven one of the most productive railroads in the country. It cannot be otherwise.

**THE NEW-JERSEY RAILROAD.**—We are happy to see that this great work, so important to the interest of this City, is rapidly progressing. The contractors and men are engaged along the line from Rahway to this city. The road from Rahway to Newark is already graded, and only awaits the laying of rails to perfect it. We learn that it is the intention of the Directors to have it completed to New-Brunswick during this year. Our city will then be in the vicinity of New-York, with all the advantages of cheap living here and all the benefits of the New-York market. We hazard little in asserting, that, upon the completion of this road, enterprise and wealth will not find any place in New-Jersey, or in the vicinity of New-York, with superior advantages to New-Brunswick for their profitable exercise and investment. We also learn that the travelling over the road from Newark to New-York is immense, and that the proceeds of that part of the road will yield a handsome return for the capital required for the completion of the entire route to this city.—[Frederician.]

[From the New-York N. J. Daily Advertiser.]

**MORRIS AND ESSEX RAIL ROAD.**—The Engineer, Judge Wright, having completed his surveys, has laid before the Directors his profiles, surveys, and estimates, which we understand are favorable to the prospects of the Company, and entirely satisfactory to the Board.

Of the several routes surveyed, the two most practicable would each make the whole distance 23 miles, from Morristown to Newark, both passing through Springfield. Leaving Springfield, one of the two surveys named passes through Lyons Farms to the south end of Newark, and the other proceeds north through Orange. The situation of the hills on the route of the present turnpike from Springfield to Newark render that route, it is said, impracticable. On either of these routes the highest grade will not exceed an elevation of 70 feet per mile, for 3 miles on the eastern slope of the Short Hills: 60 feet is the maximum of the rest of the route.

The estimate of the whole cost of putting the road in perfect readiness for the cars is—

By the southern route,	\$217,345
Orange, or northern route,	219,193

including a bridge over the Passaic, at Chatham, which is estimated to cost \$20,000, all told. The cost of the road itself, without a bridge, would therefore be at the rate of 8000 per mile, single track with necessary turn-outs.

That the estimate is a liberal one, may be inferred from the fact that an offer has been made to the Directors of a contract for the whole road at the estimate, with ample security for its fulfilment. But it is believed that the actual cost will fall short of the estimate—the right of way being conceded by the land holders, as it probably would be.

**CANAL BREACH AT PORT BYRON.**—We have been furnished with the following letter, from A. Bart, Esq., Canal Superintendent, to the Comptroller.—[Alb. Argus.]

"Port Byron, Thursday, M., July 30.

"Dear sir—A breach was made in the aqueduct at this place yesterday about noon. We are making great exertions, and hope to have it repaired so as to let in the water to-morrow morning. It will probably cost 300 or 350 dollars to repair it."

The Quebec Gazette, of July 25th, states that Captain Youle, of the Royal Engineers, arrived there on Saturday afternoon, from Montreal, having been ordered from Quebec by the Commander-in-Chief, in compliance with the Address of the committee of the citizens appointed to promote the construction of the Railway to Maine.

Dr. David M. Reese, of New York, has been appointed to the chair of Chemistry, &c., in the Washington Medical College of Baltimore.

Who that has travelled on railroads in this country has not also been annoyed from the same cause? We give the following communication, hoping that a remedy may result from discussion.

[For the American Railroad Journal.]

MR. EDITOR,—I have been very much annoyed while travelling behind locomotive engines, (where wood, coal, or coke, has been used for fuel,) with the dust and cinders flying in my eyes, and soiling my clothes, and am very much surprised that no remedy has yet been attempted or suggested. The following plan I think will remedy the evil:

Place a cylinder of wire gauze, or other material, in a horizontal position over the locomotive, and similar ones over each of the cars. The one over the locomotive may have a wider mouth than the others. Those upon the cars may lie flat; the tops of the cars, forming the lower part of the cylinders, it may not be necessary that they should lap; and it is possible that they will answer when placed some inches apart. As the cinders are emitted from the chimney top, they will be immediately drawn within the cylinders, through which there will be a current of air sufficient to drive them to the rear of the train. The rush of air to fill the vacuum caused by the rapid passage of the cars, will have no effect upon the cinders passing through the cylinders.

Respectfully your obedient servant,  
THOS. SYMINGTON.

N. B.—Letters patent will be taken out for the foregoing invention. T. S.  
Baltimore, July 30, 1835.

The annexed inquiries are of great importance at this period; and we are very desirous that experienced practical engineers should give answers.

[For the American Railroad Journal.]

MR. MINOR,—Please, through the medium of your useful paper, put the following queries to engineers. The answers of practical men might elicit information on an important subject.

1. Would or would it not be better to lay the tracks of railroads wider apart, say six or seven feet?

2. Would it not be better to construct the wheels of railway cars much larger, say five, six, or seven feet in diameter?

3. Would not large wheels be less likely to break stone sills, and bend wooden ones?

4. In the use of large wheels and narrow railways, would it not be better to suspend a part of the burthen under the axle?

5. Could not a railway be constructed upon the undulating principle, as the ground will best suit, say with planes of 50 to 100 feet in the mile ascent and descent, and accompany the cars with a locomotive that should condense atmospheric air into a receiver in descending, which condensed air, used as steam, by reversing the motion of the engine, would assist the propelling power in ascending the next plane? Would not this idea, improved upon, lessen the necessity of such expensive graduation?

The full and explicit answers of engineers to any or all of the above queries, whether as objections or approvals, would gratify  
AN INQUIRER.

We are very much obliged to "A Young Engineer" for the following communication, and hope to hear again from him.

To the Editor of the Railroad Journal:

SIR,—Having been employed in November last to ascertain the number and capa-

city of the steam engines then in use in this city, for the various manufacturing purposes with which our city abounds, and thinking that an abstract would be interesting to many of your readers, I have prepared the following, namely:

Whole number of engines in daily operation, 76\*; aggregate number of horse powers, 858; aggregate number of gallons of water used per day, of 10 hours, 60,385.

Which, in the event of your deeming worthy of an insertion in your columns, will not only be a source of gratification to me, in having added to your useful work, but will be the means of eliciting some further contributions, at no very distant period, from  
A YOUNG ENGINEER.

New-York, July 20, 1835.

[From the American Journal of Science and Arts.]

*On Turnouts in Railroads, with Flexible Moveable Rails.* By THOS. GORTON, Civil Engineer.

At a time like this, when railroads are being rapidly introduced in various parts of the United States, it is believed that any improvement relating to the various parts of their construction will be acceptable to the public.

Up to the present time all turnouts upon railroads, (so far as the writer's knowledge extends,) have been constructed with stiff moveable rails. When these stiff rails are moved round so as to make a communication with the turnout and main line, a rectilinear angle of several degrees is formed by the stiff rail and main line, which subjects cars passing through the turnout to much jar and lateral friction. This friction is so great as to injure both cars and railroad. In a late conversation with Mr. E. Miller, superintendent of machinery on the Portage railroad, he informed me that they proposed using flexible moveable rails for their turnouts. The rail adopted on that road is the parallel edge rail, eighteen feet long, and weighing forty pounds per yard. I understood that the plan of their turnouts was not fully matured, but that it was contemplated to have about three feet of the rail made fast in two heavy chairs, and the other fifteen feet to be sprung into a curved form, when it was desired to pass into the crossing or turnout.

This at once appeared to me to be a decided improvement, in as much as turnouts might be made on this principle, so that cars might pass through them with the same facility as in the curved parts of the main line. In examining the subject, the first requisite is, that the rail at the moveable end should be deflected so as to leave a sufficient distance between the rail of the main line and the fixed part of the turnout. Then, secondly, let the radius of curvature for the turnout be determined; it will be seen that these two requisites determine the length of the moveable rails. These rails may then be laid down in the following manner.

Let about one foot of that part connected with the main line be made fast in a heavy cast iron chair, by a wedge, and by a bolt passing through the chair and rail. The moveable part of the rail

may be supported on chairs; these chairs to rest on cast iron seats, having a ledge on one side for the chairs to slide against when the rail is sprung round into the turnout. The seats consequently must be laid down in the curve form which the rail is to assume in the turnout. If it is thought that the chairs on this part of the rail will work out of place, they may be bolted to it, or secured in some other manner by guides on the seats. The two moveable rails of a turnout should then be connected by two or three stiff coupling bars, to give them permanence, and preserve the proper distance between them. The rails may then be worked by a vertical lever of a suitable length. This lever, with a ball placed upon its top, will serve as an index to persons travelling the road, by pointing out the position of the moveable rails, that the cars may be stopped in time, if the rails are not right.

The result of some calculations for rails of different lengths will now be given, together with the length of a turnout for each kind of rail. These calculations are made for a double track of railroad, the distance between the rails of each track being 4.75 feet, and the distance between the inner rails, including the width of each rail, five feet. But as railroads in general do not differ much from this in outline, the length of a turnout will not be affected much by such difference.

The following table will be understood from the explanation given therein.

Radius of turnout in feet.	Length of moveable rail not including that part in the heavy chair.	Deflection at end of rail in decimals of a foot.	Angle of crossing plate and side of arc at each end of turnout, in feet.	Feet of straight line in the centre of turnout.	Length of turnout in feet.
310.	15 ft.	0.36	7° 37.78	40	115
350.	16	0.36	7° 42.65	35	120
400.	17	0.36	7° 48.75	30	128
410.28	17	0.35	7° 50.00	29.3	129.6
450.	18	0.36	7° 54.84	23	133
500.	19	0.36	7° 60.93	17	139
550.	20	0.36	7° 67.03	11	145

In the above table, fractions of a foot have been omitted in the last two columns, the object being to give sufficient information in a tabular form, from which a comparison of the advantages and disadvantages may be made for turnouts with moveable rails of different lengths, and arcs of different radii. An angle of 7° has been adopted in this table for the crossing plate. Increasing this angle would shorten the turnout but little. It is hardly necessary to mention, that the plan of the turnout proposed here is that of an inverted curve, with a piece of straight line in the centre.

It is believed that a turnout of from 400 to 500 feet radius, with flexible moveable rails, will be found to answer a much better purpose than those in use at the present time. Several important railroads have curves as abrupt as this. On the Baltimore and Ohio railroad there are two sharp curves, one of 337, and the other of only 318 feet radius.

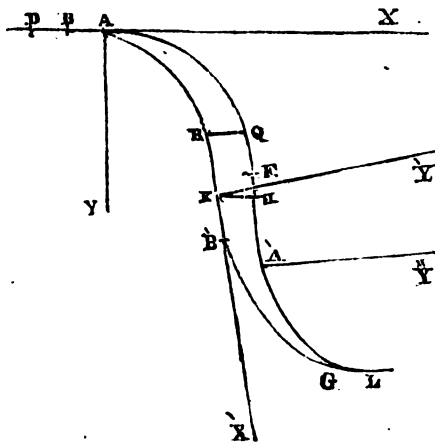

\* From 8 to 12 have been erected since.

[For the American Railroad Journal.]

*On the Location of Railroad Curvatures; being an Investigation of all the Principal Formulas which are required for Field Operations, in laying Curves and Tangent Lines, to pass through Given Points.*  
By J. S. VAN DE GRAAFF.

(Continued from number 24.)

27. The preceding articles, with their obvious combinations, embrace all the cases which can occur in the field, by a method of computation rigorously accurate, and of convenient application. But before closing this part of the subject, the following example will be here given, as a general illustration of the method to be pursued when an alteration is proposed in a line after the completion of a location.

Let D A F A' G L represent a located line having the following character: D A, a tangent; A F, a curve, modulus of curvature  $2^\circ 3'$ , and length 18 chains; F A', a tangent, length 9 chains; A' G L, a curve, modulus of curvature of the part A' G,  $2^\circ 52'$ , and length of the same part, 15 chains. Now, it is proposed to remove the origin A 4 chains back upon the tangent line D A, to a station B; and to lay a curve B R 15 chains, with the same modulus of curvature,  $2^\circ 3'$ ; and it is required to know what would be the direct distance R Q between the two curves from the point R. And if a tangent R X' be laid from the point R, it is also required to know the proper position in that tangent line, for the origin B', and the necessary modulus of curvature, in order to trace a new curve B' G in such a manner as to pass again into the original line G L with a common tangent at the station G.

Because B R = 15 chains, and B A = 4 chains, the difference is 11 chains, and the curve A Q will therefore obviously contain more than 11 chains when R Q is normal to the tangent R X'. Hence, taking the station Q at the extremity of 13 chains, the data for computing the line R Q by means of (XXV.), will be,  $T' = 2^\circ 3'$ ,  $n = 13$ ,  $m = 15$ , and  $\alpha = +4$ ; or,  $2nT = 53^\circ 18'$ , and

$$2mT = 61^\circ 30'; \text{ and therefore } w = \frac{-0.1022}{-0.0256}$$

$$-4 \times \frac{.87882 - .80178}{.03577} + 16 \left\{ \frac{1}{2} \right\} = (4.00$$

$$-4 \times 2.153 + 16) \frac{1}{2} = \sqrt{11.288} = 3.38$$

$$\text{chains nearly} = R Q. \text{ And by (XXVI.),}$$

$$\cos. P = \frac{1.076 - 4}{3.38} = -.8651; \text{ that is,}$$

$P = 210^\circ 6'$ . Hence, the angle Q R X' will evidently be expressed by  $2mT + 210^\circ 6' - 180^\circ = 91^\circ 36'$ ; which being nearly a right angle, proves that 13 integer chains in the curve A Q, corresponds most nearly with a true normal line Q R. The length of the line Q R furnishes the data by which to

judge of the situation of the ground at the point R.

The origin, and curvature of the new curve B' G, will now be investigated by means of (XVII.) and (XVIII.) Let any arbitrary point K be selected for the origin of a system rectangular axes K X', K Y'; and compute the values of the co-ordinates A' H', H' K, of the origin K, taken with reference to the rectangular axes which have their origin at A'.

In such a case as the present, it would be most convenient to take the point K coinciding with the station R; but in order to retain the results given in a former example, take R K = 12 chains; and the values of the required co-ordinates will then be, A' H' = +1.37 chains, and H' K = +1.58 chains.

The co-ordinates of the point G, taken with reference to the axes K X', K Y', may now be computed by means of (XXI.), after the co-ordinates of the same point, taken with reference to the axes at A, have been determined by (VII.) To find these latter co-ordinates, the given data are,  $T = 2^\circ 52'$ , and  $n = 15$ ; or,  $2nT = 86^\circ$ . Hence, by

$$(VII.), x = \frac{.99756}{.10002} = 9.98 \text{ chains, } y = \frac{.93024}{.10002}$$

$= 9.30$  chains. Now, the data necessary for computing the new co-ordinates by means of (XXI.), are,  $\alpha = +1.37$ ,  $\beta = +1.58$ ,  $z = +12^\circ 18'$ ,  $x = 9.98$ , and  $y = 9.3$ . Hence,  $x' = 10.88 \times .2130 + 11.35 \times .9770 = 2.32$  +  $11.09 = 13.41$  chains,  $y' = 10.88 \times .977 - 11.35 \times .213 = 10.63 - 2.42 = 8.21$  chains. The inclination of a tangent at G, to the tangent F A', is expressed by  $30 \times 2^\circ 52' = 86^\circ$ ; and therefore the inclination of a tangent at G, to the tangent R X', is expressed by  $86^\circ - 12^\circ 18' = 73^\circ 42'$ .

The given data by which to compute the position of the new origin B' by means of (XVIII.), will therefore be  $X = 13.41$ ,  $Y = 8.21$ , and  $D = 73^\circ 42'$ ; that is,  $\alpha = 8.21 \times 1.334 - 13.41 = 10.95 - 13.41 = -2.46$ . The required origin B', of the new curve B' G, will therefore be situated 2.46 chains in advance of the selected point K; that is, the length of the new tangent R B' is 14.46 chains. By (XVII.),  $\sin. T = \frac{.71933}{16.42} = .04381$ ; or,  $T = 2^\circ 30' = \text{modu-}$

lus of curvature of the required new curve B' G.

#### SCHOLIUM.

When the curves under consideration are long, and also embrace portions of circumferences greatly exceeding  $20^\circ$  or  $30^\circ$ , the trigonometrical formulas investigated in the foregoing articles become of the utmost importance in the field. But there are several well known approximative formulas which will sometimes be found useful auxiliaries in the first location of a line where short and frequent curves are introduced; and they will also very often be convenient when certain alterations are proposed in a known line, and a new line is required to be selected by computation. It is therefore the design of the remaining part of the present inquiry to show how those approximative results may be easily deduced from the rigorous formulas already given.

28. By means of (VI.), we have  $y = \frac{\sin. n^2 T}{\sin. T}$ ; and therefore the quantity  $n^2 \times$

$\sin. T$  will always exceed the value of  $y$ . Hence,  $n^2 \times \sin. T$  will express the value of some ordinate oblique to the axis of  $x$ .

Let this oblique ordinate be denoted by K; and the following expression will obtain:

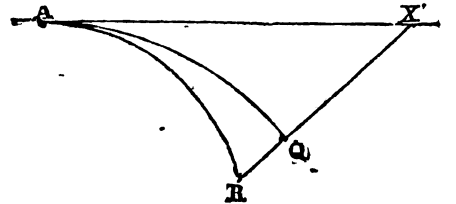

$$K = n^2 \cdot \sin. T. \text{ (XXXVI.)}$$

But by putting  $q = 0.01745$ , which is the length of an arc of one degree, to a radius unity, and supposing the angle T to be

measured in degrees, and decimal parts of a degree, the result will be, that  $q \times T = \sin. T$  very nearly. The value of the oblique ordinate K will therefore be nearly expressed as follows:

$$K = qn^2 T. \text{ (XXXVII.)}$$

29. Suppose T and T' to denote the respective moduli of curvatures in degrees of two curves A Q and A R, which are laid from the same point A, and upon the same tangent line A X; and let each curve contain an equal number of chains represented by  $n$ . It is proposed to find an approximate value for the distance Q R.

Let Q X and R X be the two oblique ordinates whose values are expressed by  $qn^2 T$ , and  $qn^2 T'$ , respectively. If, then, those two ordinates be supposed to coincide with each other, which will not be far from the truth, then their difference in length must express the required distance Q R. Hence, taking  $w$  to represent the line Q R, the following formula is evidently the result:

$$w = qn^2 \cdot (T - T'). \text{ (XXXVIII.)}$$

The formula thus obtained is an exceedingly near approximation of the true length of the line Q R, when the curves A Q and A R do not contain more than  $20^\circ$  or  $30^\circ$  each; but its application in the field is confined to that particular case only in which those two curves contain each the same number of chains. And although the length of the line  $w$ , as thus computed, will not differ so much from the true quantity as to produce a material inconvenience in the location of a line in a slightly undulating country, even when the two curves embrace portions of circumferences greatly exceeding  $20^\circ$  or  $30^\circ$ , yet, in such cases, if the result were even rigorously true, a knowledge of the length of the line  $w$  will be of little use in the field when the obliquity of that line remains unknown. The formulas (XXIII.) and (XXIV.) must, therefore, in such a case, be resorted to, in order to discover the true position of one of the curves when the other is given; but when those two curves each embrace only a small part of the whole circumference, it will be sufficient in practice to measure the line  $w$  as a normal to either curve, in which case the expression (XXXVIII.) will be highly useful.

It is sometimes required to find the modulus of curvature of one of the curves, when the other curve and the line  $w$  are given data; in which case the following formula obtains:

$$T' = T \pm \frac{w}{qn^2}. \text{ (XXXIX.)}$$

This expression is immediately derived from a transposition of the one preceding.

Three examples will be now given, the first of which will be a case where the formula (XXXVIII.) is not at all applicable; the second will explain a case where that formula can not be used alone with advantage; and the third will show an instance in which the same formula will be very useful in the field.

Example 1. Let a curve whose modulus of curvature is  $2^\circ 45'$ , be traced 20 chains of 100 feet each, from a given point and from a given tangent line. Now it is proposed to lay another curve from the same

origin, and from the same tangent line, and whose modulus of curvature is  $3^\circ$ . How far would this latter curve pass from the extremity of the former?

Here, by (XXXVIII.),  $w = .01745 \times 400 \times \frac{1}{4} = 1.75$  chains = 175 feet = the required distance as determined by the approximative method. But this result is too far from the truth to be of any practical utility, as will appear from the following accurate calculation. Taking the extremity of the 19th chain for the termination of the new curve, the given data in (XXIII.) are,  $\alpha = 20$ ,  $m = 19$ ,  $T = 2^\circ 45'$ ,  $T' = 3^\circ$ , and  $\text{Sin. } 110^\circ = .93969$   
 $\alpha = 0$ ; that is,  $x = \frac{2 \text{ Sin. } 2^\circ 45'}{1 - \text{Cos. } 110^\circ} = \frac{.0960}{1 + .34202} = 9.79$ ;  $y = \frac{1.34202}{.0960} = 13.98$ ;  $x' = \frac{\text{Sin. } 114^\circ}{2 \text{ Sin. } 3^\circ} = \frac{.91355}{.1047} = 8.73$ ;  $y' = \frac{1 - \text{Cos. } 114^\circ}{2 \text{ Sin. } 3^\circ} = \frac{1 + .40674}{.1047} = 13.44$ ; or,  $x - x' = 1.06$ , and,  $y - y' = 0.54$ . Hence,  $w = (1.06)^2 + .54^2 = (1.1236 + .2916) = \sqrt{1.415} = 1.19$  chains = 119 feet = true distance from the extremity of the given curve, to the station at the termination of the 19th chain in the proposed curve.

(To be continued.)

[For the Railroad Journal.]

#### PROBLEM.

To determine a grade, which will produce the same consumption of power, in a rectilinear railway, as is produced by a level curvilinear track of 800 feet radius, with a given degree of motion.

Solution.—Let  $V$  denote the velocity of the car in feet per second;  $R$  the radius of curvature in feet;  $W$  the weight of the car;  $m$  the distance in feet, through which a heavy body will fall in the first second of time near the earth's surface;  $G$  the required grade per mile in feet.

Agreeably to the laws of centripetal forces,  $\frac{V^2}{2mR} \times W =$  the centrifugal force of the car; and which expression will consequently exhibit the lateral pressure on the side of the rail very nearly. Hence, agreeably to the laws of friction,  $\frac{V^2}{8mR} \times W =$  that part of the moving power which is consumed in consequence of centrifugal force.

From the science of mechanics we therefore have,  $5280 : G :: W : \frac{V^2}{8mR} \times W$ , and consequently,  $G = 660 \times \frac{V^2}{mR} = 41 \times V^2 R$  nearly.

From the above formula it is easy to compute the following table, exhibiting the grades which are equivalent to a curve of 800 feet radius, with different degrees of motion.

Radius of curvature in feet.	Velocity of the car in miles per hour.	Corresponding grade in feet.
800	2	0.440
800	4	1.760
800	8	7.040
800	12	15.840
800	20	44.000

[From the N. Y. Mechanics' Magazine.]

MR. BURDEN'S SPIKES. — The public has already had the means of knowing that the above named enterprising individual invented, some years since, a machine for making spikes of wrought iron, chiefly for the purposes of being used in constructing ships and railroads; but their value, compared with other spikes, seems to be but very sparingly known. These spikes, to any competent judge, will show themselves to be far superior to any spikes ever manufactured, or which can be manufactured for the above purposes, for the following reasons. The iron being selected by Mr. B. himself, and in large quantities of the first quality, no other being used, its uniform excellence must infinitely surpass that of common spikes, which are made of such small lots of iron as come to hand promiscuously; the body of these spikes being of exactly even and uniform size, and without hammer strokes, when once entered they have no tendency to split the wood, and, having a square chisel shaped edge, they cut their passage instead of forcing it.

But Mr. B. is emphatically an experimentalist, and he wished to test the comparative value of his spikes by some precise data. He wished to ascertain first with what degree of safety his spikes might be driven into wood without splitting; second, what was the tenacity of the iron; and third, what power it would require to draw them out.

To test the first point, he took a piece of seasoned white oak joist, 3 by 6 inches, and sawing off 3 inches, produced, of course, a piece 3 inches square and 6 inches long, but with the grain running crosswise. In one end of this block, he entered, without boring, the point of a spike 5 inches long, with the edge of its point across the grain, and drove in the whole length without splitting the block.

To ascertain the second and third points, he drove another and similar spike into a similar block, leaving its head a little distance out, and securing the block in a firm situation, and gripping the head by a strong instrument similar to a pair of wire tongs, he suspended to the tongs 100 56-pound weights, equal to 5600 pounds, and these neither breaking the spike nor drawing it out, he took a sledge and struck forcibly upon the apparatus attached to the head of the spike, when it drew out and left the spike and the wood unbroken.

These experiments were made at the store of Messrs. I. & J. Townsend, in this city, in presence of the President and Directors of the Albany and Schenectady Railroad Company, and if they do not remove all doubts as to the superiority of these spikes for ships and railroads, I know not what would. S. B.

Albany, June 15, 1835.

ARITHMETIC BY MACHINERY.—A cabinet-maker of Milan has invented a machine with cylinders, which executes any sum in the first three rules of Arithmetic, for which the Institute of Milan has awarded him a gold medal.

[From the London Penny Magazine.]

Lead. — The appearance of this substance in its metallic state is undoubtedly familiar to every one. It is one of the most useful of mineral substances, and forms one of the most valuable products of the mines of Great Britain. Its specific gravity is considerable, being more than eleven times the weight of an equal bulk of water. It is malleable, and with ease may be reduced into very thin plates; but it is liable to crack under the hammer. It is so far ductile as to be capable of being drawn into wire  $\frac{1}{16}$  part of an inch in thickness, but its tenacity is very low; for a wire of that diameter breaks with a weight a little exceeding eighteen pounds. As it possesses no elasticity, it is incapable of compression, and differs in that respect from all the other ductile metals, which diminish in volume, and, consequently, increase in density, under the hammer; but lead has the same specific gravity when it is simply melted as when it is beat or rolled out into plates. It is the least sonorous of all the metals. It is easily fusible, melting at  $612^\circ$ , or a heat less than three times that of boiling water; but not so easily as tin, which melts at the temperature of  $442^\circ$ . When first melted, or when cut, it has a brilliant lustre; but this shining surface, however, is soon tarnished by attracting oxygen and carbonic acid from the air: but this coating of carbonated oxide, once acquired, protects it from further change. Water has no action upon it: and hence its usefulness for cisterns and pipes. When exposed to the continued action of a stream of hot air, it rapidly acquires oxygen, and is converted into a substance which is called "litharge."

Lead has been sometimes found in the pure, or native state; but very rarely, and always in small quantity. It is one of the metals which is found in the greatest variety of combinations: but there is only one kind of ore which is very abundant; the rest are chiefly known as objects of interest to the mineralogist; many of them afford very beautiful specimens for the cabinet. The common ore is a combination of eighty-six parts of lead and fourteen of sulphur, and is called usually by the name of *Galena*, or sulphuret of lead. It very often contains silver, and in sufficient quantity to pay the expense of a process for separating it. That of the north of England contains from 2 to 24 ounces of silver to the ton, and the average quantity is  $11\frac{1}{2}$  ounces. The galena of the mine Huel Pool, in Cornwall, yielded 60 ounces; of Guarnock Mine, near Truro, 60 ounces; and a mine near Beeralstone, in Devonshire, yielded galena so rich as to give 135 ounces of silver to the ton. A great proprietor of lead mines in the north of England had a splendid service of plate made of the silver so separated from the lead ore.

In geological position, lead is most abundantly met with in the lower strata of the secondary sedimentary deposits, especially in the carboniferous limestone. It is found also in considerable quantity in the strata below these, in the grauwacke, clay-slate, mica-slate, and even in gneiss, which is the lowest of the stratified rocks. It is found also, but more rarely, in the unstratified rocks, both in granite and in trap; but in all the instances that have been mentioned, the granite and trap have always been associated with stratified rocks containing lead ore. It is occasionally found in the coal-measures, but not hitherto in any of the strata above the coal. Galena, next to pyrites, or sulphuret of iron, is the most common of the metallic ores, and it is found in almost every country of the globe; but

There are large tracts without any deposits of it in sufficient abundance to be worked.

England produces annually nearly three times as much lead as all the other countries of Europe put together. The chief mines are in the north of England, in Derbyshire, North Wales, and Devonshire, on the borders of Cornwall. The great seat of the north of England mines is that high district around the mountain of Cross Fell, where the counties of Northumberland, Cumberland, Westmoreland, the North Riding of Yorkshire, and Durham, meet, as it were, in a central point, and from which they radiate. The mines first become of importance on Muggleswick Moor, on the borders of Northumberland and Durham, about twenty-seven miles from the east coast of Sunderland, and at Blanchland, on the river Derwent, a little to the west of Muggleswick; and they continue to the summit of Cross Fell. Aldstone Moor, in Cumberland, and Dufton, in Westmoreland, are important places in this district; and there are mines in Weardale, Teesdale, Allendale, and Askendale. Mr. Forster reckons that, in this part of England, there are no less than 175 lead mines, which either have been or are now worked. The prevailing rock is the carboniferous limestone,—that great deposit which lies immediately under the coal strata in most parts of England. It is associated with strata of sandstone and slate; and there are about twenty different beds of limestone which the miners distinguish by different names. The series of strata at Aldstone Moor, according to a section given by Mr. Winch, consists of about sixty alternations of slate, sandstone, and limestone, in 159 fathoms, or 854 feet. The whole are covered by the coarse sandstone commonly known by the name of "millstone grit." The above dimensions are only a part of the strata where they are bored through in sinking the well, or shaft of a mine; but if we include the whole deposit from the upper surface of the old red sandstone, on which the series rests, we obtain a total thickness of nearly 2800 feet. Beds of trap, one of which is particularly designated the "Whin Silt," a miner's term, are interposed between the strata in several places. The lead ore occurs in veins, which traverse the strata in various directions, and in many irregular ways, sometimes being very slender, at other times extending to great widths. They are usually of larger dimensions in the limestone than in the slate and sandstone: one vein, which is seventeen feet in a limestone stratum, contracts to three feet in the sandstone below; and they are always much richer in ore, even in proportion to their magnitude, in the limestone. That part of the series which is richest in lead does not exceed 300 feet. The mineral substances which accompany the ore, forming what is called the "vein-stone," are calcareous spar, fluor spar, quartz, and a few others of less frequent occurrence. The mines in this part of England have yielded, of late, on an average, about 25,000 tons of lead annually, which is more than one-half of the whole produce of Great Britain; and of that amount nearly a third is obtained from the mines belonging to Greenwich Hospital. In the year 1831, 28,000 tons were raised from the mines of Cumberland, Northumberland, and Durham.

The lead mines of Derbyshire are situated in the north-western part of the country, extending as far south as the neighborhood of Matlock. That district is almost wholly composed of the carboniferous limestone, which is surrounded on all sides by the

millstone-grit that lies above it. The limestone is very much disturbed in its stratifications, and is intersected by dikes and beds of trap. There are limestones of various qualities and colors in the series, chiefly of a grey and fawn color, but sometimes quite black; and several of the beds being of a texture which receives a good polish, they are used as marbles for architectural and ornamental purposes. The limestone-beds contain numerous great caverns, which are often visited by travellers. The ore is galena; but it contains in general too little silver to repay the cost of extracting it. The vein-stones that accompany the lead ore are usually calcareous spar and fluor; the latter being the substance which is so generally known by the name of "Derbyshire Spar,"—a beautiful mineral, and capable of forming handsome vases, and such like ornaments. This mineral is a compound of lime with a peculiar acid, which, from having been first found in it, was called "fluoric acid." Farey, in his 'Mineral Survey of Derbyshire,' enumerates no less than 280 mines, which had been, or were then (1811,) working.

Next in importance to the mines of the north of England, those in North Wales, in Flintshire, and in Denbighshire, are the most productive: a small quantity is raised in Shropshire, and in the neighborhood of Tavistock in Devonshire. Lead ore has been found in different places in the Isle of Man, and mines were worked there in the reign of Henry IV.; they were even in some activity as late as the early part of the last century, but they are now almost given up. It is found in the counties of Down and Wicklow in small quantities, sufficient, however, to be worth working. The lead mines of Scotland are more productive. The most important are those situated in the grauwacke, or slate-rocks, composing the range of hills which runs quite across the south of Scotland, from St. Abb's Head, north of Berwick, and in that part of it called Lead Hills and Warlock Head, on the borders of the counties of Lanark and Dumfries, north-east of Sanquhar. These mines were discovered in the year 1540, and have yielded large revenues to the proprietors ever since. The veins traverse the grauwacke rock from north to south, and very considerably in thickness, some of the principal ones being from four to ten feet in width. At one time, the Susannah vein exhibited a mass of solid ore no less than fourteen feet thick; this was probably a junction into one of several small veins. Some years ago, the mines of Lead Hills and Warlock Head together yielded about 2400 tons annually. Lead has been wrought at Tyndrum, in Argyleshire, where the ore is found in a bed of quartz, which is part of a series of strata of the primary rock, mica slate; and also at Strontian, in the same county, where the galena traverses gneiss, the oldest of the primary strata. The produce of the different lead mines in Scotland was at one time estimated to amount to 4800 tons, but it has, of late years, fallen off very considerably. Mr. Taylor, in his 'Records of Mining,' gives an account of the quantity of lead raised from the mines of Great Britain in the year 1828, which, he says, was the result of a careful inquiry among those best acquainted with the subject. It is as follows:

	Tons.
North of England Mines -	26,700
Derbyshire and Shropshire -	4,800
Devonshire and Cornwall -	2,000
Flintshire and Denbighshire -	12,000

Scotland -	1,000
Ireland, Isle of Man, &c. -	500

47,000

Five years prior to this, the whole amount was only 36,000.

*Method of obtaining the Metal from the Ore.*—The ore, after having been properly broken, and separated as much as possible from the vein-stones, is roasted in a furnace, with a small quantity of coal, in order to expel the sulphur, and any other volatile matter which it may contain. After undergoing this process, it is taken to a blast furnace, of a peculiar construction, called an "ore-hearth," where, by a powerful heat, the ore is melted, and the metal separated from the dross, or slag, which swims on the surface; the mass being frequently stirred, to facilitate the separation, for a period of from twelve to fifteen hours. There are various manipulations during the process, and these, together with a supply of fuel and of lime (which is added to facilitate the reduction), are modified according to the nature of the ore, and require much skill and tact on the part of the workman. The slags, still containing a portion of lead, are subjected to another process of smelting with coke in another furnace. In all these operations a considerable quantity of the ore is volatilized, and condenses in the chimneys of the furnace: this, which is called "smelters' fume," is collected from time to time, and the lead is extracted from it.

The quantity of silver contained in the greater part of the lead ore raised in the north of England is sufficient to render its extraction profitable. The separation of lead and silver is effected by the different degrees of attraction which the two metals have for oxygen, the silver remaining unaltered, when exposed to the air of the atmosphere at a high temperature; whereas lead, under the same circumstances, becomes rapidly converted to a protoxide;—that is, becomes a new substance, composed of lead and a minimum quantity of oxygen, and which is commonly known by the name of "litharge." The lead to be refined is placed in a furnace so constructed as to admit of the ready separation of the litharge as it is formed; it is melted and farther heated till it becomes of a bright red, and then the blast of air is made to pass over it. This not only supplies the oxygen, but is sufficiently strong to sweep away the oxide as it is formed, by which means a fresh surface of the melted lead is exposed: more lead is supplied, from time to time, as the operation proceeds, and, at the end of the process, a cake of silver is found at the bottom of the furnace. The lead is recovered from the litharge, by a very simple process, which consists in mixing it with coal, and exposing it to a strong heat: the carbon of the coal has a stronger attraction for oxygen than lead has, and therefore separates it from the litharge, leaving the pure metal, which is run out into moulds to form the pigs, or bars, in which shape it is brought to market. This process of extracting the silver from the lead was not introduced in the north of England mines till the reign of William and Mary.

The working of lead mines in Great Britain dates from a remote period. The mines in Derbyshire, it is supposed, were wrought in the time of the Romans; the proofs of which are derived from blocks or bars of lead which have been found with Roman inscriptions upon them. A bar of this kind was discovered on Cromford Moor in the year 1777, and the interpreta-

tion of the inscription which has been given is the following: "The Sixth Legion inscribe this in memory of the Emperor Adrian." Another bar was met with near Matlock in 1783, the inscription of which has been translated as follows: "The property of Lucius Aruconius Verecundus, merchant of London." The Saxons and Danes, it is supposed, were also engaged in working the mines of Derbyshire, from the designation of the Odin Mine, at Castle-ton, which it is conjectured was so called from the name of the northern deity.

**Uses of Lead.**—Besides the various purposes to which it is applied in its pure state, lead is employed in many different ways in combination with other substances. The sulphuret of lead—that is, the common ore, galena—is made use of, without any previous preparation, as a glazing for coarse pottery. The protoxide, or litharge, enters largely into the composition of flint-glass, which it renders more fusible, transparent, and uniform. Combined with another proportion of oxygen, it forms *Red Lead*, which is also used in the manufacture of flint-glass, and as a paint. *White Lead*, which is so extensively used as a paint, is a combination of the metal with oxygen and carbonic acid. *Sugar of Lead*, which is used very largely in several manufactures, particularly in calico printing, and also in medicine as an external application, is a compound of lead and acetic acid, or vinegar. It is so called from having a remarkably sweet taste: it is well known, as well as most of the combinations of lead, to be a deadly poison.

Of the 45,000 tons of lead which may be estimated as the average produce of the mines of the United Kingdom, about one-third is exported. In the year ending January 5, 1833, the exports were as follows:

	Tons.
In pigs, and rolled, and shot, -	12,181
Litharge - - - - -	433
White Lead - - - - -	652
Red Lead - - - - -	396
Lead Ore - - - - -	236

Total - - 13,898

The countries to which that quantity was exported were,—

	Tons.
United States of America - - -	4,896
East Indies and China - - -	2,930
Russia and Sweden - - -	1,951
Germany - - - - -	634
Brazil - - - - -	526
West Indies - - - - -	514
British North America - - -	480
The Netherlands - - - -	456
Cape of Good Hope and Africa -	435
New South Wales - - - -	223
Italy and the Levant - - -	226
Spain and Portugal - - -	226
Other places in lesser quantities	351

Total - - 13,898

No species of property, perhaps, has undergone so great a deterioration in so short a time as that of lead mines. In the year 1809, the market-price of lead in bars was £31 3s. per ton; and, according to the tables given by Mr. Macculloch in his 'Commercial Dictionary,' the average price for the ten years ending 1810 was £27 14s. 6d. It rose to £31 in the year 1814, when speculations at the close of the war raised the value of many of our native products; but the average of the ten years ending 1820 was £23 6s. 6d. A sudden fall took place five years afterwards, for in 1825 the price was £25 6s., and the following year it fell to £19; and it kept falling

till 1832, when it was down to £13 10s. From that extreme depression it has partially recovered, the present market price being about £18 per ton. This extraordinary fall was occasioned by a sudden increase of supply from the lead mines of Spain. These mines are situated in Andalusia, partly in a range of mountains to the north of Jaen, near Linares, but chiefly in another range which lies between Jaen and the city of Granada, and on the southern slope of them. We know little about these mines beyond their locality, for the geology of Spain is as yet very imperfectly understood. Bowles, who wrote in the year 1776, describes the mines to the north of Jaen to have been worked by the Moors, and says that the mountains are pierced by shafts in all directions; that there are two great veins which pass through granitic rock, which vary considerably in richness; and that at one time one of the mines produced in a year more than all the lead mines of Saxony together had done in twelve years. But it is the mines in the mountains of Granada from which the recent great supply has been obtained. The ore lies near the surface, and is therefore obtained without much exercise of skill, or expense of labor and machinery. Mr. Witham says, that "the metalliferous limestone of the south of Spain is so rich in galena as to furnish, even in the present imperfect state of mining in that country, about 20,000 tons of lead annually. France has some lead mines in Brittany, Languedoc, Alsace, and other parts of her territory, but imports the greater part of her consumption, and chiefly from Spain; England having sent only 70 tons to France out of the 13,898 exported in 1832. There are many lead mines in Saxony, Bohemia, Silesia, and other parts of Germany. Although the exports to the United States from this country are so considerable, they are not without ores of that metal in their own country. The mines are situated in Pennsylvania, Massachusetts, and on the Fever and Missouri river in the Western States; the richest being in the latter country. The total produce in 1829 exceeded 6000 tons.

[From the New-York American.]

**COOKING BY GAS.**—This new application of Gas seems to us of great promise, for economy, comfort and safety. We had heard nothing of it until a few evenings ago, on the invitation of Mr. L. Suydam, President of the Manhattan Gas Works, we had an opportunity, at his house, both of seeing the process of cooking, and verifying the fact that what was thus cooked, was "well done," even though not "quickly done."

The apparatus is of great simplicity. A circular or elliptical burner of such dimensions as may be needed—in a large family several of different dimensions would be required—is constructed, pierced with numerous and very small apertures, so that all the gas that passes may certainly be consumed. In the centre of the circle, is a permanent perpendicular spit, on which the joint to be roasted is impaled, a sheet iron funnel-shaped chimney, large enough at the bottom to include the lights, and tapering upwards so as to concentrate and reflect the heat, is then placed over the whole, and the cook may go about any other business, for the next two or three hours, fully assured on coming back at the end of that time, of finding the meat well cooked. But this is not all. Over the funnel shaped chimney is placed a large tin vessel divided horizontally into two compartments—the lower one serving as a kettle to boil water, the upper as a vessel in which to boil meats or vegetables,

and the same fire and the same time required for roasting, will also suffice for boiling the water, and cooking the vegetables. The cost for fuel of such a fire, as we saw, by which a 12lb piece of beef was roasting, was stated by the superintendent, Mr. Barlow, at two cents an hour—or six cents for the whole period for cooking dinner—add to this the further economical advantage, that you only light your fire when you want it, and extinguish it the moment it has fulfilled its purpose, and we have a strong argument on the score of cheapness.

It is obvious that any number of these burners may be arranged—all to be supplied by one main leader—and as the cost of these fixtures is small, and only the gas actually used is paid for, it would be expedient always to have several of them.

Of course the value of this new application of gas depends upon proper care in the use of the apparatus, and on the part of the company, in the preparation and purification of the gas. As to the first, the whole thing is so simple, that except through wilfulness there could be no mistake, and as to the purification of the gas, the interest of the company would be so great in seeing to that, as upon its freedom from smell and brightness in burning, its general use would essentially depend—that little need be apprehended on that score.

Upon the whole we confess ourselves amazingly taken with this kind of fuel—and recommend to our friends to ascertain, at the works of the Manhattan Gas Company, the cost, and the advantages particularly in hot weather, of such kitchen fires!

**HYDROSTATIC PRESSURE ON THE EYES OF WHALES.**—Admitting a cubic foot of fresh water weighs sixty-five pounds, and the same measure of sea water, sixty-six and a half, the pressure on the bodies of marine animals must indeed be great. Were a cubic foot of the latter to weigh exactly sixty-six pounds, at the depth of 8400 feet, the pressure must be the enormous weight of 554,400 pounds. Whales have occasionally run out fourteen warps of a hundred fathoms each, which, if the descent be perpendicular, is just equal to 8400 feet. However, it is probable that this course is usually at an inclination of between seventy and eighty degrees from a vertical line, but arriving nevertheless, at depths much beyond ordinary soundings. Supposing the eye of the whale exposes to the water six square inches in its entire superficies, when the monster dives to the depth to which it has been assumed that he has the power of going, the hydrostatic pressure on the eye will be equal to 23,100 pounds. Six square inches are the twenty-fourth part of a square foot; and at 8400 feet, the weight being 554,400 pounds, it follows, therefore, that the eye resists the force or pressure of just 23,100 pounds.

When a tightly corked bottle is sunk one hundred fathoms, at sea, the cork has invariably been forced in, and the bottle found full of water, when brought to the surface. If the cork be capped with sealing wax, on coming up it will be inverted, the sealed end being downward. On the other hand, if nothing is applied, then the cork will generally have a horizontal position. These experiments, however, have been so frequently made, that they have ceased to be interesting to philosophers.—[Sc. Tracts.]

**REMARKS.**—The communication and table from Mr. Green, I think, cannot fail to be acceptable to cotton manufac-

An English penny, placed out at compound interest, at the rate of 5 per cent. at the birth of Christ, would, in the year 1786, have produced the enormous sum of £90,991,000,000,000,000,000,000,000,000 sterling, which would make about 1100 millions of globes the size of our earth in solid gold. At single interest it would produce only 7s. 6d.—[Boston Mercantile.]

[From the London Penny Magazine.]

The whey that drained from the curd, during the process of cheesemaking, is put into trendles (a sort of tub) and suffered to remain till the next day, when it is skimmed. From this whey butter is made, and the residue is given to pigs. The

rennet is made by mixing salt and water till it will support an egg, and then boiling it half an hour. When it is cold, four calves' stomachs are put to a gallon of the brine, with bay leaves and slices of lemon. In six weeks it is fit for use.

For single Gloucester cheese, the vats, which are made of elm, are thirteen inches in diameter, and about two inches and a half in depth: for double Gloucester cheese, the same diameter, and twice, or more than twice the depth. All the dairy utensils, after being used, are washed with tepid water, and then scalded. In making the double Gloucester cheese, and those that are called "truckles," the same method is pursued, except that more care is used in pressing the curd into the vats, which, for such cheeses, have three perforations to let the whey drain off; and bandages of cheese-cloth are put round when the curd is above the vat. Sage-cheese is made by pounding sage and straining the juice into a pail of milk, to which rennet is then added. The same process is observed as for other cheese till the time when the warm whey should be poured upon it, when it is broken up with as much of the simple curd as the milk-maid considers necessary, and treated as other cheese. To make the richest cream-cheeses, the thickest cream must be taken, and put, with a little salt, into a straining-cloth, which is hung up twelve hours, in order that the whey may drop from it. When it is taken from the cloth, it is put between two pewter-plates, with a weight on the upper one, and turned daily during five or six days. These cheeses can only be made in this manner in warm weather. The milk that the cows give when they are first turned into the fields in the spring, and when they are afterwards pastured in fields that have been newly mown, yields nearly as much curd again as at any other period; and it is also much richer. The principal season for making the thin cheese is from April to November; and that for making the thick, May, June, and the beginning of July.

In different districts, the produce of cows differs very much; but, in the Vale of Gloucester, from  $3\frac{1}{2}$  to  $4\frac{1}{2}$  cwt. per cow is considered a fair annual average return. The same cow, on different pastures, will yield milk of very different qualities; from one will be made rank and unpleasant cheese, while the other will be fine and rich. An estimate of the profit and expenses of a farm for twenty cows can be, from the continual variation in the state of the times and local circumstances, of course only an approximation towards the truth. But the following, made in the Vale of Gloucester in 1835, where the land is rich and excellent, is as accurate an annual average statement as the nature of the subject will admit:

Rent of 40 acres, at 50s., for pasture.....	£100	0	0
— 20 acres for hay.....	50	0	0
— 2 acres of arable, for potatoes....	5	0	0
Making hay, 12s. an acre.....	12	0	0
Carrying and rickling.....	2	10	0
Expenses of raising potatoes and seed.....	15	9	0
Tithes, 2s. 6d. in the pound.....	27	2	6
Poor and other rates, 3s. 9d. in the pound..	29	3	11
Dairymaid, 7l. a year (besides board).....	7	0	0
Dairyman, at 7l. a year (besides board)....	7	0	0
Wear and tear of dairy utensils.....	10	0	0
Stk.....	30	0	0

Anatto, 1s. a-pound.....	1	0	0
Rennet and paint.....	1	4	0
Interest of money laid out in stock and im- plements, reckoning each cow at from 8l. to 10l., and chance of loss.....	20	0	0
Profit.....	87	11	7
	£366	0	0

Cheese, 4 tons, at 4 cwt. each cow, and at 44s. per cwt.....	£176	0	0
Value of whey.....	20	0	0
Pasture of colts and sheep.....	20	0	0
Profit of calves.....	30	0	0
Butter.....	90	0	0
Pigs.....	5	0	0
Potatoes.....	25	0	0
	£366	0	0

The capital necessary for the purchase of stock for such a farm would, according to present prices, be about 300l.; but as it is not prudent that the whole of the capital should be expended, a man who had only that sum should take a smaller farm, and reserve a part for the payment of work-people, and other incidental expenses which would be required before much profit was derived from the farm. From the depressed state of agriculture, the present time is not by any means auspicious for the commencement of business as a dairy-farmer. The requisite dairy utensils will cost about 25l.

*Bement's Improved, Triangular, Expanding Cultivator, or Horse Hoe.* [Communicated for the New-York Farmer, and American Gardener's Magazine.]

The above drawing is taken from one made for Mr. Bement's own use, with only three shares or teeth, and made very light, to be drawn by a small pony. The usual size has three shares and two scarifiers. The shares are double pointed, having one point at the top and another at the bottom, and are attached to the stock by a small screw-bolt and nut in the middle, so that when one point breaks, or is worn out, by turning the other end down, a new point or share is presented. A larger or smaller share may also be attached to the stock as occasion may require. The shares may also be replaced by scarifiers.

By the peculiar construction of the eleva-

the roller or wheel, and with it the beam, can be regulated to any height required; and by raising or towing the hook, the line of draught can be adjusted accordingly. The sides may also be set wider or narrower, to suit any occasion.

In putting in such grains as are proper to be ploughed in, as barley, oats and peas, the larger shares may be used. The shares can be replaced by scarifiers, which are useful for cleaning out quack and other troublesome weeds, as well as scarifying meadows, previous to a top dressing of manure.

This cultivator or horse hoe is, in proportion to its cost, perhaps as valuable an implement as can be had on a farm, serving, as it does, a variety of uses, and being in all cases light and convenient to use; and I should think by the number of orders Mr. B. is receiving, it is coming rapidly as well as deservedly into use.

*Improved Short Horns.* By H. C. [For the New-York Farmer.]

The British Farmer's Magazine, for April, 1835, has been received, but is rather barren of interesting matter. A considerable portion as heretofore is occupied with British statistics and politics, by a writer who seems to be endued with an inexhaustible ductility of writing, and whose speculations, which have no interest here, remind us of the calculations of the extent to which a single grain of gold may be drawn or hammered out, if the means of its extension were equal to its capacity.

This number, however, contains a letter from an American correspondent, whom we are not able to identify, but who shows himself an inquisitive and experimental agriculturist. The subject is the "Acclimation of the Improved Short Horns." As the letter touches on matters of much interest and curiosity, we subjoin it. It is addressed to the Rev. Henry Berry, the editor of the Magazine.

"SIR,—The only apology I can offer for this intrusion on both your time and attention, must rest on the interest and sympathy common to those who are pursuing the same subject with the same views; and when an individual like yourself is so much in advance of his contemporaries, he necessarily becomes subject to the tax of inquiry. Under these impressions have I ventured on a correspondence in which I feel there is but too much of selfishness, though I sometimes indulge the hope that you may possibly feel an interest in the progress of your favorite animals, the improved short horns, in this country, together with the wonderful facility with which they have adapted themselves to a climate whose variations will sometimes range as much as 50° of the thermometer in twenty-four hours; whose winter is rigorously cold and protracted, and whose summers are excessively warm and debilitating; the one sinking the mercury of Fah. thermometer 10° below zero, and the other raising it to 85° and 95° of heat in the shade! Add to this the fact that little or no provision of succulent food, roots, &c. is made for stock in this country, and that they are consequently confined to dry hay for above

seven months in the year, which is generally "fed out" to them on the snow, without even a hovel to stand under by day or by night. To such exposures and hardships was I obliged to submit my cattle, before I could convince the farmers around me that their fine appearance and high condition were not the result of pampering care and attention. Ignorance and prejudice were both arrayed against me, and envy stood close at their heels in case of success.

"I consented to place a very fine young cow on the farm of a neighbor, there to be wintered with his two-year-old stock, and in all respects to fare as they did. She was placed with the young cattle in September, and in October they were driven on to a side hill, with a western aspect, there to winter on the snow, fed with nothing but hay, which was fed out to them twice a day, without house, shed, or barn of any description, to shelter them. The situation was well chosen for the object; it was a cold and bleak exposure, in full view of the village, and at the crossing of two roads which were much travelled. By the 10th of November our winter commenced in earnest; the ground was covered with snow; and remained so until the 19th of March; nor was the cow released from her winter quarters until the 10th of May, when she was turned out to grass in *precisely the same high condition* as when first driven to her winter station. So much for acclimation and fine constitution.

"From my childhood I have been enthusiastically fond of animals, and have communed much with them; from the puerile objects of pigeons and poultry, I passed to the more important stock of a farm, where in turn my hands have been occupied by the unpromising Alderney, the pretty Devon, the imposing Hereford; and at present by the valuable family of improved short horns; which latter have been drawn from the yards of — and —. These are the sources from which I have drawn my present stock, with an occasional cross from the imported bull Admiral, sired by North Star, dam by Comet, which was sent by Sir Isaac Coffin a present to the state of Massachusetts. You will perhaps hardly be prepared for the fact, that the animals derived from —'s stock are decidedly superior to those from —'s — better in constitution, in form, and in their dairy qualities.

"I am, sir, thus particular in my history of these animals, not because they are mine, but because you are well acquainted with the yards from which I drew them; and the knowledge of how they have proved in this country, compared with —'s, may be useful, as all facts are to an inquiring mind. —'s stock have been remarkable for their deep milking—more so, I think, than that of any other in the country.

"I have been much embarrassed by a bull's (from —'s stock) great uncertainty, and I much doubt if he ever sired over a dozen or fifteen calves in a season. A son of his is but one degree better; and so it has been with others of this family after they have become three years old. I think you once owned the dam, Is

there any in-and-in breeding about her, that would account for such inability? My bulls are not kept high; they are put to hay in October, and are kept up until the middle of August, and then run to grass about two months. I do not grain them, or bestow any particular management on them during the season. I should feel greatly indebted to you for any advice you are disposed to give me in relation to this subject; or if willing to give me an account of your own method of raising, feeding, and treating a bull calf, it would be exceedingly valuable to me, and I should consider it a great favor. If attended with less trouble to yourself than a private letter, perhaps you will favor the readers of the British Farmer's Magazine with an article on the subject of the want of vigor so often found in high-bred animals. It would be interesting to trace the course of in-and-in breeding step by step, in its effects on the animal economy. I have sometimes thought that its effects were perceptible on the frame or bone of the animal, then on the muscles, then on the glands, afterwards on the general constitution, and lastly on the very intestines themselves; but with me this is little more than Yankee guessing; with you it is matter of science and experiment. Your several most valuable essays on improving and breeding stock, I have; but I think none of them describe the course of in-and-in breeding. I have myself, with pigs, watched this in-and-in breeding as far as it has been practised, six times between brothers and sisters, and the last produce fatted easiest; this I do not understand.

"Residing as I do in a country scarcely acquainted with the first principles of breeding, and where indeed its science is almost matter of ridicule, I feel at times an anxiety lest I am losing ground; and that some general defect may creep into my herd until it becomes a characteristic feature no longer to be detected by comparison, for such I believe is, frequently the case with those whose opportunity of comparing is, either from circumstances or conceits, confined to their own yards. Of course I can see but very few high bred animals, and my own are seldom seen by any who are competent to criticise the nicer and more finished points of high breeding. You will not therefore wonder at the anxiety and distrust consequent on my insulated situation; and the value I attach to correct portraits of approved animals, which at once address the eye, and leave so much less than the *most able* description could do to the filling up of the imagination. And here, sir, let me acknowledge the great assistance I have received from the excellent portrait of one of your cows, which appeared in the August number of the British Farmer's Magazine, which, while it afforded me a clear comprehension of your beautiful of a short horn, was an admirable illustration of your valuable remarks on compactness of form, and that symmetry of parts which really constitute weight; whereas, it is but too often the case, that the animal of extravagant disproportion in some one or more points, catches the unpractised eye, and captivates the uneducated judgment.

"The best, the most elaborate description of form, is, after all, very unsatisfactory, as it is still to be embodied by the imagination of the reader; and could these creations of the fancy be seen, they would generally be the fac-similes of some favorite figure or style of animal at home. It is, therefore, that I attach so much importance and value to the pencil, as the best possible mode of conveying a correct idea of excellence in form; and feel exceedingly anxious that all the portraits published in that valuable work, the British Farmer's Magazine, should possess the same fidelity and correctness as that which there represents your own cow.

"I have just received, from Mr. J. Ellman's flock, half a dozen most beautiful ewes, and a very fine stout large yearling ram, and judging from this animal I should think he had regained the vigor and constitution which were so deficient in his father's, and that too, he says, without recourse to the "Hampshire cross." I mention this because I remember your five days' visit to Mr. Coke's, where you make allusion to his flock of South-Down breed. I had intended pursuing the same course; but the ram will give the constitution and hardiness necessary for this climate. The ewes are most fashionable and finished specimens of high breeding, and may not perhaps stand our severe seasons. Animals, however, become wonderfully acclimated, and, I am inclined to think, *much hardier*, here, after a few years, than they are when imported. Our horses most certainly endure what would kill an English work-horse. The merino sheep suffered much at first, but our present flocks are as healthy as such formed animals can be. And the short-horns of earliest importation do better than those of more recent arrival—of course I speak of the descendants, and not the animals themselves, though these even become hardier. And with these facts, I have thought that when the blood has been kept pure and the stock not depreciated in this country, that the English breeder might make perhaps an importation or an exchange with this country, that would materially add to the hardihood of his animals. The very suggestion may sound like presumption to an English herder; but I pray you to remember that I have reference *only* to the effect of *climate here* on your *own* excellent materials. For instance, Mr. Ellman has sent what he considers a good selection of animals suitable to breed together. Now, I have no doubt that in three, or rather in five years, I shall have infinitely hardier sheep than any in Mr. Ellman's own flock. And I presume I have better constituted short-horns than those in England; for though I feed no hay *liberally*, with a few raw potatoes to correct the state of the animal's bowels, yet I never pamper or feed high; and though I house them at night, I turn them out all day on the snow, where they run and frolic with the real enjoyment of animal life. Nor are they pinched or drawn up by our cold and severe seasons, but are straight and upheaded.

"Since my arrival of South-Downs, there seems to be a strong desire to import more; and I have suggested to one gentleman,

that he should take his sheep from Mr. Coke's flock, and breed against me; and he so far listens to it as to request I would ascertain the cost of half a dozen yearling ewes, and a buck of his best. Perhaps, should you find time to favor me with a line, you would mention the cost, if you know it.

"Where is Coate's supplement to his Herd Book? I look for it impatiently.

"Very respectfully yours,

"State of New-York, U. S.,  
Nov. 1834."

This letter was a private letter, and as such we forbear any extended comment upon it. Under these circumstances we are at a loss to know on what principle the editor could satisfy himself in giving it to the public; excepting as he may have felt himself at liberty to follow the prevalent fashion; for all honorable confidence seems in a great degree broken up, and private letters and letters of the most confidential character are daily, and without compunction, under a new code of morals, given to the public. This letter, it cannot be denied, is sufficiently fanciful to satisfy the most imaginative.

The wintering of the short-horn cow upon a snow bank, under a bleak and most inclement exposure, and her coming out in the same high condition in which she began the winter, does not appear very decisive for the object for which it is referred to, as it seems the cow, though of foreign stock, was a native of the country, and so from her birth was accustomed to the climate of the country; nor is it without good reason that we wish to be informed whether the other young cattle wintered with her came out in proportionally good condition. If they had not, we think the fact would have been stated.

The want of vigor, or power of procreation, in the high bred bulls, is a well understood fact; and a pretty serious inconvenience, as some of us have found to our cost. That this defect is to be attributed to the system of breeding in-and-in is not so well established, though we are not disposed to controvert it; but the "yankee guessing," by which this writer, who certainly is an intelligent man, proposes to trace the effects of this system of breeding in-and-in upon the animal economy, and concludes that "its first effects were perceptible on the frame or bone of the animal, then on the muscles, then on the glands, afterwards on the general constitution, and lastly on the very intestines themselves," can scarcely be considered as any thing else, we design no offence, than pure moonshine.

The assertion "that —'s stock have been remarkable for their deep milking, more so, I think, than that of any other in the country," is a bold assertion, and one to which we at once demur. It is too late in the day to establish this point by a simple declaration,—we ask for, we demand, the proof; and if gentlemen expect to be believed, they will be prompt to give it. Not long since I respectfully requested of the liberal and munificent proprietors of the

improved short horns in this country, to give us some exact and authenticated statements of the produce of their fine cows in milk and butter and cheese. Why do they not do it? It is a matter of easy ascertainment, and the result is of great public importance. I took occasion at that time to give a list of native cows, most of which had come under my own observation, with detailed and fully certified statements of their product. Let the champions and owners of the improved short horns show one like it *if they can*. I for one shall be glad to see it. I have no prejudice against this stock; my prejudices have all been the other way; but I confess myself entirely skeptical as to their value for the dairy. I have some facts in this matter which I shall give to the public, when I think there is occasion. I can only say, that I have had seven of the are made. If this article should attract the attention of a very intelligent writer for the Genesee Farmer, who, under the signature of *Ulmus*, often gratifies and instructs the readers of that admirably conducted periodical, we wish he would by actual facts within his own knowledge vindicate the claims of a race of animals of which he comes forward as so ardent a champion. We know he is well read on this subject, but we want facts under his own accurate personal observation.

That the estimation of the short horns as a dairy stock has very much depreciated in England, seems hardly to be doubted. There is in this very number a notice of Shirreff's "Tour through North America" for agricultural information. Shirreff is spoken of by the editor as "his talcows; and there is not a single property in relation to thrift or dairy produce, in which they have been superior, or indeed equal, to other stock in my yard. In respect both to quantity and quality of milk, they have been quite inferior. I have no question that there are very superior individuals among them; but I believe none that have surpassed some of the instances which I gave. As a race, are they superior for the dairy? We will not say we doubt it, but we question it; and we question it in no improper spirit, but solely with a view to ascertain the truth, and that the agricultural public may know how far they may rely upon the representations which entered correspondent." He says further of him, that "Mr. S. is a farmer of the first rank, a natural philosopher, a statistician, politician, and a citizen of the world. Few persons could be better fitted for the task of giving a view of the infant agriculture of America." Yet Mr. Shirreff, in describing the live stock of a farm he visited, says, "There was a fine short horn bull intended to improve the dairy stock, which I did not see. This contemplated improvement originated from perusing the writings of the Rev. Henry Berry of England. I took the liberty of advising the cross to be tried on a small scale, believing the short horns the worst milking breed in Britain."

We are often entertained with the account of Mr. Charles Colling's sale of short horns in 1810; and of the magnificent sale of the famous bull Comet, for one

thousand guineas. Why do not gentlemen report some later sales? In the absence of this information I shall take the liberty of giving two accounts of recent date.

"At the Rev. Henry Berry's fourth sale of improved short horns, on the 11th February, 1834, the following prices were obtained:

Lot 1, 2 years old, -	£24 3 0
2, do. - - - - -	36 15 0
3, do. bought in, £45 bid.	
4, 3 years, do. do.	
5, 3 years, - - - - -	29 18 0
6, calf sold with the above.	
7, 3 years, - - - - -	30 9 0
8, 3 years, - - - - -	38 17 0
9, 8 years, - - - - -	33 12 0
10, 9 years, - - - - -	26 5 0
11, heifer calf, - - - -	15 15 0
12, 10 years, - - - - -	36 15 0
13, 10 years, - - - - -	48 6 0
14, 2 years old bull, - -	39 18 0
15, 1 year old do., - - -	45 3 0
16, bull calf, - - - - -	15 15 0
17, do. - - - - -	31 10 0
18, do. nine weeks old,	32 11 0

These prices among us of course would be deemed extravagant, but they are evidently below what was expected, from some of the stock having been bought in; and they bear a very small comparison to the prices in Colling's sale.

The present number of the British Farmer's Magazine contains an account of a sale of improved short horns, made on 25th of February, 1835, and the two following days. We quote the sales of the cows and of the bulls.

#### cows.

Rosette, 9 years old,	21	guineas.

Falstaff, - - - - -	18	"
Tommy, - - - - -	30	"
Plenipo, - - - - -	26	"

This sale shows, we think, pretty clear.

ly, a depreciation in the value of this stock, though prices may have been materially affected by local or temporary circumstances, with which we are not acquainted.

The value of the improved stock for beef is a subject upon which I shall not now enter. Two pairs of very superior cattle of this stock were last spring sold in New-York market, which were raised and fattened in Albany. One of the oxen was a very uncommon animal. At some future time perhaps we shall notice this subject more particularly; but we regret to state, which we do upon competent authority, that the reported enormous weight of these cattle was a gross exaggeration. It is said that some English gentlemen, who saw these fine cattle, condescended to say that they had seldom seen much finer cattle than these at Smithfield; and they thought, if we continued to progress as we had done, we should presently in the character of our beef equal their markets. This was John Bullism "up to the hub." We will take the reports of the Smithfield market; and we have no hesitation in saying that the average quality of the beef cattle sent year by year to Brighton market is quite equal to that of Smithfield, or any other part of the world; and though not so familiar with them, we have no doubt that the cattle of New-York and Philadelphia are fully equal to those of Brighton. Besides most of our stall-fed cattle, at least in the Connecticut valley, are fattened upon Indian meal and the very best of hay. Most of the English beef is made of straw and turnips; which can never produce so fine beef as the feed which we are accustomed to give them. H. C.

Meadowbanks, July 10, 1835.

NEW-YORK AMERICAN.

AUGUST 1-7, 1835

LITERARY NOTICES.

ELIA, by CHAS. LAMB. N. Y., GEO. DEARBORN. The four numbers of the *Republic of Letters*, containing these charming essays of Chas. Lamb, have been formed into a separate pamphlet, of some 125 pp., which is presented at the extraordinary price of 25 cents. When the neatness and distinctness of the typography is considered, the capital white paper, and the amount of matter, this is indeed an extraordinary price. We need not add, that a more agreeable or a more unexceptionable collection, than this, cannot, at this locomotive period of the year, be packed away for hourly use, in one's travelling sack.

HISTORY OF THE LIFE AND VOYAGES OF CHRISTOPHER COLUMBUS AND OF THE VOYAGES AND DISCOVERIES OF THE COMPANIONS OF COLUMBUS. By WASHINGTON IRVING. 3 vols. 8vo. Philadelphia, Carey, Lea & Blanchard.—We have here a new and handsome edition of this great American work; which will live, while the language in which it is written, and the continent revealed by its Hero, last.

The Life of Columbus has undergone, as we learn from the publishers, a complete revision by the author, and new matter has been added to the appendix.

Vol. 3 presents, in a uniform style with that of the other two volumes, the Lives and Voyages of Columbus's Companions, and together they constitute a mass of historical information and documents,

prepared and arranged by one of our own countrymen, which all reading Americans should possess. We extract from the Appendix in Vol. II., the last note—referring to the signature of Columbus—of which the details, will be new probably, and interesting, to most of our readers:

As every thing respecting Columbus is full of interest, his signature has been a matter of some discussion. It partook of the pedantic and bigoted character of the age, and perhaps of the peculiar character of the man, who, considering himself mysteriously elected and set apart from among men for certain great purposes, adopted a correspondent formality and solemnity in all his concerns. His signature was as follows:

S.  
S. A. S.  
X. M. Y.  
XPO FERENS.

The first half of the signature, XPO, (for CHRISTO,) is in Greek letters; the second, FERENS, is in Latin. Such was the usage of those days; and even at present both Greek and Roman letters are used in signatures and inscriptions in Spain.

The ciphers or initials above the signature are supposed to represent a pious ejaculation. To read them one must begin with the lower letters and connect them with those above. Signor Gio. Batista Spotorno conjectures them to mean either Christus (Christus) Sancta Maria Yosephus, or Salve me, Christus, Maria, Yosephus. The North American Review, for April, 1827, suggests the substitution of Jesus for Yosephus, but the suggestion of Spotorno is most probably correct, as a common Spanish ejaculation is "Jesus Maria y José."

It was an ancient usage in Spain, and it has not entirely gone by, to accompany the signature with some words of religious purport. One object of this practice was to show the writer to be a Christian. This was of some importance in a country in which Jews and Mahometans were proscribed and persecuted.

Don Fernando, son to Columbus, says that his father, when he took his pen in hand, usually commenced by writing "Jesus cum Maria sit nobis in via;" and the book which the admiral prepared and sent to the sovereigns, containing the prophecies which he considered as referring to his discoveries, and to the rescue of the holy sepulchre, begins with the same words. The practice is akin to that of placing the initials of pious words above his signature, and gives great probability to the mode in which they have been deciphered.

FRANCESCA CARRARA, by the the author of Romance and Reality, &c. 3 vols. Philadelphia, E. L. CAREY and A. HART.—An Italian love story, carried through three volumes and two brilliant courts, that of Louis XIV. and that of the restored Charles—during the course of which, figure the historical personages who make up the ordinary *dramatis personæ* of the tales of that period—is here presented to us by L. E. L. It is hard reading—and we frankly admit that we have not mastered it.

DACRE, a novel—EDITED BY THE COUNTESS OF MORLEY. 2 vols. Philadelphia, CAREY, LEA & BLANCHARD.—This is a novel of our day and generation, though not of our country. It is agreeable, sprightly, and as to the chief characters, *Dacre* and *Lady Emily*, well conceived and sustained.

It is some time since this novel appeared, and was well received in London—and we are surprised, as times and tastes go, that it was not republished here before.

FOUR YEARS' RESIDENCE IN GREAT BRITAIN, from 1831 to 1835, by C. COLTON. N. Y., HARPER & BROTHERS. We are not destined to fame, we fear, as tourists in foreign lands. These volumes from the pen of a clerical gentleman—attached we believe to the naval service—differ indeed essentially from those of a brother chaplain, Mr. Stewart, by not recording or seeking to record, in "rose colored" phrase, the experiences of the writer in high society, but they are liable to the

same objection, of want of originality and vigor. The style of Mr. Colton is negligent, and—the he speaks of being embarrassed by the copiousness of his materials, so much so that we are to have another work from him, under the title of *London*, descriptive of that great metropolis—there is in his pages a most undue quantity of extracts from guide books, newspapers, and legends of childhood—the story of Prince *Levellynn* and his dog *Gelert* for instance.

That portion of the second volume which treats of the Established Church of England, seems to us, objectionable in spirit, and exceedingly partial in its selection of facts. It is, indeed, little more than a recapitulation of the partizan charges, in their most exaggerated form, used by political or personal opponents—fortified by a copious selection from the Irish press of the enormities—not softened in the relation—to which the exaction of tithes too frequently leads in that ill-governed country—and without any glimpse of the other side of the question. Such a mode of treating such a subject, does not appear to us either just, philosophic, or christian.

A good book of travels in England, by an American, is yet to be written—for the capital volumes of *Simond* hardly belong to us, though the writer was an adopted citizen.

ORATION DELIVERED ON THE 4TH JULY, 1835, BEFORE THE CITIZENS OF BEVERLY, WITHOUT DISTINCTION OF PARTY, by EDWARD EVERETT,—published by request; Boston, RUSSELL OGDEN & Co.—The character of Washington is, after an eloquent exordium and introduction, made the topic of this July oration. A happier one, as in such natural association with the day, and so susceptible of brilliant illustration, could not have been selected,—and justice has been done to it.—We can only find room, however, for a comparatively brief extract. After describing the conduct of Washington on the fatal field of *Braddock's* defeat, his daring efforts, his conspicuous figure, his miraculous escapes, the orator proceeds:

From this period, the relation of Washington to his country was sealed. It is evident that his character, and conduct, and preservation,—though he was scarcely twenty-three years of age,—had arrested the public attention, and awakened thoughtful anticipations of his career. I confess there is something, which I am unable to fathom, in the hold which he seems already to have gained over the minds and imaginations of men. Never did victorious Consul return to republican Rome, loaded with the spoils of conquered provinces,—with captive thousands at his chariot wheels, an object of greater confidence and respect,—than Washington, at the close of two disastrous campaigns, from one of which he was able to save his regiment, only by a painful capitulation,—in the other, barely escaping with his life and the wrecks of his army. He had formed to himself, on fields of defeat and disaster, a reputation for consummate bravery, conduct, and patriotism. A sermon was preached to the volunteers of Hanover County, in Virginia, by the Rev. Samuel Davis, afterwards President of the Princeton College, in which he uses this memorable language: "As a remarkable instance of patriotism, I may point out to the public that heroic youth, Colonel Washington, to whom I cannot but hope Providence has hitherto preserved, in a signal a manner, for some important service to his country."

The entire completion of this extraordinary prediction was of course reserved for a future day, but from the moment of its utterance its fulfilment began. Terror and havoc followed at the heels of *Braddock's* defeat. The frontier settlements were broken up,—the log-cabins were burned,—their inmates massacred, or driven in dismay across the mountains.—A considerable force was raised in Virginia, and Washington was appointed its Commander-in-chief. But the councils of England were weak and irresolute, and no efficient general head as yet controlled those of the colonies. The day star of Pitt was near, but had not

yet ascended above the horizon. Disaster followed disaster, on the frontiers of Virginia, and Washington, for two years and a half, was placed in precisely the position, which he was afterwards to fill in the revolutionary war. A reluctant and undisciplined militia was to be kept embodied by personal influence; without pay without clothes, without arms. Sent to defend an extensive mountain frontier with forces wholly inadequate to the object,—the sport of contradictory orders from a civil governor inexperienced in war,—defrauded by contractors,—tormented with arrogant pretensions of subaltern officers in the royal army,—weakened by wholesale desertions in the hour of danger,—maligned,—the youthful Commander-in-chief was obliged to foresee every thing,—to create every thing,—to endure every thing,—to effect every thing, without encouragement, without means, without co-operation. His correspondence during the years 1756, and 1757 is, with due allowance for the difference of the field of operations, the precise counterpart of that of the revolutionary war, twenty years later.—You see it all,—you see the whole man,—in a letter to Governor Dinwiddie of 22d April, 1759:—

"Your honor may see to what unhappy straits the inhabitants and myself are reduced. I am too little acquainted, sir, with pathetic language, to attempt a description of the people's distresses, tho' I have a generous soul, sensible of wrongs and swelling for redress. But what can I do? I see their situation, know their danger, and participate their sufferings, without having it in my power to give them farther relief, than uncertain promises. In short, I see inevitable destruction, in so clear a light, that unless vigorous measures are taken by the assembly, and speedy assistance sent from below, the poor inhabitants that are now in forts must unavoidably fall, while the remainder are dying before a barbarous foe. In fine, the melancholy situation of the people,—the little prospect of assistance,—the gross and scandalous abuse cast upon the officers in general,—which is reflecting on me in particular for suffering misconduct of such extraordinary kinds,—and the distant prospect, if any, of gaining honor or reputation in the service, cause me to lament the hour, that gave me a commission, and would induce me, at any other time than this of imminent danger, to resign without one hesitating moment, a command from which I never expect to reap either honor or benefit; but on the contrary, have an almost absolute certainty of incurring displeasure below, while the murder of helpless families may be laid to my account here! The supplicating tears of the women, the moving petitions of the men melt me into such deadly sorrow, that I solemnly declare, if I know my own mind, I could offer myself a willing sacrifice to the butchering enemy, provided that would contribute to the people's ease!"

And here I close the detail. You behold in this one extract your Washington, complete, mature, ready for the salvation of his country. The occasion, that calls him out may come soon or it may come late, or it may come both soon and late;—whenever it comes, he is ready for the work. A misguided ministry may accelerate or measures of conciliation retard the struggle; but its hero is prepared. His bow of might is strung and his quiver hangs from his shoulders, stored with three-bolted thunders. The summons to the mighty conflict may come the next year—the next day; it will find the rose of youth on his cheek, but it will find him wise, cautious, prudent, and grave: it may come after the lapse of time, and find his noble countenance marked with the lines of manhood, but it will find him alert, vigorous, unexhausted.—It may reach him the next day on the frontiers in arms for the protection of the settlement; it may reach him at the meridian of life, in the retirement of Mount Vernon; it may reach him as he draws near to the grave; but it will never take him by surprise. It may summon him to the first Congress at Philadelphia; it will find him brief of speech, in matter weighty, pertinent, and full, in resolution firm as the perpetual hills, in personal influence absolute. It may call him to the command of armies; the generous rashness of youth alone will be chastened by the responsibility of his great trust, but in all else he shall exhibit unchanged that serene and godlike courage, with which he rode unharmed through the iron sleet of Braddock's field. It may call him to take part in the convention, assembled to give a constitution to the rescued and distracted country. The soldier has dis-

appeared, the statesman, the patriot is at his post of duty; he sits down in the humblest seat of the civilian, till in the assembly of all that is wisest in the land, he by one accord is felt the presiding mind. It will call him to the highest trust of the new formed government; he will conciliate the affections of the country in the dubious trial of the constitution; he will organize, administer, and lay down the arduous duties of a chief magistracy unparalleled in its character, without even the suspicion of swerving in a single instance from the plan of rectitude. Lastly the voice of a beloved country may call him for a third time, on the verge of three score years and ten, to the field. The often sacrificed desire for repose,—the number and variety of services already performed;—his declining years might seem to exempt him, but he will obey the sacred call of his country in his age, as he obeyed it in his youth. He gave to his fellow citizens the morning, he will give them the evening of his existence;—he will exhaust the last hour of his being, and breathe his dying breath, in the service of his country.

A DISCOURSE ON NATURAL THEOLOGY, showing the nature of the Evidence and the advantages of the Study, by HENRY LORD BROUGHAM, F. R. S., and Member of the National Institute of France. 1 vol. Philadelphia, CAREY, LEA & BLANCHARD. —The extraordinary man who is the author of this treatise, seems to have a capacity for work, and a reach of subjects, beyond any living person. This discourse, as we learn from a prefatory address to his friend Lord Spencer, (late Lord Althorp,) was chiefly written in 1830 and 1831, in the midst of an active professional and political life. Some additions were made in 1833, and others in 1834, while Lord Chancellor—and the whole has been revised since his retirement from that high station.

A more remarkable contribution to the cause of sound and just thinking on natural Religion, considering the ordinary pursuits and subjects of the investigation of the author, has never, probably been made public—and they who may dislike Lord Brougham as a politician, or distrust him as a philosopher, will find it difficult to resist his power as a theologian, deriving his arguments in favor of the existence of a Deity, even more from the intellectual qualities of man, than from the physical structure of the universe. And herein consists one of the chief novelties of this work, that it argues from the mind itself, to the existence of the great first cause.

THE AMERICAN MONTHLY MAGAZINE—for August—D. K. MINOR & T. & C. WOOD.—Punctual to the hour, this periodical, for August, is just laid upon our table. We had only time to glance our eye over the capital *Five Island Ana*.

#### EUROPEAN INTELLIGENCE.

LATER FROM EUROPE.—By the *Troy*, from Liverpool, papers of 1st July from London are received.

The intelligence of greatest interest by this arrival is that of the death of the Carlist chief, Zumalacarrégu, which—such is the interest always inspired by heroism, and the development of great resource and ability in adverse circumstances—we confess we heard with regret, though we desire the success of the young Queen's cause, and abhor the cruelties which Zumalacarrégu too often practised.

From an article in the *Journal des Debats*, on the intervention in Spanish affairs, it would seem that a more national character is to be given to the efforts both of England and France, by the expedition to the coast of Spain of vessels of war of both nations, and by France, of the foreign legion in mass, and under French officers, now serving in Algiers. On the other hand, it would seem, that

the Northern powers disapprove this intervention and if, as has before been said, enlistments and money for Don Carlos should be furnished by those Powers, the chief nations of Europe would find themselves in presence and in hostile array on the soil of Spain—and a fierce contest, wholly foreign to the original cause in which they embarked, would probably soon embroil the whole Continent.

Another change has been made in the command of the Queen's troops. Valdez, the late Minister of War, who quitted his seat in the cabinet to take command of the army, having been recalled. The death of the great Carlist partizan, however, is more likely to serve the Queen's cause, than the efficiency of her own commander.

Matthews, the comedian, is dead.

Lord Durham has been appointed British Minister to the Court of St. Petersburg.

Deutz, the Jew, who betrayed the Duchess de Berry into the hands of the French Government, has published a pamphlet detailing an account of his treachery on this memorable occasion.

Baron Gras, the celebrated historical painter, whose pencil adorned the cupola of the Pantheon, committed suicide on Friday last. His body was found in the Seine on Saturday. He had left a letter in his writing desk announcing his intention; and had sent his last will for safe custody to his attorney.

The Emperor of Austria has invited the northern Sovereigns to a conference at Toplitz, and they have accepted the invitation. The meeting will take place in the latter end of October. Preparations are made with the greatest activity for the review at Kalisch; the Russian troops are expected at Dantzic on the 1st and the 4th of August; and the Emperor and the Empress will arrive on the 16th.

According to the last accounts from Naples, Vesuvius continues to throw out stones and cinders; and a grand eruption is expected. Some slight shocks of an earthquake have lately been felt in the south of Italy.

THE LADIES.—Mr. Grantly Berkeley gave notice, on Thursday night, in the House of Commons, (for July 16th,) of a motion for a select committee to consider the best means of setting apart and adapting a portion of the strangers' gallery for the admission of ladies during the debates.

EMIGRATION.—The total number of emigrants from the United Kingdom in the last year, was 76,222, being an increase of 13,695 on the number of the former year. Of these, 32,799 sailed from Ireland. The Irish emigrants of the last year exceeded those of the former by 10,604.

Mehemet Ali has withdrawn his opposition to the expedition of Colonel Chesney on the Euphrates, which arose solely from his not having received instructions from the Porte. The Malta Gazette contains an account of the disembarkation of the expedition at the mouth of the Orontes. Hassan Pasha Begter, Bey of Tunis, died on the 20th of last month, and is succeeded by his brother, Sidli Mustapha. It is supposed that Turkey, or to speak more truly, Russia, will deal with Tunis as with Tripoli.

Zumalacarrégu is dead.

This is the most important intelligence that has been communicated from Spain since the commencement of the civil war. In him was concentrated the hope of the Carlists, and with him sinks the cause of which he was the chosen champion. The death of Zumalacarrégu was communicated to the French government by telegraph. The fact was thus officially announced on the Paris Bourse on the afternoon of Saturday:

"TELEGRAPHIC DESPATCH.

"BAYONNE, 27th June.

"General Harispe to the Minister at War and the Minister of the Interior.—Zumalacarrégu died on the 25th inst., at 11 o'clock, in the morning, in consequence of his wound.

"DE RICHELIEUX."

Zumalacarrégu was personally one of the bravest officers in Spain, but like most of his chivalrous countrymen, his valor was stained by an innate love of cruelty, which he too often indulged at the expense of the lives of the unfortunate prisoners who fell into his hands. His talents were altogether military; nor had he the remotest idea of the pop-

sibility of governing men by any other means than the influence of well grounded fear. As a soldier, he was a strict observer of discipline, and exacted from those under him a blind obedience to his commands. It is asserted, however, that notwithstanding the cruelty of his disposition, he refused to carry the war beyond the banks of the Ebro, and that his real object was to secure the franchises of the Basque provinces by separating them from the rest of the kingdom of Spain, and elevating them into an independent State, of which Don Carlos was to be proclaimed King. On the other hand, it has been maintained that Zumalacaregui prevented Don Carlos from capitulating, and almost kept him prisoner, from an apprehension that he himself would be sacrificed to gratify the vengeance of the Queen Regent and her government.

Letters from Madrid to the 21st inst. announcing the recall of General Valdez from the command of the army in the North, have been received. The late Captain General is succeeded in the command by General Murillo, assisted by General Sarco del Valle, who has been appointed chief of the Staff, and is now on his way to Pampeluna, the head quarters of the Constitutional army. No cause is assigned for the removal of Valdez, but we have reason to know that his want of energy greatly dissatisfied the Queen's Government.

Madrid was tranquil up to the date of the letters just received. The discovery of the Carlist conspiracy in the capital a few days before, was really fortunate, as its ramifications had been extended in several dangerous directions. The ringleaders of the plot have been secured.

By command of the Spanish Government, his Britannic Majesty's Order in Council of the 10th of June, suspending the Foreign Enlistment Act, has been posted up on the Madrid Bourse.

The French Journals of Saturday bring a report of the death of General Erasó, Zumalacaregui's successor in the command of the Carlists, who is stated to have been killed by a fall from his horse. Erasó was a man of courage, but his flight from France, where he was a prisoner on parole, reflects a deep stain on his character both as a soldier and a man of honor. We regard the rumor of his sudden death as premature, although repeated in several letters dated from the Spanish frontiers.

*Correspondence of the London Morning Herald.*

ATHENS, May 31.—The 4th of May was hailed by the Greeks as a national fête; the bones of Karaiskaki were brought from Salamis, and landed at the Piræus under a salute of minute guns, from whence conducted to the spot in the rear of the Phalernon, where it is thought he fell. A very neat monument had been erected (about 300 paces from the new roads), alongside of which the King, accompanied by the whole Corps Diplomatique, and a very numerous staff, received the procession; the funeral oration was read by M. Rizos, the Minister for Foreign Affairs, and his Majesty was addressed by one of the old Capitani, recalling to mind Karaiskaki's last words. His Majesty most graciously took off the Grand Cordon of the Saviour, which he wore himself, and placed it on the remains, regretting that he had not had the opportunity of paying the honor to him while alive which he had paid to his remains, and ordered that this cross should remain to the family as a memorial of their ancestor's virtues: this highly delighted the Greeks, who enthusiastically rent the air with "Long live King Otho." The daughters have received a portion of land and 6,000 drachms as a dowry.

A number of the Capitani and old Philhellenes of those present in the different battles about Athens gave, a few days ago, a Palicari dinner in the Olive-grove to the King, and as divers rumors were afloat as to who should remain with the King, they studiously avoided inviting General Heideck, but on their return in the evening they assembled before Count Armanberg's door, sung national airs, and cried out, "Long live the King," "Long live Armanberg." This was a pretty good hint of the wish of the nation, as they were most of them leading men, and men of all parties. It is said M. Kleutze, the Architect, is preparing at Munich a machine, with which he is to return here to raise the fallen columns of the Parthenon; the Government had just laid a tax on those who visit the Acropolis, by way of making them contribute to its repairs.

Sir Josias Rowley is still at Salamis, with the squadron, but it is rumored on the arrival of the packet they will sail for the East.

Every vessel that comes from the Black Sea men-

tions that great preparations are making at Sebastopol, said to be for a summer cruise.

M. de Jenison arrived a few days ago to compliment the King on his coming to the throne on the part of the King of Bavaria; it is said he goes from this Bavarian Ambassador to Paris.

Captain Sir Edward Lyons arrived here three days ago in 11 days from London; his arrival has excited considerable interest here; his being so generally liked in Greece has made every one believe that he has brought some good news, but as yet we only know he was bearer of despatches.

The Greeks, who are naturally such a lively set and fond of news, have been greatly disappointed that their young King should be so diletant in deciding; it has but just been settled, at the last moment, that Count Armanberg should remain, but we know not in what capacity. This has been a busy week. The Demarchos has at last been named. Streets have been opened for the procession of the King's going to Church, and the programme of the ceremony that is about to take place has just been made public. This evening at sunset 26 guns will be fired, and 75 to-morrow at daylight. At 8 o'clock, A.M., the troops will line the different streets. At half past 9 o'clock, the Greek functionaries, headed by the Ministers, repair to the palace, when the King, seated on the throne, will receive the Regency. Count Armanberg will deliver a speech suitable to the occasion. The Regency is then to declare that it deposes its power into the hands of His Majesty. The Minister of the King's household takes charge of this declaration. His Majesty then retires to his private apartments; a herald is to proclaim the accession of His Majesty to the people, and couriers sent off to all the departments and provinces. At half past 10, His Majesty, accompanied by the Ex Regency and Greek Ministers, &c. proceeds to the church prepared for the occasion, where he will be received by the corps diplomatique, and the admirals and captains of the vessels anchored at Salamis and in the Piræus. During the Te Deum a salute of 101 guns is to be fired, after which the King returns to the palace in the same order, when he will receive the felicitations of the corps diplomatique, the Greek Ministers, other functionaries, &c. At sunset another salute of 101 guns will be fired; the town is ordered to be illuminated in the evening. We are to have reviews, and during the three days an imitation of the Olympic games. We are in expectation of a change of Ministry, a long list of promotions, &c., nothing yet having transpired.

The coronation is put off until the King's marriage, partly for want of a crown and sceptre, those ordered in Paris not having arrived in time, and partly on account of the expense.

ACCESSION OF PRINCE OTHO.

*Otho, by the Grace of God King of Greece, to the Greeks:*

Greeks,—When by the confidence of the high mediators of your independence, and by your free choice, I was called to the throne of Greece, I abandoned my parents and my country, I left all that I had dear to me, and, impelled by the desire to fulfil my duties, I hastened in the midst of you to consecrate to you my endeavors, my cares, and my entire love. You have welcomed me with joy, with mutual love. You have answered my love to you! I called on you to be united; you all obeyed my call. Anarchy was overwhelmed. The unpardonable works of a few individuals ceased, without leaving a shadow behind, and tranquillity and order reigned throughout our beautiful land. Your families, your properties, found the protection of which for a long period of time they had been deprived.

Under the shadow of the throne, the culture of your lands flourished, your habitations rose from their ruins. The communes were drawn closer together, tribunals were organized, the foundations of many benefits laid, many wounds were cicatrized. Thanks to the Divine Providence that watches over you! Thanks to the Great Powers who have continued their favor and their succor to you! Thanks to your noble sentiments, by which the institutions of the Government were received with confidence and devotion!

Greeks, notwithstanding all the bounties which the favor of the Omnipotent has showered on Greece, there exists yet many wounds still bleeding from the events of past years. Notwithstanding all the progress which the country has made, it has yet need of innumerable ameliorations, of great care, and of serious attention, before the traces of

the many sufferings which for numerous centuries have overwhelmed with unexampled destruction the fine soil of Greece, can disappear.

Greeks, I know your sufferings, your wants, your wishes. I know the unexampled sacrifices that you have made for your country, your magnanimity, the heroic bravery with which you have fought, the glory of your immortal ancestors, your own renown. I know the full extent of your just hopes of a more glorious and happy future.

Greeks I will remain firm amongst you. My regard shall be continually towards you—towards your good—towards your happiness. No labor shall weary me, no difficulty shall discourage me—I shall live among you, and for you. This day, the period at which I fully assume the reins of government—I again promise you to protect the holy religion of my subjects, and to be the sure support of their holy church—to grant justice to all—to be faithful to the laws—to protect with the divine assistance, your liberties, your rights, and your independence, from all attacks—and, in the whole of my administration, to have before my eyes your happiness and your glory.

With unchangeable firmness, I will preserve order and public tranquillity, for without these security cannot exist.

My Royal grace shall be granted to all those unfortunates who, by sentences of the tribunals, are at this time deprived of their liberty. But the rigor of the laws shall be put in force against those who in future shall dare to compromise the tranquillity of the country; the security of the kingdom demands this.

Far from you be all passions, all discord, and every unworthy action; be united forever.

I will take good care for the performance and perfection of the laws, and with all my power protect your property, your legitimate liberties, and endeavor to consolidate them gradually by institutions and laws adapted to the state of the country, and to the just wishes of the nation.

On every occasion I will evince my profound veneration for the Eastern Church; and on this point, in respect to the throne of Greece, as far as regards my posterity, I will take particular care and consideration.

I will devote my attention to the schools, and take especial care for their increase and amelioration. To the arts and sciences I will give every succor of which they can have need, that they may again revive in Greece, their ancient country and glory.

I will endeavor in every way to augment the happiness of the country, to encourage industry and commerce, to supply the defects of the Administration; especially will I take the greatest care for the improvement of the public resources, and with unwearied study endeavor, as soon as possible, to create an equilibrium between the revenue and the expenditure.

I will always have before my eyes the sacrifices that every one has made for his country, but the extent of my consideration must be limited by the means which exist.

Greeks my trust is in you—my love to you has no bounds. In your affections, in your confidence, I find the greatest gratification.

The task of government is heavy—I feel it and you must not be animated with unreasonable hopes. Gradually, and little by little, it is only possible to arrive at the goal of your wishes, which are also mine. With courage I assume the duties which the hand of the Omnipotent has imposed upon me, by the Divine grace, and your aid, I will fulfil them.

Your glory, your happiness, are my only objects. To succeed in these will be my greatest reward.

ATHENS, 20th May, [1st June,] 1935.

SUMMARY.

The U. S. Frigate *Constitution* is, according to the Gazette, under sailing orders for the Mediterranean.

OSWEGO LOTS.—A lot in East Oswego, of 60 ft et front by 120 feet deep, was sold last week for \$25,000.

A new line of PACKET BOATS on the Canal from Utica to Oswego, now carries passengers and finds them for Fifty Cents.

BALLSTON SPA.—We have been requested by a

gentleman just returned from the Springs, to state that the house at *Baltston* is in fine order for the reception of company, and that every effort is used by its present proprietor, *Mr. Watrous*, to accommodate visitors.

To families and invalids wishing to spend a few weeks pleasantly in the country, few establishments, he says, offer greater attractions than *Sans Souci*.

FROM THE ROCKY MOUNTAINS.—*St. Louis, July 19, 1835*.—*Mr. Campbell*, of the firm of *Sublette*, and *Campbell*, reached this city on Wednesday last, from the Rocky Mountains. This gentleman left here on the 9th of April last, by land, with but two companions, to perform a journey of one thousand miles, through a desert land, untenanted save by savages. He returned on the 15th of July. If we deduct several days, during which time he was detained in the settlements, it will leave only three months for the accomplishment of this perilous adventure. The same route was never before travelled in so short a period. By the way, we shall think nothing of making excursions to the Mountains; and undertake them with scarcely greater inducements than govern the multitudes who flock to our places of fashionable resort in the summer months.

*Mr. Campbell* was not molested in any manner, by the numerous bands of Indians through whose country he was compelled to pass. He remained about fifteen days at the company's post at the foot of the Black Hills. Returning, he resolved to attempt the navigation of the Platte river, a means of transportation which has heretofore been, by the traders generally, deemed altogether impracticable. He accordingly constructed a *batteaux*, loaded it with a large number of packs of Buffalo robes, and by the occasional employment of small boats made of skins, he was enabled to descend the river a distance of six hundred miles in safety. The navigation of the Platte is made very difficult by its great width, its shallowness, the absence of a channel in any part of it, and its quick-sand bottom.

The traders and trappers in that country during the past winter, were generally successful. *Mr. Campbell* understood from some of the Snake Indians, and little doubt is entertained of its correctness, that a party of Indians of an adjoining tribe had murdered two of the trappers belonging to the New England expedition under *Capt. Wyeth*.—This is the only outrage known to have been committed during the year, in that country, upon Americans.

The U. S. Dragoons under *Col. Dodge*, were at the Grand Pawnee Village. They were in excellent health—had formed a very advantageous treaty with the Pawnees, and were shortly to proceed to the *Aurickaree* village, a nation particularly hostile to our people, for the purpose of holding a council with them. This tribe, to the number of a thousand warriors and about 4000 lodges, were four days travel from *Col. Dodge's* encampment. *Mr. Campbell* had an interview with them at their village—was hospitably treated, and informed by them of the position of the Dragoons, and of the expected visit. Preparations were being made to give them a favorable reception.—[Republican.]

[From the Illinois Register.]

FROM THE DRAGONS.—We have been politely furnished by *O. H. Browning, Esq.* with the following interesting extract of a letter addressed to him from *Cantonment Leavenworth*, by a gentleman who accompanied the U. S. Dragoons, in the summer of 1834, in their expedition to the Pawnee villages. The extract contains some new and entertaining historical facts, as also a graphic description of the scenery presented at the Pawnee Peaks; and we doubt not will be perused with interest by our readers.

"On the 19th of July we again resumed our march under the guidance of the above-named Pawnee Mohaw, who, to my mind, proved himself to be a treacherous villain; for he led us a circuitous route of three days, over an excessively rugged rocky country, and amid inconveniences of every description, when, on our return to the encampment, we traversed a beautiful prairie, and the distance not to exceed forty-five miles. Yet I, for one, did no regret it, for our way led through scenery not exceeded—I hardly believe equalled. I have read of the Alps, and have seen paintings of the most celebrated portion of Alpine scenery.—The Alps are higher; but in sublimity, grandeur,

and general effect, they must, and in time will, yield the palm to the hitherto unknown, unvisited Pawnee Peaks. Here the gradual swell, the beetling precipice, the castellated battlement, the solitary tower, the glittering, roaring cascade, the shady vale, and opening vista, disclosing in its turn distant views of new grandeur—all, all the rich combinations of mountain scenery are here thrown together, forming an unrivalled whole, which, in years to come, will be the goal of all travellers on earth.

"On the evening of the 21st we reached the goal of our enterprise, the long-sought Pawnee village. Here was new matter of wonder. We approached a sweep of perpendicular mountains, whose tops are wholly inaccessible to the human foot from this side, and reached the village through the passage which leads to it, a narrow defile, which one hundred good men, with a proper armament, and a good engineer, could keep against the countless legions that Napoleon led to Moscow.

"After passing through this defile, we immediately entered the village, situated in a beautiful bottom, on the margin of a river, supposed, by some, to be main Red river, but which is only a principal fork of that stream.

"Like others of the southern rivers, its bottom is a flat bed of fine sand that maintains nearly the same level all the way across, the water now but a few inches deep; yet, unlike the water of other rivers, this is nearly as salt as the water of the Ken-hava saline. When this stream is full, it is 500 yards wide, and about ten feet deep. The natives say that the salt taste proceeds from great beds of rock salt about twenty miles above, and exhibited to us quantities that they had procured there. Our arrival here was timely; for we were hungry, and had nothing to eat. They had plenty of good corn just in good eating order, pumpkins, squashes, water and musk melons, together with dried Buffalo and horse meat. For supplies of these articles we gave them tobacco, tin cups, buttons, the yellow stripes from our pantaloons, &c.; but when we offered them money they laughed at us, for these unsophisticated beings knew not its value. When we could explain to them the use of any thing, they would trade for it; but as we could not make them sensible of the use of money, none of it would they have.

"They call themselves Towea Indians, and appear amiable and industrious. The women are beauties, yes, real first rate, light copper beauties, for devil take the ugly one that I saw, that was less than a "centurion," which word, a school mate of mine once defined to be a person one hundred years old, and got flogged for his pains.

"On the 23d and 24d, the Kiewa, Waco and Camanche Indians arrived, and our little band was surrounded by between three and four thousand warriors, yet we trembled not. On the 24th the treaty proceeded, and by it, among other things, we recovered from them a little white boy, the son of *Gabriel Martin*, a wealthy planter of Louisiana. He had gone up, with some friends, early last spring, on a hunting excursion to the False Washita, and whilst separated from the rest, was attacked by the Indians and killed, and his son taken prisoner. They concealed the boy on our approach, and he probably would never have been liberated, had it not been for a negro, likewise a prisoner, who informed us where he was concealed. He was seven or eight years old, and unusually intelligent."

INDIANA STATE LOAN OF 600,000 DOLLARS—5 PER CENT STOCK.—Viz. 400 thousand Dollars Bank Loan, irredeemable for 20 years, taken at a premium of 4 1-2 per cent., or 104 50-100 Dollars, for \$100 Stock.

200 thousand Dollars Canal Loan, part irredeemable for 25 years, and a part for 30 years, at a premium of 5 per cent. or 105 Dollars, for cash, \$100 Stock, was yesterday taken by Messrs. J. I. Cohen, Jr. & Brothers, of Baltimore, being a higher offer than any made by the New York capitalists.

[From the Albany Argus of yesterday.]

CHENANGO CANAL LOAN.—Yesterday was the day for opening the proposals for the Chenango Canal Loan of \$500,000 by the Commissioners of Canal Fund. The following offers were made for this loan, being 5 per cent. stock reimbursable after 1845, viz:

Thos. W. Olcott, Rich'd Yates, and Watts Sherman, a premium of 11 1-10 per cent.; the money loaned to be deposited in the several banks for which the bid was made, and the banks to pay in-

terest at the rate of 5 per cent. per annum for the deposits.

Prime, Ward & King, 8 per cent. premium for the whole loan.

J. J. Cohen, Jr. and Brothers, Baltimore, 12 per cent. premium for the whole loan.

Harman Hendricks, 12 per cent. for \$125,000, and to pay \$74,000 in 7 per cent. Erie and Champlain Canal stocks, at 24 per cent. premium, and the residue in cash.

The stock was awarded as follows, viz:—To J. J. Cohen, Jr. and Brothers, \$400,000.

To Harman Hendricks, \$100,000.

The premium on the whole loan amounts to the sum of \$60,000.

ARRIVAL OF THE EALMOUTH.—We learn from the Norfolk Beacon that the United States sloop of war *Falmouth*, *Charles S. McCauley, Esq.* commander, arrived there on Saturday, 1st August, in 17 days from Pensacola; officers and crew all well. The *St. Louis*, *Capt. Rosseau*, and the *Grampus* were both at Pensacola when the *Falmouth* sailed. The *Vandalia* was absent on a cruise to the Gulf of Mexico; and was expected to return to Pensacola about the 1st of August. We learn that the town and squadron enjoyed excellent health. It is expected that the *Grampus* will return to the North during the summer, as she is much in need of repairs. The other vessels will remain on the station.

The following is a list of officers attached to the *Falmouth*.

*Charles S. McCauley, Esq.* Commander.  
Lieuts.—*Wm. Pierson, Arch'd. B. Fairfax, Henry K. Thatcher, Charles G. Hunter.*  
Sailing Master—*Wm. Lambert.*  
Fleet Surgeon—*Leonard Osborne.*  
Assistant do—*W. A. Spotswood.*  
Purser—*Nathanial Wilson.*  
Passed Midshipmen—*Charles F. McIntosh.*  
Midshipmen—*D. Ross Crawford, A. S. Whither, J. W. Brackett, W. H. Carnes, G. W. Grant, N. Collins, S. C. Barney, E. J. Donnellson.*  
Captain's Clerk—*Leroy H. Anderson.*  
Boatswain—*Samuel Stanley.*  
Gunner—*Thos. Robinson.*  
Sail Maker—*Samuel V. Hawkins.*  
Acting Master's Mate—*Benj. Bunker.*  
Purser's Steward—*S. D. Moulton.*  
Passengers.—*Major Byrd C. Willis, Navy Agent at Pensacola; and Passed Midshipman Geo. W. McCreery.*

The Boston Daily Advertiser of Monday says, "the pleasure yacht *Wave*, *Captain John C. Stevens* (owner), arrived here on Saturday morning, from New York, for the purpose, so said, of engaging in a sailing match with the *Sylph*, of this place; but meeting with the *S. off Nantucket Shoal* on Thursday last, the trial took place on the spot, and resulted (as we are informed on board the *Wave*), in handsomely beating the *Sylph* in every position tried.

The Providence Journal also contains the following notice of "the *Wave*."—"A rare specimen of naval architecture made its appearance at Newport on Wednesday last. It was of about 93 tons burthen, schooner rigged, finished in a novel and beautiful style, and excited the admiration of all beholders; and is ready at all times to try its speed with any vessel in this country. A party of gentlemen, desirous of viewing the *Wave*, were received in a most cordial and gentlemanly manner by its owner and commander, *John C. Stevens, Esq.*, of New York, and its officers, Messrs. *Sands, Stevens*, and *Thompson*. It is expected the *Wave* will shortly visit this place, in company with the revenue cutter *Vigilant*; when those to whom we are incompetent to give any adequate description, may have an opportunity to see and admire its striking features."

COW CATCHING.—According to the Boston Journal, a circumstance, very near an accident, occurred to one of the railroad cars on Thursday evening, on its way from Providence, with the passengers of the Lexington. When in the farther part of Mansfield, they run into a drove of cattle, and soon found that their cow catcher which they have wisely placed on their night engine, had gathered together two of the herd, and was proceeding with them at a rapid rate, without any damage to the car or the knowledge of the passengers—till the engineer saw his new freight, and stopped to discharge.—[Gazette.]

MONUMENT BY THE BAR TO THE CHIEF JUSTICE.

The following proceedings of the Philadelphia Bar, with whom the happy idea originated of raising a suitable Monument to John Marshall, set forth the mode in which it is proposed to carry out the plan. They will be of interest to, and command the concurrence, of the New York Bar, which so promptly associated itself in the noble enterprise.

**MARSHALL MONUMENT.**—At a meeting of the committee appointed by the Bar of Philadelphia, on the 7th July, 1835, held at the Law Library Room, on the 31st of the same month, P. S. Duponceau, Esq., was appointed Chairman, and James C. Biddle, Esq. Secretary.

The following Resolutions were adopted:

Resolved, That a sub-committee be appointed to consist of five members, whose duty it shall be:

1. To proceed immediately to collect subscriptions for the Monument, from the bar of Philadelphia;
2. To cause subscriptions to be collected from the Bar of the other parts of Pennsylvania;
3. To promote subscriptions by the members of the Bar throughout the United States;
4. To correspond with such committees, and in individual members of the profession throughout the United States as may be authorized or disposed to co-operate with us in the proposed object.
5. To confer on the part of the Bar of Philadelphia, with such committees or individuals as may be appointed or authorized to confer with them on the subject of their appointment or matters connected therewith.
6. To adopt such other measures as may seem to them expedient and proper for furthering the contemplated purpose.

Resolved, That desiring to make the subscription as extensive as possible, and to avoid inconvenience to those who may be willing to unite with them, it is the wish of the committee that individual subscriptions should be moderate, and that the required amount may be made up by the number of contributors, rather than by the magnitude of particular donations, so that the Monument may truly be the work of the Bar of the United States, and an enduring evidence of their veneration for the memory of the illustrious deceased.

Resolved, That it is the desire of the Bar of Philadelphia, that all who may contribute, shall have a voice in selecting the plan to be adopted, and at a suitable time arrangements will be made to give them an opportunity, by their delegates, to take a part in the selection.

Resolved, That before a plan can be adopted, it is necessary to know the extent of the means that will be furnished, and therefore, it is earnestly requested that subscriptions may be collected and forwarded with the utmost possible despatch.

Resolved, That Samuel Jaudon, Esq., Cashier of the Bank of the United States, be the Treasurer of the Marshall Monument Fund, to whom all monies collected, are to be forwarded.

Resolved, That we sincerely hope that our brethren throughout the United States, will immediately and actively exert themselves, within their respective spheres, to collect and forward subscriptions, in such manner as may seem to them best.

Resolved, That the sub-committee be instructed to receive no subscription from any member of the Bar of Philadelphia, exceeding ten dollars, and to inform the members of the Bar throughout the United States, that this regulation has been adopted here.

Resolved, That the editors of the newspapers throughout the United States, be requested to publish these proceedings.

The following gentlemen were appointed the sub-committee under the first resolution:

Mr. Duponceau, Mr. Binney,  
Mr. Sergeant, Mr. Chauncey,  
Mr. J. R. Ingersoll.

P. S. DUPONCEAU, Chairman.

J. C. BIDDLE, Secretary.

**DANGEROUS BAGGAGE.**—Our readers will probably bear in mind a fire which took place some time since on the Camden and Amboy Railroad, by which a good deal of baggage was injured. The directors then expressed an opinion that the fire was caused by the ignition of Lucifer matches, a large quantity of which was found among the con-

tents of the baggage car. The following, from the Easton (Pa.) Argus, will show that the suspicions were not groundless:—[Sun.]

"**Fire in the stage!**—On Saturday last, Mr. H. Hummaun, received from Philadelphia by the stage a box containing books and stationary, and among the rest a box of Lucifer matches. It seems that the friction occasioned by the motion of the stage caused the Lucifers to ignite, but fortunately for the want of air the fire was smothered. The whole contents of the box smelt strongly of burnt matches though the damage was inconsiderable."

TEXAS VS. MEXICO.

[From the New Orleans Bulletin of July 18.]

TEXAS.—Captain Moore, of the schr. Shenandoah, in a short run from Brazoria, reports that the Texonians had seized upon the fort at Anahuac, garrisoned by one hundred men, whom they captured and sent to San Felipe. A portion of the people thought that this step was pushing matters to extremities, and as one uncalled for, but all were determined to maintain their just rights should they be assailed by the Mexican powers.

Schr. Shenandoah sailed from Brazoria on the 10th, and the Brassos Bar 11th inst., left no vessels—reports that the people of Anahuac on the 7th inst. rose upon the Mexican soldiers quartered in that place, and captured their fort, which was no sooner done, than they offered to desert Santa Anna and join the Texonians, but instead of receiving them the people drove them far into the prairies towards Nacogdoches—and also reports that the people on the Brassos river were organizing a military force to proceed immediately to the defence of the town of San Antonio—great excitement prevailed among all classes of the inhabitants.

**RUMORED DISTURBANCES IN COLOMBIA.**—The following paragraph is from the books of the Philadelphia Exchange. As there are no papers from that city to day, we have nothing in explanation, confirmation, or contradiction of it.

Extract of a letter from the American Consul dated St. Johns, P. R. July 17, 1835.

The disturbances on the Main continue, and have been of such a nature in Colombia, that the President and Vice President have left, and arrived at St. Thomas on Wednesday last—We have not learned the particulars.

**PICTURE OF AFRICA.**—It possesses not the charm of refined and intellectual society; its European inhabitants, with very few exceptions, professedly try to get money as fast as they can, that they may return to England; and yet when they do return, there is no place so dear to them as the land they have left. I could cite various examples of this, but two or three only will serve as a type for the rest. During our second voyage to Africa, we met with our dear friend Mr. M.—n; he was dying from consumption, and suffering dreadfully; and yet his pain, his approaching dissolution, were alike forgotten when Mr. Bowdich and myself would sit by his side and talk of the scenes and adventures we had known together in Fantee. The delicious fruits of Madeira were not to be compared with ours on the coast; the storms were not so grand; the hottest season there was much more intolerable; and the Portuguese servants not half so good as his own man, Black Jack, who used to beg him "not to take vex, but he wanted a bottle of wine particular;" the invalid's eyes would brighten, the color rush into his pale lips and cheeks, and a momentary strength would be imparted by these, and a multitude of happy recollections. Certainly no one ever suffered more in Africa than the intrepid Mr. Hutchinson, who died only a few months back at Leith, a victim to a northern, instead of a tropical climate; and yet he never was so animated or enthusiastic, in short so happy, as when recurring to the scenes of his past life. And so it is with myself. I have visited other lands, nay, lived in them, and my path has been broken and rugged. Still more thorny was it in Africa, and yet my thoughts and feelings incessantly recur with indescribable affection to those wild scenes; every minute circumstance vividly rushes before me as if it were the occurrence of yesterday, and my very dreams are of that magnificent land, where nature has lavished her treasures with such unlimited profusion. Perhaps these treasures form one of the secret links of that chain which binds us

all to her; and her lofty primitive mountains, her mighty rivers, her impenetrable forests, her deep blue sky where the sun and the moon sail in cloudless majesty, and banish all idea of darkness; the furious grandeur of her tempest; the strange and uncontrolled forms with which her wastes are peopled; her gay, laughing flowers; her juicy and exquisite fruits, which require no toil to bring to perfection; her children, rude and disgusting as many of them are, even form objects of compassionate interest, from the very curse under which they seem to labor; and all these, perhaps, create feelings in residents which, to those who have always dwelt in civilized nations, are inexplicable. There may be yet another cause, which is the constant excitement afforded by a life which often presents danger, and constantly requires contrivances for comfort and enjoyment.—[Mrs. Lee's Stories of Strange Lands.]

**FEROCITY AND FANATICISM.**—The less the designs of the Ismailites prospered by the sword the more successful and persevering were they with the dagger; and, however dangerous to the order the times might be, they were not the less so its most powerful adversaries. A long series of great and celebrated men, who during the grand mastership of Kiabusurgomid, fell by the pinnards of his Fedavi, signalized the bloody annals of his reign; and, as formerly, according to the fashion of oriental historians, there follows, at the end of each prince's reign, a catalogue of great statesmen, generals, and literati, who have either adorned by their lives or troubled it with their death; so, in the annals of the Assassins, is found the chronological enumeration of celebrated men of all nations who have fallen the victims of the Ismailites, to the joy of their murderers and the sorrow of the world.—The first under the grand-mastership of Kiabusurgomid was Cassim-ed-dewlet Akonker Boursli, the brave Prince of Mossul, feared alike by the Crusaders and the Assassins, as one of their deadliest enemies. Having fought his last battle with the former, near Maara Mesrin, he was, on the first Sunday after his return, attacked by eight Assassins, disguised as dervishes, as he was in the act of seating himself on his throne in the mosque at Mossul: protected by a coat of mail and his natural bravery, he defended himself against the wretches, three of whom he stretched at his feet; but before his retinue could hasten to his assistance, he received a mortal wound, from the effects of which he expired the same day. The remaining Assassins were sacrificed to the vengeance of the populace, with the exception of one young man from the village of Katernash, in the mountains near Eras, whose mother, on hearing of Akonker's murder, dressed and adorned herself for joy at the successful issue of the attempt, in which her son had devoted his life; but, on his returning alone, she cut off her hair and blackened her hair, with the deepest sorrow, so that he had not shared the murderers' honorable death. To such lengths did the Assassins carry their point of honor, and what may be termed their Spartanism. Moineddin, the vizier of Sultan Sandjar, was also murdered by an Assassin, bred by his enemy, Derkesina, the vizier of Mohammed, and a friend of the Ismailites. In order the better to attain his object, the ruffian entered his service as a groom. One day, as the vizier went into his stable to inspect his horses, the false groom appeared before him without clothes, in order to avoid all suspicion of carrying concealed weapons, although he had hid his dagger in the mane of the horse, whose bridle he was holding. The horse reared, and, under pretence of quieting him with cresses, he snatched his pinnard and stabbed the vizier. If Boursli, Prince of Mossul, stood on the list of the victims of the Ismailites, solely because he was a rival to their power and an obstacle to their greatness, we shall not be surprised at finding the name of Busi, the Prince of Damascus, by whose orders the vizier Masdeghani and six thousand Assassins had been massacred. The slightest pretence was sufficient to cause the blood of princes to flow beneath their stilettos; how much more when their own called, as in this latter case, for revenge. To escape was beyond the power of prudence, as they watched for years, for time, place, and opportunity. Busi, the son of Togtegin, was, in the second year after the massacre, attacked by his avengers, and received two wounds, one of which healed immediately; the other was, however, mortal the following year.—[Von Hammer's History of the Assassins.]

### Musings—By Flaccus in the Country. ELEGY.

MARSHALL!—Thy name is written on the rock,  
Where Freedom raised her standard in despair;  
But braved triumphantly the tyrant's shock,  
And drove the baffled lion to his lair.

For thee thy country mourns—departed worth!  
Whose hand upheld her from her childhood's years;  
For thee her guide, her guardian from her birth  
The grateful orphan sheds her generous tears.

Thine, is the double glory, to sustain  
The prize of Liberty, as well as vain;  
With open foes to triumph on the plain,  
And thwart the plots of treacherous friends within—

Yet some there are, would boldly blast thy name;  
(The base would e'er revile the noble dead)  
Or praise in whispers what they should proclaim—  
Foece! their curse, it cannot reach thy head.

Dogs bay the moon, but heaven's majestic queen  
Rolls on, regardless of the yelping crew—  
So shall thy fame shine on its course serene,  
Nor heed the hounds of malice that pursue.

Remnant revered of Freedom's holy band!  
Who linger'd long, yet bade, too soon, adieu—  
Ah! whether now shall turn thy widowed land?  
In danger's hour, whose hand shall guide her through

Feeble, and few, thy hoary mates appear,  
Who drank pure Freedom from her fountain-head;  
What now is left, to keep the current clear?  
What, save the bright example of the dead?—

In storms of war, in every civil strife,  
When license threatens Freedom with its blight;  
We'll up the spotless pages of thy life,  
And read the lesson that shall lead us right—  
No. 7. W.

**CIRCULAR.** To ENGINEERS and Superintendents of Railroads and Canals.—I am preparing to issue a new edition of my RAILROAD AND CANAL MAP; and being desirous to correct the errors of the first edition, take the liberty to request the ENGINEER, or SUPERINTENDENT, of every Railroad and Canal in the UNITED STATES, to furnish me at his earliest convenience with a full and precise account of the condition of the railroad under his direction or charge. He is requested to state the length of the road, the number of miles completed, the elevation it surmounts, the radius of its curves, the style of its construction, its average cost per mile, the number, if any, of inclined planes, with stationary engines—in short, every thing which may be of interest to engineers, or others who may be connected with the subject of Railroads and Canals.

To such as comply with the above request, and furnish the desired information previous to the first of August next, a copy of the new edition of the Railroad and Canal Map, will be sent, by mail or otherwise, as may be directed, as soon as completed.

D. K. MINOR.

New-York, June 27, 1835.

### RAILROAD JOURNAL AND ADVOCATE OF INTERNAL IMPROVEMENTS.

This work is published once a week, in quarto form of EIGHT pages, devoted mainly to the subject of internal improvements, in all its various modes and forms.

Three volumes were completed in December, 1834, and the 4th volume is now in progress.

Terms, \$8 a year, IN ADVANCE. Previous volumes same price; full set of four volumes, \$32.

### RAILROAD AND CANAL MAP.

Or a Map of the United States, 24 by 40 inches, on which is delineated all the Railroads and Canals in use, or in course of construction, and most of those in contemplation; together with a concise description of, or reference to, each, and containing over 70 pages of letter press. The map is on bank note paper, and put up in pocket form, with Morocco cover, or in paper cover, and may be sent by mail to any part of the country Price \$3.

### MECHANICS' MAGAZINE, AND REGISTER OF INVENTIONS AND IMPROVEMENTS.

This work has nearly completed five volumes. It is published monthly, in numbers of 64 pages each, in large octavo form, and forms two good sized volumes a year, of 384 pages each.

This work is STEREOTYPED from the first number, and therefore any number of copies may be obtained from commencement, if desired. It has many able correspondents, who furnish original communications, in addition to its selections from the best European periodicals of the day, with numerous engravings and illustrations of the subjects on which it treats. The Mechanics' Magazine may be considered as one of the permanent periodicals of the country. Price, \$3 per annum, IN ADVANCE. Previous volumes \$1.50 each.

### THE APPRENTICE'S COMPANION—

A monthly publication, in large octavo form, of sixteen pages each number—designed to persuade APPRENTICES, and others, to habits of INDUSTRY, TEMPERANCE, and FRUGALITY—is published at the office of the MECHANICS' MAGAZINE, No. 35 Wall street, New-York, for FIFTY CENTS a year—for 12 numbers—by D. K. MINOR.

\* \* All letters must be postage paid. Eleven num-

bers sent to one address for \$5,—and TWENTY THREE for \$10. D. K. M.

### NEW-YORK FARMER AND AMERICAN GARDENER'S MAGAZINE.

This work is devoted mainly to AGRICULTURE and HORTICULTURE; it, however, treats upon various other subjects more or less connected with them. It is now in its 8th volume, or 3d volume, new series, and is designed to be made equal to any work of the kind in this or any other country. No reasonable expense will be spared, either to secure the best writers the country affords, or to furnish engravings and illustrations. It is published monthly in large octavo, 32 pages per month, at \$3 per annum, and when paid in advance eight additional pages per month are given—Vols. 6 and 7, or 1 and 2, new series, \$3 per volume.

These works may all, or either of them, be had of S. Bladenburgh, 96 North Pearl street, Albany; D. Yale, 144 Washington street, Boston; Fessenden, Philadelphia; or of the Proprietor and Publisher, D. K. MINOR, 35 Wall street, New-York.

### PARTNER WANTED.

Wanted, a partner in an extensive Printing Establishment. No one need apply who is not a thorough printer, competent to superintend and direct an office in which upwards of 30 persons are employed, and able to furnish \$3000 cash capital. The best of references will be given and required. Letters, with real name, may be addressed to P. P. P., Post Office, New-York, postage paid, and they will be promptly attended to. May-17

### NOTICE

I hereby given, that an Assessment of Ten Dollars on each share of the Capital Stock of the Boston, Norwich and New London Railroad Company, has been laid payable on the 18th day of August, 1835, at the Office of the Company, No. 52 Wall street, New York, or at the Quinebaug Bank, Norwich.

THOMAS ROBINSON, Treasurer.  
Norwich, July 11th, 1835. jy.16. 1A13

### NOTICE TO CONTRACTORS.

Sealed Proposals will be received at the Hudson and Berkshire Railroad Company's Office, in the city of Hudson, until the 5th day of September next, for excavating and embanking 14 miles of their Road from Arnold's shop, near Great's, at Chatham Four Corners, to the state line, and also for constructing 8 Bridges, from 60 to 70 feet each, between the abutments. Plans of the masonry and superstructure of the bridges will be exhibited at the Railroad Office. Contractors will be required to furnish all the materials for bridges; and the masonry to be completed by the 1st of December next. The road to be graded for a double track, 24 feet wide. A part of the road will be heavy rock and gravel excavation. Profiles of this part of the route will be exhibited at the Railroad Office, in Hudson, and also at the Office of the Engineer, at Chatham Four Corners. The road will be divided into sections of one half and one mile each in length, and prepared for examination by the 10th of August.

Proposals will also be received for furnishing 500,000 feet, B. M., of White Oak Rails 6 by 7 inches square, and 16 feet long. Also, 15,000 Oak, or Chestnut Ties, 6 by 7 inches square, 8 feet long, or, if round, not less than 8 inches in diameter, at small end. Also, 500,000 feet of Chestnut, Pine, or Hemlock Sills, 4 by 10 inches, 12, 14, or 20 feet long.

The whole to be subject to the inspection of the Engineer, and to be delivered on the line of the road, by the 15th of April, 1836.

The remaining 18 miles of the route will be put under contract as soon as the line can be prepared.

Persons applying for contracts will be expected, unless personally known to the Engineer, to present with their proposals recommendations as to ability to perform their contracts.

Any information on the subject afforded at the Engineer's Office, Chatham Four Corners.

JAMES M'ELLEN, President.

GEORGE RICH, Chief Engineer.

Hudson, Aug. 1, 1835. 31—St

### TO TUNNEL MINERS, DRILLERS, &c.

Wanted, immediately, 80 Tunnel Miners, (Cornish Miners will be preferred,) 80 Drillers, 50 Laborers, and two experienced Mine Blacksmiths, on the New York and Harlem Railroad, about five miles from the City. Liberal wages will be given, and cash payments made every fortnight. Apply at Mr. FOWLER'S, St. John's Hall, Frankfurt street, New-York.

JOHN BUTTER, Contractor.  
The Albany Argus, Philadelphia U. S. Gazette and Pennsylvania, will please copy this, and send their bills to the Railroad Company, 14 Wall street, New-York. 23—tf

### RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order car wheels, chairs and knees, and every other description of castings required for railroads. R-ly feb14

### PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

Railroad Spikes of every description required, made at the Albany Spike Factory.

Spikes made at the above Factory are recommended to be public as superior to any thing of the kind now in use.

Ship and Boat Spikes made full size under the head, so as not to admit water.

Orders may be addressed to Messrs. ERASTUS CORNING & CO., Albany, or to THOMAS TURNER, at the Factory, Troy, N. Y. sep.18-17

### STEPHENSON,

Builder of a superior style of Passenger Cars for Railroad,

No. 264 Elizabeth street, near Bleecker street, New-York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. J35tf

### RAILROAD CAR WHEELS AND BOXES, AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS.

Also, Flange Tires turned complete.

J3 ROGERS, KETCHUM & GROSVENOR

### RAILWAY IRON.

95 tons of 1 inch by 1/2 inch,	Flat Bars in lengths of
200 do. 1 1/2 do. do.	14 to 15 feet, counter sunk
40 do. 1 do. do. do.	holes, ends cut at an angle
900 do. 2 do. do. do.	of 45 degrees, with splicing
800 do. 3 do. do. do.	plates and nails to suit.

soon expected.

250 do. of Edge Rails of 36 lbs. per yard, with the requisite chairs, keys and pins.

Wrought Iron Rims of 30, 33, and 36 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels.

Axles of 24, 25, 26, 3, 34, 34, and 34 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment.

A. G. KALSTON,  
9 South Front street, Philadelphia.

Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them. d71meowr

### SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by

E. & G. W. BLUNT, 154 Water street, corner of Maiden lane.

### SURVEYING AND ENGINEERING INSTRUMENTS.

The subscriber manufactures all kinds of Instruments in his profession, warranted equal, if not superior, in principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Goniometer, with two Telescopes—and a Levelling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes.

WM. J. YOUNG,

Mathematical Instrument Maker,  
No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested.

In reply to the inquiries respecting the instruments manufactured by me, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish the following information. The whole number of Levels now in possession of the department of construction of the make is seven. The whole number of the "Improved Compass" is seven. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accidents to which all instruments of the kind are liable.

I have found that the patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a reversing telescope, in place of the vane sight, leaves the engineer scarcely anything to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,

JAMES F. STABLER, Supt of Construction of Baltimore and Ohio Railroad.

Philadelphia, February, 1835.

Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Germantown, February, 1835.

For a year past I have used Instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these Instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for the purpose.

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, AUGUST 15, 1835.

**GRAND JUNCTION RAILWAY.**—We devote in this number almost the entire space usually devoted to internal improvements, to the Report of JOSEPH LOCKE: It will be found worthy of an attentive perusal. We are indebted to the Directors of the New-York and Erie Railroad Company for a copy.

**NEW-YORK AND ERIE RAILROAD.**—We would call attention to the proceedings of the Railroad Convention held at Oswego, published in this number of the Journal. It was well attended, and attended, too, by delegates from Oneida county—from whence came much of the opposition in the last Legislature. That "truth is mighty and will prevail," in this, as in most other important matters, we have never doubted; and it is truly gratifying to those who look at, and advocate, this as a national work, to learn that there are daily and important conversions to its cause from its former opponents.

**TROY AND BALLSTON RAILROAD.**—We learn, by the Ballston Gazette, the Railroad from the city of Troy to that village is so far completed, that the new engine with a train of passenger cars will arrive there on Thursday or Friday from Waterford. Thus it is that one railroad after another is brought into use; and it will not be many years before the mode of travelling on all the great thoroughfares will be by railroad and steamboat.

**PITTSBURGH.**—The river is three feet above low water mark.

[From the Oswego Palladium.]

**COMMERCE OF OSWEGO.**—We lay before our readers the following statements obtained from the Custom House, relating to the navigation and commerce of the port of Oswego. We simply remark that these statements exhibit only the business of the port as connected with the navigation of the Lakes, and exhibit nothing of the immense increase of business connected with the Oswego and Erie Canals.

Second quarter of 1835.

	Tons.
American vessels entered from foreign countries	13,140
" " cleared for do do	12,672
" " entered from ports of the United States	18,231
" " cleared for do do	19,792
	63,735
Foreign vessels entered from foreign ports	23,041
" " cleared for do do	23,103
	46,154
Total foreign and domestic entries and clearances	109,879
Amount of duties collected, \$14,310 64.	

On comparing the transactions of the Custom House for the above quarter of the current year with the corresponding quarter of the year 1834, we have arrived at the following results, which we state in round terms:

The increase of American tonnage clearing for and arriving from foreign ports, is nearly 1500 per cent.

The increase of foreign tonnage arriving from and clearing for foreign ports, is 39 per cent.

The domestic entries and clearances for the 2d quarter of 1834, cannot conveniently be ascertained—but the increase for the corresponding quarter of the present year is known to be very great.

The increased amount of duties collected is nearly 1300 per cent.

The increased amount of imports is nearly 600 per cent.

And the increased amount of exports exceeds 700 per cent.

We have not now schooners enough to do the business of our lake, and there is every reason to believe that we shall have double the business next year that we have this. Where shall we find vessels to do it? Every schooner now which is well managed clears from fifty to one hundred per cent. on her cost yearly. No better investment can be made. We have timber in abundance—and when the business is such that they will pay for themselves every year or two, why can we not have a sufficient number to do all the freighting that may be required by the commercial operations of our lakes.

**THE BOSTON AND PROVIDENCE RAILROAD.**—Increased facilities to travellers are afforded by the

new arrangement of running three times a-day over this road. The change of hour to four o'clock, P. M., for the departure of the New York steamboats from Providence, will be found, it is thought, convenient to passengers from Boston, who may then take an early dinner in that city, and arrive here the next morning before business commences.

In the deep cut of the Chesapeake and Delaware Canal, a slide took place, during the recent rains, which will, says the National Intelligencer, entirely obstruct its navigation, for some time to come, and cost a large sum to remove. The Baltimore American, however, of yesterday, says the damage is not so great, and that two sloops had since passed through.

Several of the steam carriages of the British and American Intercourse Company have been running in the vicinity of town this week, in particular from Hyde-park-corner to Slough, which (21 miles) is regularly done in an hour and 30 minutes.—Among the passengers have been Lord Darlington, Sir Hussey Vivian, Sir John Elley, Sir Henry Hardinge, Sir John Lambert, Sir Charles Dance, Colonel Grove and Thornton, Major Handley, M.P., and Mr. Cayley, M.P.

**STEAM CARRIAGES.**—Some of the members of the committee of the House of Commons now sitting, on steam carriages, having expressed a wish to be enabled to judge for themselves as to the practicability of a power so long suspended by legislative prohibition, in the shape of tolls, were invited a day or two since by Col. Sir Charles Dance, who is just returned from the continent, to accompany him in his steam-carriage on a trip to his house at Hartford, near Stanmore. The invitation being accepted, the carriage started with a party from Oxford street, at half-past nine in the morning. At Hartford a *déjeuner* was provided by the care of Sir Charles; after partaking of which, and witnessing some experiments in drawing heavy weights by a steam-carriage, (with a view to military purposes,) the party set off on their return to Oxford street, which they reached at half-past twelve, having accomplished the distance in forty-five minutes. On the journey out, the carriage went up Stanmore hill at the rate of eight miles an hour, although this is an ascent where the mail and stage coaches generally make use of six horses. Besides Lord Darlington and other members of the committee, the Master General of the Ordnance and several other distinguished persons were of the party.

**RESPECT FOR THE ARTS.**—A Danish fifty-gun frigate has arrived at Leghorn, to take on board and convey to Copenhagen a part of the finished works of Thorwaldsen. The artist himself intends to go to Copenhagen during the summer, in order to be present when they are put up in the places for which they are intended.

*Report of Joseph Locke, Chief Engineer of the Grand Junction Railway between Birmingham and Liverpool, Eng.*

To the Directors of the Grand Junction Railway Company,  
GENTLEMEN:

In submitting for your consideration the following remarks on the subject of Rails and Chairs, I wish briefly to state the reasons that have induced me, (after you have already decided on the form of Rail,) to investigate the question. Under ordinary circumstances, I might have been justified in simply giving a preference to a particular form of Rail, without stating the grounds on which that preference was founded, but considering the present conflicting opinions on this very important subject, and the scarcity of data upon which to form a correct judgment, I have thought that by contributing the few observations I have made to the general stock, the cause in which you, as well as the public, are interested, might be advanced.

The longitudinal and transverse forms of Rail, the form of Chair and fastening, and the propriety of placing the Blocks further apart, are the subjects to which I have more particularly directed my attention.

The fish-bellied or elliptical form of Rail is already well known. It is deepest in the middle between the supports, and the material is so disposed that when uniformly loaded it is equally strong at all points.

The parallel Rail, on the contrary, is weakest in the middle, and, if loaded excessively, would break midway between the supports; and as it is absolutely necessary to give the requisite strength in the middle, it follows that at every other part the parallel Rail is unnecessarily strong.

The strength of a uniform bar of iron is as the breadth and square of the depth directly, and as the length inversely. In other terms, if the breadth be doubled, its strength is doubled; if the depth be doubled, the strength is quadrupled; and if the length or distance between the supports be doubled, then the strength is impaired one half.

If an elliptical Bar be  $3\frac{1}{2}$  inches at the least, and 5 inches at the greatest depth, a parallel Bar of equal weight will be about  $4\frac{1}{2}$  inches, and the relative strength in the middle, (supposing the breadth and distance between the supports to be constant,) being as the square of the depth, will be as 25 is to 18.

This advantage, however, is only gained at one point, viz. midway between the supports; and it gradually diminishes, until it corresponds in depth with the parallel Bar, which, when the supports are 3 feet apart, is at 9 inches from the end, and at this point the two Rails are equally strong: but for the remaining distance to the support, the parallel Bar is the strongest.

I am aware that, theoretically speaking, the extra strength of the parallel Rail near the ends is of no advantage, because, as has been well observed, the efficiency of a structure can only be estimated at the weakest point,—but I wish that circumstance to be noticed, as I shall have occasion hereafter to direct your attention to it.

The formula for ascertaining the strength of iron beams are derived from experiments made upon peculiar sections, and with various kinds of iron. Some experiments have recently been made at Newcastle, on the strength of Railway Bars, and these therefore are more applicable to our purpose than any others, although they are not altogether free from objection. The deductions, which I think are very fairly drawn from these experiments, are,

That an elliptical Rail weighing 45 lbs. per yard is equal in strength to a parallel Rail weighing 50 lbs. per yard.

That when a weight of 96 cwt., was applied in the middle, with 3 feet bearings, the deflexion in the former was 1.20th of an inch, and in the latter 1.14th part of an inch,

The depth of the fish-bellied Rail in the middle was 5 inches, and at the end  $3\frac{1}{2}$  inches. The depth of the parallel Bar was 4 inches.

Now if the two Rails had had similar sections, the parallel Bar ought to have been  $4\frac{1}{2}$  inches deep, instead of 4 inches, and would have been 1.8th stronger.

However, I think there can be no doubt that, both theoreti-

cally and experimentally, of the two Rails with similar sections, the elliptical, with the same quantity of material, is strongest form.

But the question for consideration is, whether from the construction of Railways, and the effect of heavy bodies rolling along them at high velocities, we can safely apply theoretical or even experimental deductions? For my own part, I think that the experience obtained from the working of the Liverpool and Manchester, and other Railways, affords much safer data upon which to proceed; and although I would not reject experimental data, I would only apply it in connection with the more generally practical results obtained from these lines.

It is well known that a very considerable number of the elliptical Rails on the Liverpool and Manchester line has been broken, whilst on those lines where the parallel Rails have been used, there are few instances of a broken Rail. The causes that have led to this unexpected result will hereafter be considered.

By far the greater number of Rails have broken at about 7 or 8 inches from the Block, and, in nine cases out of ten, at 7 or 8 inches from the joint Block, or end of the Rail. This circumstance has induced a belief that the Rail is not of the true elliptical form, but that it is weakest at this point; it will, however, be found that the point where the greatest deviation from the elliptical form occurs, is not that at which the fractures have generally taken place.

The Rails used on the Liverpool and Manchester Railway weigh 35 lbs. per yard—the greatest depth is  $3\frac{1}{2}$ , least depth  $2\frac{1}{2}$ ; now, the effect of any weight at different parts of the Rail is as the rectangle of the segments into which it is divided. If therefore it be necessary to have a 3 feet Rail,  $3\frac{1}{2}$  inches deep in the middle, the depth at nine inches from the end will be as  $18^2 : 8 \times 28 :: 3\frac{1}{2}^2 : 2.01^2$  inches; but the actual depth is 2.94 inches, therefore it is at this point about 1.30 of an inch too deep. The calculated and ascertained depths at other parts of the Rail are:

	Calculated depths	Actual depths.
At 6 inches from the end,	2.60	2.76
7	2.77	2.85
8	2.91	2.94
9	3.03	3.02
10	3.13	3.10
11	3.22	3.20
12	3.29	3.30
13	3.36	3.36
14	3.41	3.40
15	3.45	3.44
16	3.47	3.46
17	3.49	3.49
18	3.50	3.50

Thus we find, that up to 9 inches from the end the Rail is stronger than theory assigns, whilst from 9 inches to 12 it is a little weaker, but in so small a degree as not to be worth considering. The depth of the Rail, at 9 inches from the end, is equal to the depth due to a parallel Rail of the same weight per yard. And if the Liverpool Rails had been parallel instead of elliptical, and of the same weight, the fracture, instead of being near the end, would, according to theory, have been in the middle, and the number of broken Rails increased in the proportion of nearly 2 to 3. There have been no parallel Rails exactly of this weight made; therefore, whether this proportion would hold true in practice remains undetermined. If, however, a parallel Rail had been used, as deep in the middle as the elliptical Rail now is, viz.  $3\frac{1}{2}$  inches, its weight would have been about 42 lbs. per yard, and the number of broken Rails ought to have been the same, the point of fracture only being changed.

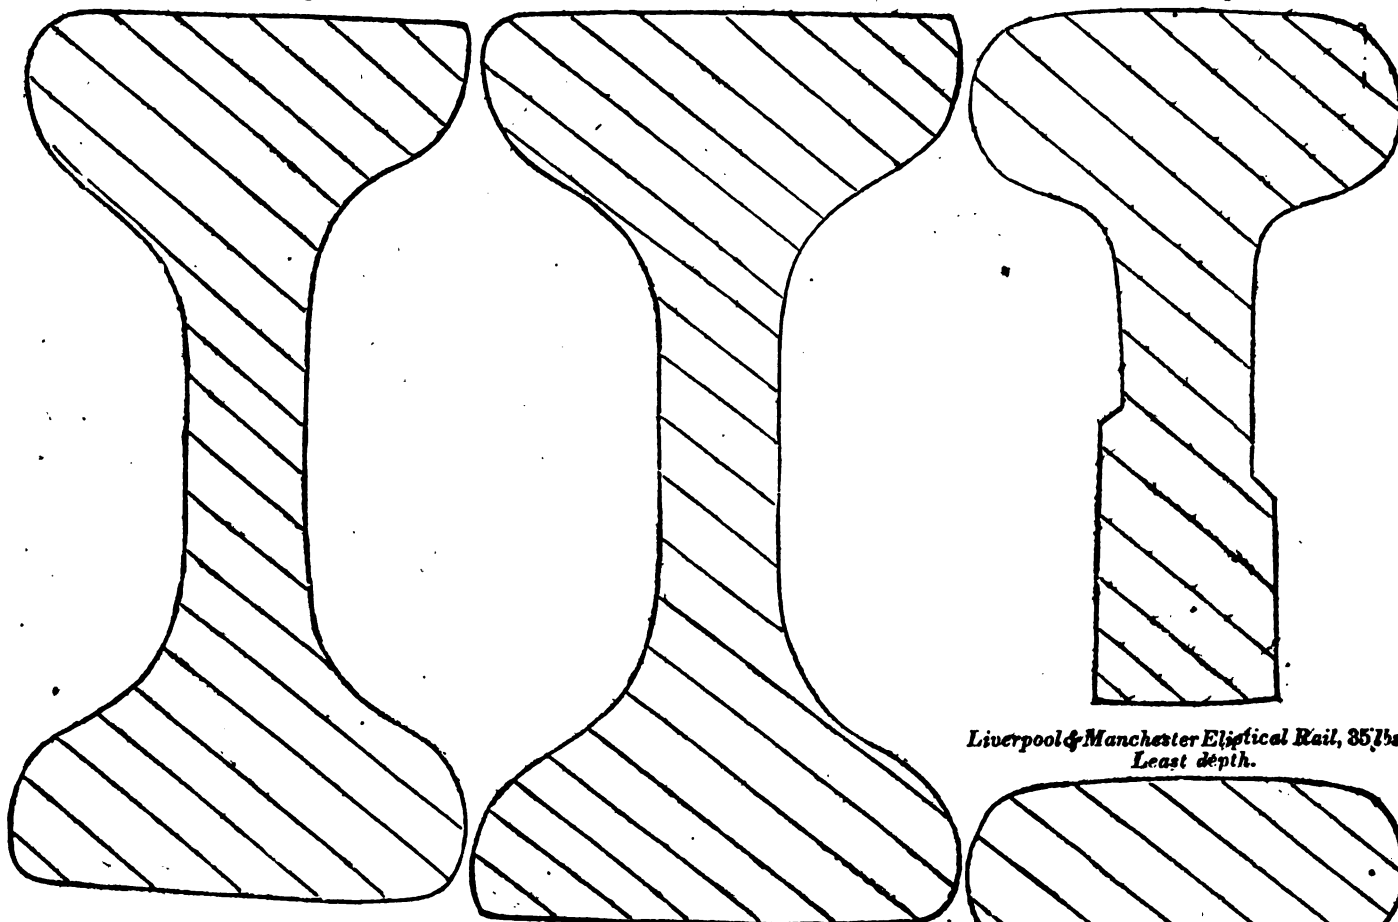

This reasoning, theoretically speaking, would be conclusive, had we not the experience of the Bolton, Wigan, St. Helens, and part of the Liverpool and Manchester Railways, wherein such Rails have been used, and where very few have yet been broken.

These Rails weigh  $41\frac{1}{2}$  lbs. per yard and are  $3\frac{1}{2}$  inches deep. May we not therefore fairly conclude that experience does not bear out the theoretical advantages of the elliptical Rail?

*Present Grand Junction Railway,

*Liverpool and Manchester Elliptical Rail, 50 lbs  
Least depth.*

*Mr. Stephenson's Elliptical Rail, 44 lbs.*

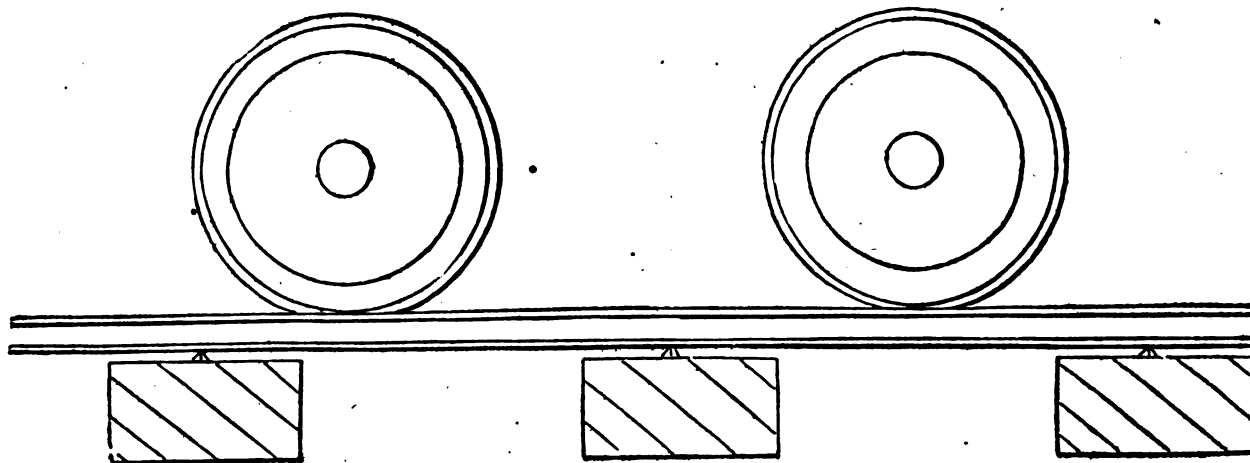

*Liverpool and Manchester Parallel, 60 lbs.**Liverpool and Manchester Parallel R. at, 50 lb. s.**Dublin Parallel, 45 lbs.**Sketch with 3 feet bearings, showing the undulations of the road with certain depressions of the blocks.**Six feet bearings, showing the undulations with similar depressions of the blocks.**Three feet bearings, showing the position of a pair of carriage wheels 7 feet apart.*

*Five feet bearings, showing the position of a pair of carriage wheels 8 feet apart, one wheel being over the block.*

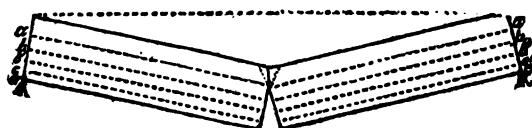

*Same as the above, one wheel being over the centre of the rail.*

The chief causes of failure may, in my opinion, be traced to the defect in fastening the Rail into the Chair, and the difficulty of preserving the uniform level of the Blocks. An attentive consideration of the effect of a heavy body moving along a railway will sufficiently prove this. From the unequal settling or subsiding of the ballast, the level of the Blocks becomes unequal, and so soon as one becomes lower than its neighbors, every wheel that passes over it strikes a blow and drives it lower. The force of this blow depends on the depression of the Block, which not unfrequently exceeds half an inch. When this occurs, the weight of the load is alternately thrown to the inner edges or arrises of the adjoining Chairs; and thus not only is the weight thrown on one side of the Block, but a considerable strain is given to the longitudinal key. In some cases there is an alternate action, first on one side of the Block and key, and then on the other, thus producing a rocking motion to the Block, which very soon alters its level, and to the key a fretting motion, which soon shakes it loose. When the latter is accomplished, the Rail which has very little substance at the bottom is liberated; and it is then, and I believe not till then, that the Rails break, for it has been well ascertained that a beam, fastened at the ends, will bear nearly double the weight that will break it when the ends are loose. And this view is confirmed by the fact, that, in nine-tenths of the Rails hitherto broken, the fracture has taken place near to the ends.

Another cause of the failure of the fish-bellied Rail arises from the want of an under-web. It is well known that the strength of beams is increased by adding to the substance at the bottom, and this increase will be found to be much more important when the Rail is subjected to blows, rather than to weights laid or rolled smoothly along its surface. The fibres at the bottom of a beam are more strained than those in the

middle, because they lie at a greater distance from the neutral axis.\* This will be best understood by a reference to

the drawing above, where a fractured beam is represented. The line *a a* represents the neutral axis; the lines *b b*, *b' b'*, &c. the position of the fibres of iron or other material dividing the beam into several pivots. Now the extension of the fibre at *c' c'* is to that of any other fibre as its distance from the neutral axis, and it follows that at *c' c'*, where the distance is greatest, the elasticity of the material will be first destroyed. This, therefore, is the point where the greatest number of fibres is required, and more particularly to resist a sudden shock, or blow; for, in this case, the elasticity of the lower fibres might be destroyed before those placed nearer the neutral axis had been called into action. The same may be said of the fibres above the neutral axis, which resist by compression; the upper fibres of the Rail being further from the neutral axis are more compressed than those below them. The position of these fibres may be compared with the bundle of sticks in the fable: place them in such a manner as to allow them to act together, and they will resist the load, but take them singly, and each will break. A deep narrow bar is certainly the most rigid, but, (as Tredgold has well observed,) although it will bear an immense pressure, the stroke of a hammer will fracture it.

\* The neutral axis, or axis of motion, is in that part of a beam where all the fibres above it are compressed, and all those below are extended. It is situated above the middle, but varies in differently shaped beams, and with different qualities of material.

This view of the subject leads to the conclusion, that to increase the depth without reference to the breadth of projection on the underside, is not the way to obtain the best Rail-way Bar; and it is to this under-web in the parallel Rail, small as it hath hitherto been, that its superiority is in some measure to be attributed. The obvious remedy for this defect in the elliptical Rail would be to give to it this projecting web, but this, even if practicable, could only be accomplished with difficulty.

This comparative view of the two forms of Rail refers only to the condition that the bearings be 3 feet apart, and the saving of iron, in this short length, is not so much as would appear from a comparison instituted with 6 feet bearings. I have no doubt that with the Blocks much further apart, the elliptical Rail, by the addition of an under-web, might be used successfully and economically; but until some means be found by which an under-web can be given to the elliptical Rail, I think we ought to confine ourselves to the parallel form.

So far, therefore, as the longitudinal form is concerned, I am favorable to the parallel Rail, and the transverse section which I would recommend is that in which, after allowing sufficient width for the carriage wheels to roll upon, a moderate thickness of the rib, (due regard being had to the height of the chair,) all the remaining substance should be thrown into the under-web. It was with this view that I formed the model which you have already adopted, and which has also been adopted by the North Union Railway Company; and taking into consideration a suggestion made after much experience by Mr. Sinclair, that it would be desirable to be able to turn the Rail upside down, should the upper surface become defective, I decided upon making the upper and lower Rails precisely similar; but this has been accomplished without impairing its strength. It has been stated that this contingency of turning the Rail is "dangerous, and done without foresight;" but, (unless it be shown that some benefit is sacrificed,) I cannot see why this project should be so named.

If a Rail be not similar, top and bottom, it is evident that we are confined to one side, which, when it becomes worn or imperfect, is useless, and the Rail must be sold as old iron; but if it will turn, even supposing it to have been so much worn as to be too weak for the purposes to which it may have been before applied, may still be used on sidings, or branch lines, where the engines are lighter, or the speed not so great. That there is an advantage in being able to turn a Rail, even to make choice of sides, when first laid, is well known to those who have laid them, and therefore this contingency should not in my opinion be so totally disregarded. In preparing this, and the model for the chair, I have had three objects in view.

Firstly, Whilst giving the Rail a sufficient bearing surface on the Chair, so that one shall not groove or cut the other, I propose to reduce the length of the bearing at least one half, by which the tendency to rock the Block, and tear off the Chairs, will be reduced 50 per cent.

Secondly, To prevent the Rail from rising in the Chair, which is proposed to be accomplished by the large projection on the Rail, the filling piece, and the wooden key: which, so long as either of the latter keep their places, will prevent the Rail from lifting up.

As to the liability of loosening the key, I

ling piece shall only touch the Rail for of the centre of the Chair, instead of fore; so that by any flexibility of the Blocks, the action on the key will be and that continual fretting or tremor, to the long iron keys now in use, will proportion.

two filling pieces and two keys, the sure a more certain hold of both Rails, one by one key. Each key acts independently, and therefore any working loose of easily, as at present, liberate the other. nitted to make an observation on the wards of 8 months since you instructed with wooden keys on the Liver-

pool and Manchester line, and I caused about 100 yards to be laid, adapting the key to the Rail and Chair when in use. The objection raised at the time was, that wood was not sufficiently durable, and that it would decay and become chafed by the working of the Rails in the chairs, and thus be worked loose. I was quite aware that this, to a certain extent, would be the case, although I believe not so much as materially to affect the stability of the fastening. I have just examined these keys, and have great reason to be satisfied with them. There is a joint Rail or two which rises in the chair, but this is caused more from the want of substance in the Rail to hold it down, than from the key; some of the keys would bear tightening, others would not, but none were loose; I at the same time examined the Rails laid down under the direction of Mr. Stephenson, and found them in very good order; there are but a few lengths laid, but these were upon the whole very firm and solid. I was induced to try the wooden keys, because I believed those of iron were worked loose by the jarring and fretting motion produced by the passage of every carriage over them. There is not sufficient elasticity in iron thus applied, to yield or adapt itself to the strain which the changed position of a Rail, when deflected, throws upon it, and, therefore, wherever this evil exists, iron keys will ultimately work loose. There is more yielding in wood, which adapts itself more uniformly to the side of the Chair against which it presses, and does not, like the iron key, touch only in points; and by making the recess in the Chair smaller in the middle, and using the wood quite dry, the projecting part of the key expands, by absorption of moisture from the atmosphere, and is thus prevented from being worked or drawn out. It is similar in principle to a cork in a bottle, the middle part of the Chair, like the neck of the bottle, being the smallest. It is quite evident, that the decay from long exposure to the weather is the only thing to be guarded against, but I maintain that, if they but last two or three years, they will be found to be economical. Wooden sleepers are not more durable than stone Blocks, but still they are used. Why should not wooden keys last as long as sleepers? There must also be less noise from a train where wooden keys are used; the reason is obvious, for the substitution of a softer material between the Rail and Chair prevents the vibrations of the former from being communicated to the latter.

The successful application of wood for keys is very important, and I regret that these keys were not practically tested when I first suggested them, (now upwards of two years since,) but I shall continue to watch the operation upon that part of the Liverpool line now laid with them, so that we may yet take advantage of any change that time may produce.

I come now to consider the propriety of placing the Blocks at a greater distance from each other.

The reasons that have induced me to recommend this to your consideration are not strictly confined to economy, (although I shall be able to show some advantage on that score,) but to a conviction that much of the wear and tear, not only of the Rails and Chairs, but of the engines and carriages, will be avoided. There is one point to which I wish to direct your attention, viz.: That so long as the Blocks are not placed further apart than the axles on the carriages, no more weight can ever at one time be placed on one Block; and therefore the Blocks do not by this suggested change require to be larger, nor the foundations to be firmer, than they are at present. An inspection of the drawings will render this apparent.

If a carriage bear upon each wheel a load of 3 tons, it presses when immediately above the Chair with that weight upon the Block. The Block and the foundations should therefore be prepared to resist this load; now, if the Chairs were placed 2 feet apart, or the Blocks put close together, so as to touch each other, the very same weight must be borne to each Block and foundation; in short, however close the Chairs are placed, they must each bear the weight of the wheel when it comes perpendicularly over it. From this it would appear, that if the axles of the carriage be 8 feet apart, the Blocks might be 6 feet apart, without requiring to be larger, or the foundations to be better made.

The axles of the coaches and waggon now in use are

about 6 feet apart, none less than 5 feet, whilst the Blocks are 3 feet; the injurious effect of this arrangement upon the machinery and road, I will now endeavor to show.

It may have been remarked by the Directors, that on some parts of the Liverpool and Manchester Railway, the engines and coaches have, when in full speed, a very considerable swinging motion, which I believe arises from the inequalities in the road. Instead of the surface of the Rails being uniformly smooth, they offer to the carriage wheels a series of inclined planes or waves, and the Blocks immediately opposite to each other not being equally depressed, the carriages work upon the springs, and produce the motion already mentioned. Now, the intensity of this motion will depend upon the quick succession of change in the level of the Blocks, and if one Block be sunk half an inch, and the adjoining one not at all, the Rail will be inclined at the rate of 1 in 72. If, again, the next succeeding Block be not depressed, the engine has again to rise up an inclined plane of 1 in 72. In some instances the opposite Rail is inclined just in the opposite direction, in which case we have the two opposite wheels of an engine, one running down hill, and the other up. This I believe is no exaggerated picture, and it is not confined to the Liverpool and Manchester road; but will occur wherever the bearings are so much shorter than the coupling of the wheels. It was the undulating appearance combined with the motion of the engines, (which I have observed on all the newly constructed Railways,) that first drew my attention to the subject; and I have so far considered it important, as to believe that many of the evils hitherto experienced may be traced to it. The causes producing these effects are obvious. The ballast, as I have before observed, settles unequally. The first settling is assisted by the force with which the engines strike the Rail, and this increases as the Blocks settle lower. The foundations being unequal, some Blocks sink more than others, and at high velocities, the engines, instead of gliding smoothly along the Rail, actually jump from joint to joint, and where the depression is half an inch, will jump 20 inches without touching the Rail. What will be the effect of a blow of a heavy engine under such circumstances? A broken Rail! There seems to me no other way of accounting for the breakage of Rails on the Liverpool and Manchester Railway, than from this supposition. We know that the new 50 lbs. elliptical Rail is stronger in the middle than the parallel, and yet two of these have broken near the middle. This could not be produced by simple pressure. For in the same Rail, afterwards tested, the iron was bent nearly double without breaking. Is this not a proof of the existence of sudden shocks produced by the bounding of the engines? Why have so many Rails been broken in Olive Mount cutting? Because some of the Blocks are resting on the bare unyielding rock, whilst others are upon a thick layer of ballast, which after settling makes the undulations of the Rail more abrupt, and consequently the blows from the engines more effectual.

[To be continued.]

#### RAILROAD MEETING.

An Extract from the Proceedings of a Meeting held at Pekin, Niagara County, New-York.

At a meeting of the citizens of Pekin and vicinity, on the Northern Railroad route from Lockport to the Falls of Niagara, held July 18th, 1835, SILAS BELDING was called to the Chair, and JACOB COMPTON chosen Secretary.

A Committee was appointed to draft resolutions expressive of the sense of the meeting, and to communicate with the Directors of said road.

The following resolutions were adopted:

*Resolved*, That we view the location of the Railroad above named a subject of great vital importance to the inhabitants of the County of Niagara, to the travelling community, to the inhabitants of Lewiston and Pekin, villages situated contiguous to the northern route; also to the inhabitants of Upper Canada, so far as concerns the convenience of travelling, and to those that pass up and down Lake Ontario, arriving at any of the ports west on the Lake, Lewiston, Youngstown, Queenston, or Niagara, passing from thence east; and lastly, to the Stockholders in said Road, whose interests would be materially affected by the loss of

all the northern travel,—a circumstance inevitable, from the location of the south route.

*Resolved*, That in the opinion of the members of this meeting, the northern route would not lose any of the travel from Buffalo, as the distance does not materially differ in the two routes; and the connection with the "Buffalo and Falls Railroad" would be at the Falls, consequently the whole of the Lockport and Niagara Falls Company's road must be used by persons passing from Buffalo to Lockport, to or from; but should the south route be preferable, a junction of the two routes must take place at a point about six miles above the Falls, the two roads from thence running parallel to each other to the Falls. The consequence resulting from this would be, that persons passing from Lockport to Buffalo would leave the road at this point, and take the other and pass on to Buffalo, and vice versa; consequently, about six miles of the road would be left untravelled by all who had not sufficient curiosity to see the Falls to induce them to travel twelve miles of railroad, or business, amounting to the same thing: which class would constitute a large portion of the travellers passing over this road.

*Resolved*, That we consider that the business of said Road would be greatly increased by the construction of a Branch Railroad from the village of Lewiston to the nearest point on said Road, a distance of about one or two miles; and we are also of opinion, judging from existing feelings on the subject, that the inhabitants of Lewiston and Pekin would not hesitate, if a charter is obtained, to take the stock in said Branch Railroad.

*Resolved*, That we, the members of this meeting, hereby pledge ourselves, and this Committee also pledge themselves, to take stock in said Branch to the amount of five thousand dollars, for the village of Pekin, provided it is required for us to take that amount; that we feel assured that the stock in said Branch would be good, from the fact that Lewiston is the head of navigation on the American side of Lake Ontario, and destined to be a grand depot for all the commerce of the northern waters, and the point where all the northern travellers, and travel passing through Canada, to and from Michigan and Illinois, (which is very considerable during that part of the season when the Lakes are closed,) would embark in whatever conveyance was offered; and it ought also to be observed, that during the winter season, when all other ferries are closed, or impassable on account of floating ice, this affords a safe passage across the Niagara River, and this is the point where the great mail crosses, more particularly for this reason.

*Resolved*, That in the opinion of this Committee, should the Railroad be located on the south route, a line of stages would necessarily be kept from Lewiston to Lockport, a distance of about eighteen miles, where different lines are now running, and the roads thronged with stages daily. Lewiston is seven miles below the Niagara Falls, on the Niagara River, and seven miles above Fort Niagara, and is known to be a flourishing village,—the place where the steamboats of Lake Ontario land all their passengers, and receive those destined for the north.

The inhabitants on the Canada side of the Niagara River, in view of the prospect that our Railroad would be constructed on the south route, held a meeting on the subject of constructing a Railroad from Queenston to Chippewa, and determined to break ground within one month. Chippewa is about three miles above the Falls, on the Canada side; the travel would necessarily pass from thence to the places of embarkation on the Canada side of Lake Erie, if going west or south.

*Resolved*, That in view of the above considerations, and many more that might be presented, we are satisfied that the Directors of said Road ought to be informed on the subject, before they decide on the location. We do not ask that the gentlemen should take the assertions of persons interested, but examine the subject carefully for themselves.

The farmers and landholders on the northern route have nearly all signed off their lands, or given quit-claim deeds, for the benefit of the Company, so that no expense would accrue for lands of much amount. And who that has passed through Niagara County, does not know that the farms on the northern route, being those situated on the Mountain Ridge Road, are in a high state of cultivation? A good share of the ground over which the Road is laid is cleared, and the location the most beautiful for a Railroad that could be imagined, commanding an extensive view at an elevation of more than three hundred feet above Lake Ontario, of which, at many points, you have an extended view.

Presuming that the Directors are in possession of the surveys and estimate of the northern route, as made by the Company's Engineer, JOHN HOPKINS, Esq., and with these before them, they can at once be satisfied as to the difference of expense. But to know the difference of advantages, they should know the ground and country for themselves; after being acquainted with which, if gentlemen decide different from our views, we should rest satiated.

fed that we had done a duty we owed to our County, the place we represent, and to the Stockholders in said Road.

**RAILROAD CONVENTION.**—At a Convention composed of delegates from the several counties interested in the construction of the New York and Erie railroad, held at the village of Owego, on the 29th day of July, 1835, on motion of Stephen B. Leonard, Esq. G. McDowell was temporarily called to the chair, and Amasa Dana, appointed Secretary.

**Chataque**—Alvin Plumb, and Walter Smith.  
**Allegany**—John C. Cooley and George Stevens.  
**Steuben**—Ira Davenport, Levi Davis, Paul C. Cook, Benjamin Smead, William Kernan, Franklin Whitney, Z. A. Leland, Thomas A. Johnson and Thomas McBurney.

**Tompkins**—Ben Johnson, Amasa Dana, David D. Spencer, Minos McGoen, Henry Ackley, J. M. McCormick, John J. Speed, Jr. Francis A. Bloodgood, Samuel Love, E. G. Pelton, Augustus Sherill and Henry Ingersoll.

**Tioga**—James Pumpelly, George Fisher, John R. Drake, E. S. Sweet, Stephen Strong, Henry McCormick, S. B. Leonard, Jacob Willsey, G. H. Barstow, Elijah Shoemaker, George J. Pumpelly, Thomas Farrington, Charles Cook, Edward Quin, H. W. Jackson, N. T. Wynkoop and J. G. McDowell.

**Broom**—Martin Hawley, John A. Collier, Virgil Whitney, Mason Whiting, Jonathan Edwards, Joseph S. Bosworth, Wm. M. Waterman, James Hawley and Gideon Hotchkiss.

**Onondaga**—Gardner Tracy, Alvin Stewart, Horatio Seymour, Horace Butler, John H. Ostrom, A. G. Dauby, F. S. Faxton, Philip Thurber, James Sayre and Isaiah Tiffany.

**Chenango**—John C. Clark, Noah Ely, Augustus C. Welch, Caleb S. Butts, Samuel Medberry and Henry Calhoun.

**Otsego**—Charles C. Noble.

**Greene**—Jacob Haight.

**Orange**—Moses Webb, and Samuel J. Wilkin.

**Rockland**—J. G. Pierson.

**Cattaraugus**—James Brooks.

On motion of Mr. Collier, it was resolved, That a Committee, consisting of one member from each county, be appointed by the Chair, to nominate officers for this Convention. The following persons were appointed said committee, viz: Messrs. Tracy, Collier, J. M. McCormick, Welch, Farrington, Haight, Noble, Wilkin, Pierson, Smith, Kernan and Cooley.

The committee nominated WILLIAM KERNAN, of Steuben, as President.

Stephen B. Leonard, of Tioga,

Gardner Tracy, of Onondaga,

Walter Smith, of Chataque,

Augustus C. Welch, of Chenango,

Vice Presidents.

Amasa Dana, of Tompkins,

A. G. Dauby, of Onondaga,

Moses Webb, of Orange,

Secretaries.

The report was unanimously accepted by the Convention. On motion of J. C. Clark, Esq.

Resolved, That a committee of twelve be appointed by the President to report resolutions, expressive of the sentiments of this Convention, and that they report to-morrow morning at 9 o'clock. The following persons were appointed said Committee, viz: Messrs. Clark, Dauby, Cooley, Leland, Farrington, Wilkin, B. Johnson, Collier, Noble, Haight, Pierson, Plumb. Adjourned to 9 o'clock to-morrow morning.

JULY 30th, 1835.

The Convention met pursuant to adjournment.

Mr. Clark, from the committee on resolutions, presented the following, which were unanimously adopted:

Resolved, That we are in favor of a large and liberal system of internal improvements, and being deeply impressed with the great and increasing importance of multiplying facilities of communication between different sections of the state, and of opening convenient channels of intercourse between those states already connected, or which may be connected with us in their business relations by works of internal improvement, and by none, it is believed, can this important object be more advantageously accomplished than by the contemplated Railroad from New York to Lake Erie. Therefore,

Resolved, That reposing as we do confidence in the representations of the Company empowered to accomplish this great and interesting work, we

earnestly recommend to the legislature of this State, having satisfied itself of the practicability of the measure, to extend its aid for its completion, by loaning its credit, under proper limitations and restrictions, for such sums as may be considered necessary, upon its receiving such guarantees of security for the same as shall be deemed sufficient to protect the State from loss or injury.

Resolved, That in the opinion of this convention the system which has been adopted and so far prosecuted with great success for the development of the resources and improvements of the condition of this State by the construction of canals and railroads, should be encouraged and persevered in, until the advantages are extended to every part of the State susceptible of such improvement—that to this policy this State is greatly indebted for its present highly prosperous condition, and that the gigantic efforts now making by her southern neighbors to direct the trade of the entire western States from this State into other channels and other regions, call for increased and steady efforts to secure to the citizens of this State a fair and permanent participation in the advantages of that trade.

Resolved, That we deem it hardly necessary to express what would seem to be a sentiment of obvious justice and propriety, to wit: that no work of the character referred to, whether sought to be accomplished by individual means and individual enterprise, or by the resources of the State, should meet with hostility and opposition on local, sectional or party grounds, but should stand or fall on a just view of its merits, and of what is required to promote the interest and prosperity of the country, —therefore

Resolved, That while we claim to be actuated by a spirit of enlarged and liberal state policy, in recommending to the favorable consideration of its citizens the New York and Erie Railroad, we feel the utmost confidence in the justice, liberality and patriotism of those not perhaps so directly interested in the construction of this work as the constituents of the members of this convention are, and rely upon their generous and efficient support—thereby securing to the State, beyond the hazard of future contingency, the incalculable benefits of possessing the cheapest and most expeditious communication by which the immense and rapidly augmenting products of the west, can be transported to market.

Resolved, That this Convention will unite and co-operate with its friends in the counties of Columbia, Greene, Schoharie and Otsego, in such suitable measures as they may adopt to promote a communication by Railroad from the eastern bounds of Columbia county to Lake Erie Railroad, in the valley of the Susquehanna.

Resolved, That it be recommended to each county and town interested in these projects to appoint committees to obtain signatures to petitions to the Legislature in furtherance of the object in view.

Resolved, That this Convention, reposing full confidence in the company's intention to immediately commence the work, giving sure pledges of its speedy completion, therefore recommend to the citizens of the several counties for whom stock has been reserved to subscribe for the same.

Resolved, That the Board of Directors are respectfully requested by this Convention to extend, if consistent with their arrangements, the time for closing their subscription books in the counties on the line of the road, until the first of October next.

The following resolution, passed by the Board of Directors of the New York and Erie Railroad Company, on the 22d July, ult. was read by a member of the Convention:

Resolved, That this Company will wholly abstain from speculating in or purchasing any lands whatever on the line of their Railroad, (except such as may be requisite for the convenient accommodation of their concerns,) and that they will not, even for those purposes, purchase any lands without previously declaring to the owners thereof, that the application is made in behalf of the Company.

Whereupon it was unanimously

Resolved, That we highly approve of the resolution of the Directors of the Railroad Company, pledging themselves to abstain from the purchase of real estate on the route; that by foregoing the speculations which their knowledge on the subject would enable them to make, they give to the people an earnest of their public spirit, manifesting sentiments and feelings honorable to themselves and worthy the great measure in which they are engaged.

Resolved, That the following persons be a central Corresponding Committee, viz: James Pumpelly, Jedediah Fay, E. S. Sweet, Thomas Maxwell, G. H. Barstow, John A. Collier, Thomas Farrington, Stephen B. Leonard, Stephen Strong.

Resolved, That the cordial thanks of this Convention be returned to its officers for the dignified, able and impartial manner in which they have discharged the duties imposed upon them.

Resolved, That the proceedings of this Convention be signed by its officers and published.

WILLIAM KERNAN, President.

S. B. LEONARD,  
GARDNER TRACY, } Vice Presi-  
WALTER SMITH, } dents.  
A. C. WELCH,

AMASA DANA,  
A. G. DAUBY, } Secretaries.  
MOSES WEBB,

**BALLOONS SUSCEPTIBLE OF DIRECTION.**—The following article is curious, and of much promise.

[Translated for the New York American from the Prussian State Gazette of 19th May.]

BRUNSWICK, the 11th May.—Much sensation is here created by the experiments of Dr. Weinhoff, with air-carriages, whose movement, direction, and stopping, are entirely in his power by a simple contrivance invented by him. The consequences of such an invention, hitherto concealed even to the most searching ingenuity, are immeasurable, and will, in case of success, overthrow many of the now existing relations in commerce, in the military system, nay, in almost all social connexions, and substitute new ones. What enlargements and improvements will be derived from that invention for science, apart from its practical utility, no part of the earth being unattainable or inaccessible to an air-vehicle, and the passage through the air, in itself always the straightest way, never, and nowhere, being subject to any obstruction. Though the experiments tried by the inventor, are but made on a small scale, yet the principles upon which they are founded are so evident, and the contrivances so simple, that their practicability, on a larger scale, and in the actual application, can no longer be doubted. It is gratifying to see the pleasure which the plain, simple man, far from all ostentation, and full of inspiration for his invention, takes in communicating it to others, without concealing anything. To render his secret a common good, he has determined to make it as public as possible by the press, so that in a few days, the book will lie open for examination; and it is to be expected, from the firm conviction, and the decided sincerity of the inventor, in regard to his experiments and their explanation, that it will open for itself the path which it deserves. The book is to be published here, in Brunswick, by Schure & Muelles, under the title of "Lufschiffahrt und Maschineneisen," (the navigation of the air and the system of machinery,) by Dr. Wm. Weinhoff. It purports to contain the proof of a new process applied to the movement of machines, carriages, shooting-engines, and projectiles of all kinds, more powerful and advantageous than any hitherto used, and of the greatest importance, because it places at our command, the horizontal direction of the air-balloon, and the aerostatic vehicle, as well as the movement, stopping, and directing of air-vehicles, without any aerostatic aid, in horizontal and vertical directions.

[From the Chicago American of Aug. 1st.]

Our town, we are happy to say, is very healthy at present, although the changes of weather have been great, varying in some instances, ten, fifteen, twenty, and sometimes more, degrees in twenty-four hours. So far as we can learn, there have been but three deaths in about as many weeks, two of which were violent—murder and suicide. We make this statement to correct the numerous false reports which are circulating in different parts of the east, and which have no doubt been put in circulation by designing persons, to stop the tide of emigration which is now fast filling up this fertile country. So far as we have been able to ascertain, (and we have taken considerable pains to learn) the whole country is now enjoying, in an eminent degree, that greatest of all blessings—health. It is true that the cholera did exist for a few days in some of the towns on the Illinois River, approaching at one time within about 80 miles of us; but it entirely disappeared some weeks since. To emigrants we would say, "come on." We pledge them a hearty welcome, and fair and goodly land—fertile as the banks of the Nile.

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, AUGUST 29, 1835.

**EVERY'S ROTARY ENGINE.**—After a long and vexatious, and yet unavoidable delay, we are enabled to give a drawing of Avery's Rotary Engine, of which we have frequently spoken before. The annexed drawing is taken from a two-horse power engine, built for this office, to drive a printing machine, which prints both sides of the sheet before it leaves the press. This engine, as it will be seen, together with the boiler, force pump, and governor, and, in short, *every thing necessary* for communicating motion to them and to the machinery to be operated, occupies a very small space, it being only 4 feet 8, by 2 feet 10 inches. The boiler is 17 inches in diameter, and 78 inches high; the furnace for anthracite coal occupying about one fifth part of it.

The principal advantages of this engine, as we conceive, consists in its compactness, the ease with which it is managed by any person who can tend the fire, the trifling cost of fuel, as well as the small outlay for the engine. The most important advantage, however, for many purposes, and especially for driving *printing machines*, will be found in its perfectly uniform motion. It is indeed so perfect, and the velocity so great, being about *five thousand* revolutions of the arm, shaft, and of course pulley on which the band runs, per minute, that but for other than the ordinary machinery attached to

the engine, a casual observer would scarcely know that a steam engine was in operation.

In No. 12, vol. iv., of the Railroad Journal, is published an account of the performance of an engine used by the proprietors, Messrs. E. Lynds & Son, in their shop at Syracuse, New-York, which has now been in use more than two years, and we cannot do better than to re-publish a part of that article.

The following extract refers to an engine with 18 inch arms, of 6 horse power, but the engraving given herewith represents one with 12 inch arms, or about 2 horse power. There is one now in operation in this city for sawing mahogany, with  $2\frac{1}{4}$  feet arms, which will do the work of a 12 or 15 horse power engine, and performs to the entire satisfaction of those who use it.

"The engine, that is, the shaft and arms, weigh, as I learn, only 15 lbs.; the arms, from centre of shaft to their ends, are 18 inches, and in their revolutions describe a circle of 9 feet 5 inches in circumference; the two apertures at the end of the arms are equal to the eighth part of a superficial inch, and under a pressure of 80 lbs. to the square inch, will balance a weight of 10 lbs. From some experiments made, it is estimated to carry a load of 8 lbs. through a space of 37,866 feet per minute. The boiler has 66 feet surface exposed to the fire, and consumes daily half a cord of soft dry wood.

There are in the establishment the following machines in operation, namely, 2 large engine lathes; 2 small do. do.; 2 hand lathes; 1 boring mill for boring cylinders; 2 drilling lathes; 1 grindstone; 1 mill for grinding coal; 2 bellows, 40 double strokes each per minute, which will force 580 cubic feet of air per minute, under a pressure of  $1\frac{1}{2}$  lbs. per square inch, and requires 4 to 5 horse power to perform its operation of melting 1500 lbs. of iron per hour."

The following references will give an idea of the engine; to examine it, however, will be more satisfactory.

A, the boiler, 17 inches in diameter, and 78 inches high, standing on a cast iron frame, with a grate inside.

B, the steam pipe, which conducts the steam to the end of the shaft C C, one end of which is enclosed in a superfluous cast iron tube. The steam is ordinarily conducted from the boiler to the end of the shaft in a simple steam pipe, which may be six inches, or 6 or 12 feet in length, to accommodate the engine to the machinery, without regard to the position of the boiler.

C C, the shaft passing through the case D, and the arms Q, Q, fig. 2, which are enclosed, and revolve in the case D. On this shaft, as will be seen in fig. 2, is the pulley E, from which the band passes to the machinery.

D, a circular cast iron case, in two parts, fitted and put together with bolts, and made steam tight. This case has in some instances been made of sheet iron; cast iron, however, is deemed best. The case, although the engine, or revolving arm, is only  $\frac{1}{2}$  of an inch in the thickest part, is at least 5 inches through in the centre, where the shaft passes, having the two concave

Fig. 2.

surfaces turned together; and it is considerably larger, or of greater diameter, than the length of the arms, that there may be space, which is enlarged by giving to the casting, near the outer edge, a half circle in each part of about 3 inches in diameter, which forms a circular channel or groove for the steam beyond the end of the arm, and by which it finds the outlet F, through the bottom, and connected with a pipe which conducts it off outside of the building.

G, the supply pump, operated in this engine by cog wheels, but ordinarily by a band. The wheels, however, are not represented in the engraving, being desirous to show the engine as in general use, and simplest form.

H, I, the governor, or apparatus for regulating the supply of steam to the engine. This regulator is constructed upon a new plan, and works with cog wheels.

K, gauge cocks.

L, safety valve, which is set at a pressure of 100 lbs. to the square inch.

M, smoke pipe—a six inch stove pipe.

N, apparatus for stopping the steam, or letting it on to the engine.

O, serves to regulate the packing around the shaft.

P, water supply pipe.

Fig. 2.—C C, shaft; E, pulley for the band; r, the orifice in the end of shaft where the steam enters; Q Q, the arms at right angles with the shaft, and through which it passes.

There being a free communication (except when obstructed by the throttle valve, by which it may be in part, or entirely cut off, as may be desired, thereby increasing or diminishing the velocity,) from the boiler to the shaft and arms, there is necessarily an equal pressure upon the square inch of the arms, as upon the boiler, and hence the reaction, in consequence of the pressure in every part, except where the steam escapes, and not from the action of the steam against the atmosphere, as is generally supposed.

This engine, we are yet fully in the faith to believe, will be found an important improvement for railroad purposes. The only locomotive engine of the kind ever used, run

for a short time, last spring, on the Newark railroad; and, after various experiments, which were made to test its qualities and power, a car was loaded with four tons of iron, and attached to the engine, which took it, with great ease, over the Bergen Ridge, where there is an elevation of 152 feet to the mile—and in one place, for a short distance, when leaving the direct track for that built temporarily on the bank, of six feet in one hundred, or 312 feet to the mile.

This performance, although in itself a small affair, is, knowing, as we do, the ingenuity and perseverance of the inventor, William Avery, to us evidence that another engine, built and improved upon by the little experience already had, will surmount elevations of 150 to 200 feet per mile, with loads of eight to twelve tons, and that the same engine will, on a level, or gently undulating road, perform 35 to 50 miles per hour.

Mr. Avery is now engaged upon a locomotive engine, a model of which we have examined, which will, we doubt not, perform all we have here predicted; and if so, what can prevent them from being generally adopted on all our Railroads?

If we were at liberty, we should attempt to give a drawing and description of this locomotive; but, as it is his desire to complete it first, we shall defer for the present further allusion to it, or until we have permission to give a definite account of it.

[From the London Mechanic's Magazine.]

ADAMS' CIRCULAR SPRING WHEELS.

"Break all the spokes, \* \* \* \*  
And bow the round nave down."

It has long been a desideratum amongst mechanicians, to accomplish the task of constructing a wheel for carriages intended to convey persons and goods over rough roads, which, while it should possess sufficient strength fully disposed in its several parts to resist breakage, unsteadiness, or any permanent alteration of form, from any of the ordinary shocks or violence to which it might be subjected, should yet possess the property of elasticity to such a degree, as to intercept and materially diminish the concussion caused by the periphery rolling over obstacles during its revolution; and thus either prevent the concussion from extending its effects to the axis round which the wheel might revolve, or to lessen it so much that the effects might be comparatively innocuous. It must, of course, be necessary that the elastic power should be placed between the periphery and the axis, without in any way diminishing the roundness or altering the circular form of the periphery—which circumstance would tend materially to increase the rolling friction of the wheel: wherefore the only mode in which elasticity can be made available, must be by enabling the axis to depart sufficiently from the exact centre of the periphery where concussion takes place—to which

exact centre the elastic force, pressing equally in various opposite directions in the plane of the wheel, should have a constant tendency to restore it when the effect of the concussion might cease. The advantages attendant upon a wheel so constructed are several and obvious.

1st, In ordinary sized wheels, used for a cart without springs, the concussion from the road is driven in a direct line along the spokes of the axis; and this concussion, constantly kept up as the wheel revolves, serves materially to increase the weight of draught, by forcing out the oil or grease, and bringing the rubbing surfaces of the axis and axis-box in close contact, to the increase of friction. This disadvantage would be removed entirely, or very materially lessened, by the use of an elastic wheel.

2d, In carriages with rigid wheels, to which the axis is attached by means of a horizontal spring bearing on the axis, the concussion is diminished, by its uniform bearing upwards; still it is but slightly, inasmuch as the momentum of the concussion passes directly along the rigid spokes to the axis; and, moreover, the relief which the spring affords is only in a vertical direction; in which direction the greatest amount of the momentum of concussion does not pass, but in a direction more inclining towards the line of progress as the wheel revolves. This disadvantage would be materially lessened by an efficient elastic wheel, inasmuch as the elasticity being in a circle all round the axis, would avail both against vertical and horizontal obstacles or inequalities.

3d, It is well known that the force requisite to move a carriage at first starting is greater than that required to keep motion up. The reason of this is, that momentum is required in proportion to the rapidity of the motion. Wherefore, every obstacle or inequality which the wheel encounters as it revolves, has a tendency to check the momentum, and render the draught power necessary to move the carriage onwards nearer in amount to that which was originally required to move it from a state of rest; because the concussion in the line of progress is nearly in direct opposition to the momentum, and serves to neutralize it. An efficient elastic wheel would be found to receive the concussion on its periphery, but as it would not carry it, or would carry it with a diminished force, to the axis, the momentum of the superincumbent framework, to which the draught power is attached, would scarcely be acted on by it.

4th, The wheels of carriages are subject to considerable concussion in a lateral direction, lengthwise of the axis. A rigid wheel, under such concussion, transmits the concussion almost unbroken to the carriage, to the annoyance of the passengers, and with a tendency to derange the framework. But an efficient elastic wheel would possess a small portion of lateral elasticity, sufficient to diminish the violence of the concussion, and yield greater ease of motion.

5th, An elastic wheel, by its tendency

to elude concussion rather than to resist it, will be less liable to be broken or strained than one which is rigid, and consequently its total durability is likely to be much greater. Wooden wheels, by reason of their property of elasticity, are less liable to break than those of iron.

Wheels are to a carriage what legs are to a human being—the instruments of locomotion. A man who loses an elastic leg, of bone, muscle, and ligaments, may have a wooden one to replace it; but he will find that the act of walking with the wooden one is a much ruder and less perfect process than with the one of bone and muscle; concussion, and the labor of surmounting or avoiding obstacles, will render the man's progress much slower. And it seems clear, that the property of elasticity in a wheel gives it a similar advantage over a rigid one that the natural leg does over the artificial one, though to a less extent; inasmuch as the mechanical contrivance of art must be inferior to the more perfect processes of nature. Ships, which are of rigid construction, are found to make a slower progress through the water than such as are slightly flexible; and in row-boats, the quality of flexibility is indispensable to swiftness: the reason is, that the flexible boat, as it advances, adapts itself, by its sinuosity, to the slight movements and currents of the water, which it eludes instead of resisting. The movement of a fish through the water is an illustration of the same principle; and, by a parity of reasoning, a carriage with elastic wheels avoids, by its yielding properties, many obstacles over which rigid wheels would require to be impelled by a greater exertion of power.

The general conviction of the advantages to be obtained by using elastic wheels has led to many attempts at their construction, but hitherto without any efficient result. One mode which was attempted was by arranging a number of pointed double elliptic steel springs in radiating lines from a nave to a periphery. To guard against the lateral action or leverage, these springs were doubled in number, and arranged at a lateral angle with the length of the nave each way. Even supposing such a wheel to be efficient, the expense of its manufacture would have precluded any extensive use of it; but the action was too imperfect, to allow much use without destruction of its parts. The elasticity of the springs could only be brought into action in the direction of the length of the ellipses, either by extension or compression; consequently the action could only be in a line diametrically across the wheel in one direction at a time: thus but few of the springs would be in action at one time, and that in a most imperfect mode, viz., in the length of a very long and narrow ellipse. The principle of an efficient spring wheel should be, that the elasticity should be alike at all parts of the circumference, and that no one part should act without the whole—that every spring should sympathise equally with the rest, from whatever direction a concussion

might come. A wheel like that just described could not comply with this condition, and therefore such a wheel could not be durable. Another mode of forming a spring wheel was by making steel blades or ribbands in a sinuous or undulating curve, and forming them in radiating lines from a nave to a periphery, doubling them in the same manner as described in the elliptic spring wheel, to resist the lateral action or leverage. Supposing this wheel to be true and well made, the action would be more perfect than the former one; but the making of such springs all to stand their work equally well, and the needful accuracy of fixing them, would involve an expense too great for any extensive use; and after all, the action would be of that kind very likely to break the springs with a violent concussion. A third plan which has been proposed, but, we believe, never put in practice, is a small wheel placed within the circumference of a solid rigid ring of much larger diameter, the space between being supplied with several small hoops of ribband steel with open ends, put in with compression, so as to leave them free to enlarge or diminish their diameter when in action. These hoops were to be kept in their places by flanged segmental cavities adapted to their size in both wheel and ring, being otherwise unconfined by any fastening. The disadvantages of this form of wheel are many. First, its extreme want of elastic firmness; next, its want of universal action, being calculated only to act by compression on the springs below, and not by extension of the springs above. A great defect would be, that while the weight were pressing on the lower springs, the elastic action of the upper springs would be directed, not to alleviate, but to increase the weight. In action, this wheel would be impracticable; for stones and dirt would lodge in the centres with the springs, clog their action, and break them. But one useful thing they contain, viz., the germ of the only sort of spring which can be effectively applied to spring-wheels—the circle. The wheel itself is a circle continually revolving, and springs intended to have an equal action in that wheel, whatever side be uppermost, must be circles likewise. No other form can be of universal action, in the place of the wheel; no other form will yield extensibility and compressibility in every direction in rapid succession, each tending alike to restore the nave to the exact centre of the periphery, as the momentary action of concussion passes away.

Mr. William Adams, a partner in the firm of Hobson and Co., of Long-acre, has marked this essential principle, and has had the perseverance to work it out in detail, so as to lay it before the public in a practicable form. The leading features of his invention are four hoops of broad steel plate, properly tempered, the ends of the hoops being overlapped and rivetted together, so that each hoop may be solid, by which means it will resist and yield equally, both by extension and compression. These hoops

are affixed firmly at equal distances in the interior of a rigid circular rim, which forms the periphery of the wheel. This circular rim is made rigid by its peculiar mode of construction. An inner iron, or steel tire, of less substance than the outer one, is surrounded by a circle of wooden felloes, accurately fitted to the inner tire, and also with their ends accurately fitted to each other like a barrel arch, the lines of the joints meeting in the centre of the circle. Around this circle of felloes, so fitted, the outer tire is shrunk on hot, as usual, and all three thicknesses are rivetted together. In calling this a rigid rim, we do not mean that it is rigid like an iron casting, (for if it were so, it would not stand its work, but be liable to break, as cast iron wheels do;) but that, while it possesses a slight portion of elasticity sufficient to prevent breakage, it is also sufficiently strong to prevent any permanent alteration of its form by any ordinary concussion to which it may be subjected. To this rim the four hoop springs are firmly bolted, but do not in any material manner contribute to strengthen it. The springs serve as elastic legs; the rim serves as a foot to guide the steps they make in revolving. Wheelwrights call the act of putting a tire on a wheel, "shoeing it."

The nave of this wheel is made of iron flange plates, fitted to the axis-box, and reinforced by wood blockings. The flange plates are made in the form of a Maltese cross, and to the arms of this cross the hoop springs are firmly fixed, each with four clip bolts and nuts, without making holes in the spring; and this mode is found to ensure sufficient lateral strength to resist the central leverage of the wheel. The springs are tapered in width towards the circumference, in order to give the greatest elasticity towards the point of concussion. The axis-box is so contrived that it will carry a very large magazine of oil in actual contact with the axis, and the wheel is therefore likely to travel considerably farther without requiring fresh oil than any other kind, more especially as the elastic action removes the extra friction arising from concussion. Most oil axes are fed with oil by a capillary or pumping action. This action is liable to be disturbed from many causes, and if disturbed, the wheel will become fast on the axis by heating. But an axis in actual contact with the oil cannot be liable to these accidents.

One of the first considerations which struck us was, that a wheel with so much metal in it must necessarily be very heavy; but this proves not to be the fact. The peculiar action and combination of the springs being such that all mutually assist and are dependent on each other, the thickness of the plates is necessarily so much reduced below the ordinary standard of spring plates, that great lightness is combined with great strength. Thus a pair of these spring wheels are found to be just so much heavier than ordinary wooden ones as the weight of the inner tire amounts to. But as the axes used in ordinary rigid wheels are made much

Fig. 2.

carriages with hout, on rail- one-half. The carriages are play, and that ich is not the pid speed, the eases in com- speed used on age to pieces all pebble, or point of a rail, violent shock, sh succeeding carriages, like a hammer, at weakness of a breaks it, or e elasticity of direct line of und carriages and the total erably dimin- id wheels used sionally a ten- in an exactly of the flange at the rail, and . It seems to ticity of Mr. e a tendency ident; for the rigid plane, n the rail, as might give it a lateral elastic restore the proper posi-

es another ad- n case of the icident to all of roundness, A rigid wheel

of this form must necessarily move with much friction; but the elasticity of a spring-wheel would tend to correct this defect, by yielding where there was the necessity during its revolution.

For ordinary weights, the springs are made in single plates, by which means they may be effectually preserved from rust; but for heavy carriages and engines, the inventor proposes to multiply the number of plates in the same mode as other carriage springs.

Fig. 1 is a side elevation of the wheel. Fig. 2 is the cross section. A is the outer tire; B, the felloes; C, the inner tire; D, blocks to bend the springs on the rim; e, the clips to fix the blocks down the springs on the rim; F, the central Maltese cross and axis-box; g, the circular springs.

By the simplicity of construction, if a spring should break, it may be removed and re-placed, without taking a carriage off the road, in a few minutes. The railroad central nave is of still simpler construction than that for the common road.

[From the London Mechanics' Magazine.]

**Bernhardt's Patent Warming and Ventilating Process.**

Several indistinct notices have appeared in the newspaper press, both domestic and foreign, during the last twelve months, (and some, it must be confessed, of rather a high-colored description,) of a new mode of warming and ventilating, stated to have been discovered by Mr. Bernhardt, a Saxon architect of considerable eminence, and exemplified by him with extraordinary success in a number of public buildings on the continent. As Mr. Bernhardt has taken out a patent in this country for his invention, and the time for his specification has now nearly expired, we shall soon be enabled to lay the whole particulars of his plan before our readers; but, in the mean while, the following extracts from a statement authenticated by the signature of Professor Schaeffer, of Dusseldorf, may be accepted as good evidence that Mr. Bernhardt has actually arrived at some results of more than ordinary importance—one of which, at least, is, even in this country of high mechanical invention, still a great desideratum, namely, *smoke without soot*. A late distinguished physician (Sir George Tuthill) has left it on record as his deliberate opinion, that the excessive quantity of carbonaceous matter sent forth into the atmosphere of London from its innumerable coal fires is the grand cause of its unhealthiness, as compared with places in its near vicinity.

"The Royal General Post-Office built, many years ago, a factory adjoining the post-house, for the repair of the mail-coaches, and since the building of the diligences and the increase of business, it has become a very large coach manufactory, in which above seventy workmen are at present daily employed. In a building at the back, arranged for the purpose, a forge for ten fires was put up and erected in the usual form. Smoke

and soot penetrated into the dwellings of the neighbors, and rendered them uninhabitable and worth no rent. Complaints arose, and an expensive law-suit, which naturally terminated to the disadvantage of the Post-Office department. Experiments were then made to clarify the smoke and separate the soot. The Prussian consul in England—that land of invention—was desired to make inquiries whether any means were known to remedy the evil, but nothing could be done; and the most learned professional men doubted the possibility of an invention to answer the purpose, because it was believed that any attempt to separate the smoke from the soot could only be made at the expense of the draught.

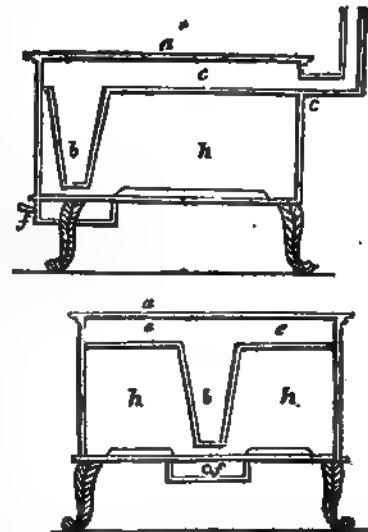

"It became a point of consequence, to the Post-Office authorities here, to satisfy the neighbors at any price, and they endeavored to suppress the nuisance arising from the soot by removing the smithy into an intermediate building constructed for the purpose: the result of experiments by several artists, in inventing an apparatus by means of which it was hoped to banish the soot. A cistern of water was applied over the roof, which was intended, by being placed round the outlet for the smoke, to absorb its heavier parts; but the soot soon covered the water with an incrustation, and the finer particles of the soot escaped from the chimney and covered the gardens of the neighbors; besides the smoke spread itself throughout the smithies, so as to be dangerous and insupportable to the workmen at the fires. At that time the architect, Mr. Bernhardt, of Saxony, was in Berlin, and had been employed in the Royal Palaces; having devoted the whole of his life to the study of the deficiencies at present existing in the construction of fires, he was enabled to correct the similar faults in the General Post-office buildings, and his plans were crowned with the best success. Mr. Bernhardt discovered the means of forcing the draft of the smoke, and separating the soot from it. His plans were carried into execution. In a short time, without any interruption to the business of the coach factory, the work was completed. The smoke ascends in a purified state through two cylinders of zinc to the roof, and the soot remains in the interior of the three story high building, concentrated in separate channels and chambers for it.

"It is remarkable to observe the soot depositing itself in coarse particles, and afterwards becoming gradually finer as it ascends; to see the smoke rising through narrow wire nets. In the channels of the five chimneys a mass of 26½ cubic feet of soot was found, after three months' purifying, and which had formerly been mostly conducted over the roof."

**THE BRUGES STOVE**, as improved by Messrs. Cottam and Hallen. By Mr. Edward Cottam.—I send you sketches (figs. 1, 2, 3,) of the Bruges stove, as manufactured by Cottam and Hallen, who have found it to answer fully the statement given by them of it in your Encyclopedia of Architecture. It will do more with a given

quantity of fuel than any other stove, having the means of stewing, boiling, broiling, roasting, and baking, at one and the same time, with a small quantity of coke or cinders from any other fire.

It is simple in form, and there is not the slightest difficulty in its use. The holes in the top may be arranged as is found most convenient for the situation in which the stove is to be placed, either in a line, as in the sketch, (fig. 1,) or in the form of a triangle. One thing is indispensable for the proper action of this stove, and that is a good draught. It must, therefore, have a separate flue.

In figs. 1, 2, 3, a is the top of the stove; b is the fire pot; g is the hole for feeding the fire pot; f is an ash drawer; c is the flue; D is the oven door; h is the oven; e is a space for the fire to pass to the flue c, and for heating the whole of the top plate, any part of which will produce sufficient heat for culinary purposes; i i i are lids, which may be taken off, and the battery of stew-pans, or boilers, will then be in contact with the flame. A grid-iron fits on any of these openings, which has the advantage of not smoking the article broiled, the draught being downwards.—[Loud. Arch. Mag.]

**THE WESTERN RAILROAD.**—Books of subscription to the stock in the Western Railroad Corporation were opened in this city on the 3d inst. and will be closed to-morrow. The amount of capital proposed to be raised is 20,000 shares, of \$100 each. On the day of the opening of the books over 7000 shares were subscribed in this city, and about 1900 have been subscribed here since. We learn that about 1500 shares had been subscribed last week in Springfield, and 300 in New York. Of the amount subscribed at the other places where books were opened, we have no accurate information.

The receipts on the Boston and Worcester Railroad, for the week ending the 1st inst. were for passengers, \$2903 37; for freight, \$503 49; total, \$3705 86. For the last week, for passengers, \$3897 58; for freight, \$384 51; total, \$4282 09. [Boston Daily Adv.]

**THE PORTLAND AND QUEBEC RAILROAD.**—In the New Hampshire Patriot we find a letter from Col. Long, who has been employed in making an examination of the route for a Railroad from Portland to Quebec, addressed to the Hon. Isaac Hill, in which he states some interesting facts relative to this route. From these facts it appears that the route, although by no means impracticable, presents obstacles of a serious character, and more formidable probably than were anticipated by the friends of the enterprise. Col. Long left Portland on the 6th July, accompanied by Charles Fox, Esq., agent for the city of Portland, and proceeded northwardly about 77 miles, to Andover, the most remote settlement on the route. The ground thus far is mostly favorable. Here they entered the wilderness, and proceeding in the same direction, found an ascent to be encountered, of about 500 feet in a distance of six miles. They there entered the lake country, which they approached without making any descent. The residue of the route is thus described:

"We first struck upon Lake Allegundebagog, then upon Lake Molechunkemaunk, both of which are on the same level or very nearly so. Having crossed these lakes, we passed a very flat ridge dividing between the lake last mentioned, and Mooslamaguntic Lake, the latter being elevated about 30 feet above the former. We proceeded thence into Lake Cupmetuc, on the same level, and ascended thence in the valley and vicinity of Cupmetuc stream, to the summit dividing between the waters of the Atlantic and those that fall into the St. Lawrence. In the ascent of this stream, an elevation of at least 500 hundred feet is to be overcome, which may be effected, at a gradation no where exceeding one degree. Having reached the summit, on which we crossed the boundary line dividing between the United States and Lower Canada, we soon struck the Arnold river, which rises in the same swampy tract that gives birth to the Cupmetuc stream, the distance from water to water not exceeding half a mile, and commenced our descent in the valley of the river just mentioned, viz. Arnold's river, and travelled downward about 16 miles to Lake Megantic, the descent for a distance of ten miles being such as to require a gradation of one degree. We then proceeded downward along the Lake and in the valley of Chaudiere river, 60 miles, to the upper settlements on the river last mentioned, the declivity after leaving the Lake, being on an average of about 10 feet per mile. Through the entire distance from Lake Allegundebagog, to the upper settlements on the Chaudiere, we had to grouse our way through a trackless wilderness, encountering thickets, swamps, windfalls, &c., the distance being about 120 miles. We then proceeded down the Chaudiere 66 miles, in view of one of the most beautiful countries I ever beheld, to this city, the entire distance from Portland to Quebec, by the route pursued, being about 275 miles, which is some 8 or 10 miles shorter than the nearest travelled road.—The elevation of the main summit above tide, agreeably to the best observations I have been able to make without the aid of instruments, is 15 to 1700 feet."

The project appears to have been very favorably entertained at Quebec, as we infer from the notices of it in the Quebec papers, and Captain Yule, of the Royal Engineers, was appointed by the Governor in Chief to accompany Col. Long.

[From the Troy Whig.]

**RENSSELAER AND SARATOGA RAILROAD.**—That portion of this important Railroad extending from the village of Waterford to Ballston Spa having been completed, the event was celebrated yesterday by the company with appropriate public ceremonies. The President and Directors of the Company, with the Common Council of the city of Troy and a large party of gentlemen, escorted by the Albany Republican Artillery commanded by Capt. Strain and by Capt. Erckenbrack's Company of Artillery from this city—all under the command of Colonel Cortland Schuyler, as Marshal, assembled at an early hour on the east bank of the Hudson River, near the Waterford Bridge. A procession was then formed, and with the accompaniment of a fine band of music, proceeded

across the Bridge where it was met by the civil authorities and citizens of Waterford and was conducted to the Mansion House of that village.—Soon after the procession moved from the Mansion House to the Railroad depot, where a locomotive, to which was attached a train of elegant new Cars, was in readiness to receive the company. The party left Waterford about half past eleven o'clock amidst the loud and long continued cheers of an immense crowd of spectators.

At Ballston the party was met by the military and citizens of the village and neighborhood, and escorted to the Sans Souci Hotel, and the whole company sat down to a sumptuous dinner provided for the occasion by Mr. Waters. The festivities of the table passed off with great spirit and hilarity. The good feeling, cordiality, and hospitality with which the party was received at Ballston, have been spoken of by all the gentlemen with whom we have conversed on the subject, in the highest terms of commendation. On the arrival and departure of the cars, salutes were fired from a field piece placed on the high ground overlooking the village.

The cars left Ballston on their return at half past four o'clock, and in consequence of an accident, which caused a detention of several hours on the road, did not arrive at Waterford until a late hour in the evening. This circumstance somewhat interrupted the pleasure of the excursion; but we are happy to state that no serious injury was done either to the persons in the cars or to the locomotive. The cars continue their regular trips to-day.

We congratulate the Directors of the Rensselaer and Saratoga Railroad upon the success which has thus far attended their exertions in prosecuting this Road to its completion. The remaining portion of the Road between the city of Troy and Waterford, is in such a state of forwardness as to warrant us in stating that the period is not far distant when it will be ready for the passage of cars. We congratulate also the travelling public upon the increased facilities which the opening of this Road will furnish them in visiting Ballston and Saratoga.

[From the Dayton (Ohio) Journal of Aug. 11.]

**RAILROAD FROM DAYTON TO LAKE ERIE.**—The Prospect Ahead!—By the advertisement of the Chief Engineer upon the Mad-river and Lake Erie Railroad, inserted to-day, it will be seen that 35 miles of the work will be put under contract on the 17th of September. This is going to work in earnest, and makes the construction of the road certain if it ever was doubtful. The further the examination has been extended into the advantages which will result from it, the more convincing is the evidence that its importance has been underrated—and that it will agreeably disappoint the expectations of those most sanguine of its future usefulness.—At a recent meeting of the Directors held at Bellefontaine, Mr. Bell the Engineer upon the line, communicated information relative to the survey highly important to the board, and interesting to the whole section through which the road passes.—He speaks of the country so far as his survey has extended, as being admirably calculated for the contemplated route, and his estimates of the expense are considerably below those originally made by Mr. Stansberry, the U. S. Engineer. From Sandusky to Tiffin, 35 miles, his estimate of the cost for grubbing and clearing for a double track and completing a single track is \$200,800, being an average of less than \$7000 per mile. Mr. Stansberry's we believe was but a fraction below \$19,000. And it is probable, that Mr. Bell's estimates, upon the whole route, will show an equal reduction with those of the first 35 miles, upon the original estimates of Mr. Stansberry. This is an important item for the stockholders, and we understand it has inspired the Board of Directors with a new incentive to make a commencement at Dayton. We hope the stockholders here will interest themselves on this point, and make the incentive too strong to be resisted.

We are pleased to learn, that the representations made at the last meeting of the Directors, has tended to strengthen their confidence in the value of the stock and the practicability of constructing the road, at an early day. On the 16th of September, the letting will take place. A celebration is contemplated on the 17th, in commemoration of the commencement. All the magnates of the land are to be invited,—Clay, Webster, Harrison, Van Buren, McLean and Gov. Lucas. Every thing indicates success to the Mad River and Lake Erie

Railroad, if proper exertion is used. Let the present favorable period for securing it not be lost for lack of exertion. The means will come for the asking, if the request is accompanied by proof of our own faith in that for which we ask the money and the confidence of others. We cannot believe our citizens will allow this auspicious period to pass by without showing that they properly appreciate its importance. No great work was ever accomplished without persevering exertion; and it was so wisely ordained. We believe Dayton possesses sufficient enterprise and activity, for the emergency, if it can be aroused. These have too long remained torpid. We hope the invigorating prospect now presented, will warm them into new life and action.

**WARSAW AND LE ROY RAILROAD.**—We have been informed by one of the Commissioners, that Mr. J. Hurd, Engineer, will, on the first of next week, commence the survey of the route of this Road, and that it is intended to prosecute the survey, and the construction of the said Road, where it shall be located without further delay.—[Le Roy Gazette.]

**WINCHESTER AND POTOMAC RAILROAD COMPANY.**—We learn from the Winchester Republican that at the annual election by the stockholders on Saturday last, John Bruce, Esq. was re-elected President of the company, without opposition, and Messrs. Nathan Parkins, Jacob Senseney, Jos. H. Sherrard, and Isaac Hollingsworth, were elected Directors—who, together with Messrs. John R. Cooke, Richard W. Barton, and Gerard B. Wager, (appointed on the part of the State,) form the board for the present year.

The receipts of the Boston and Providence Railroad, last week, were, \$4,900.

The Charleston Mercury of the 13th, remarks: A respectable West India Merchant of this city, in connection with the agent of the steam packet plying hence to New York and Norfolk, and Captain James Pennoyer, master and sole owner of the new and superior steam packet Dolphin, have determined to make a voyage in the Dolphin from Charleston to Havana, with the view of forming a line of steam packets from Charleston to Havana, and probably by connection with others, thence to New Orleans. The Dolphin will positively leave Charleston for Havana, via St. Augustine, Cape Florida, and Key West, on Tuesday the 10th November next. Persons of respectability disposed to join the party can address to William Patton, Agent, Charleston, with cash enclosed, or proper references. The price of passage is \$40.

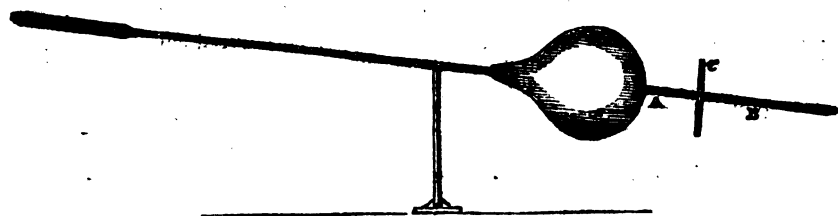

The Dolphin is a perfectly new boat, of most beautiful model, a superior engine, and heavy copper boilers, copper fastened and coppered, elegantly fitted for fifty passengers, and well found in every respect. Of the commander the public need no additional information; he was the very first to introduce successfully, Atlantic steam navigation, and is not surpassed as a skillful steam navigator and polished gentleman.

The Pittsburg Manufacturer of Saturday says: 'The Ohio River is too low for steamboat navigation.'

**STEAM CARRIAGES.**—A new steam carriage was recently tried, setting out from Westminster bridge and returning thither, after visiting Denmark Hill and Dulwich. The distance, twelve miles, was performed in 41 minutes.

**NEW METHOD OF MEASURING DISTANCE.**—An ingenious artist has invented an instrument termed a Distance Register, capable of being applied to two and four wheel carriages of every description, for the purpose of ascertaining the ground gone over by such carriages in any given space of time, from one minute to the whole day, and which may be employed with equal efficiency in reckoning the course of either steam or sailing vessels.

**METHOD OF BUILDING CHIMNEYS THAT WILL NOT SMOKE.**—Contract the space immediately over the fire so you may be sure of the air being well heated there: this will ensure a current upwards. All chimneys should be carefully built, and every joint well filled with mortar, so as to prevent communication in case of fire.—[Dr. T. Cooper.]

[From the Repertory of Patent Inventions, &c.]  
**Specification of the Patent granted to JAS. and JOHN HARTLEY, for a certain Improvement or certain Improvements in the Manufacture of Glass.** Sealed October 22, 1834.

Our invention relates to part of the process employed in the manufacture of that description of glass called crown glass, used for the purpose of glazing windows and other purposes. It is well known that this description of glass is produced from the metal by blowing the same into the form of globes, and afterwards, by means of the operation called "flashing," such globes are thrown open into flat circular plates called tables. Now, our invention relates to that part of the process of manufacture which consists in blowing the metal into globes. According to the ordinary process, the metal when taken from the pot by the pipe is rolled on a smooth iron surface, in order to bring the outer end of the metal to a conical form, the extreme end of which becomes the outer axis of the globe during the operation of blowing and working the glass into the required form. This outer axis is called the bullion. During the expanding of the metal into the globular form, the workman rolls the bullion along a straight edge, or bar, called the bullion bar, as is well understood. In doing this, the outer end of the glass globe, whilst expanding, and continually revolving, rubs against the bullion bar, by which action parts of the surface of glass is disturbed or made irregular, and as the globe extends in dimensions this rubbed surface enlarges: the consequence is that when the table of glass is complete, there are at all times more or less waved lines for some inches around the bullion or the centre of the table of glass, which lessens the value of so much of the table. This prejudicial appearance is produced to the glass as before stated by that part of the surface coming in contact with, and rubbing against, the bullion bar, when the metal is in a soft and pliant state. Now, the object of our invention is to dispense with the bullion bar, and to supply its place by the application of a tube or hollow bearing for the bullion or outer axis of the globe of glass during the expansion of the same: by this means that part of the surface which was heretofore rubbed against the bullion bar, is, when worked according to our invention, in no way prejudicially acted on, and the waved appearance before consequent on the manner of operating is avoided.

The drawing represents an ordinary pipe with a globe of glass, the bullion, *a*, being supported by the tube, *b*, in which it is caused to revolve by the workmen when working the metal into the globular

form desired during its expansion. On the tube *b* is placed a shield, *c*, which is intended to prevent the heat coming from the heated glass, injuring the hands of the boy who holds the tube. The workman, in performing this part of the process of manufacturing glass, takes a proper quantity of metal on the end of the pipe, and proceeds to form the outer end of such metal into a cone; he proceeds with the process in like manner to that heretofore pursued till the globe of glass requires support at the outer end by its axis or bullion, *a*, that is to say, he proceeds in the ordinary manner up to the period at which (according to the old means of operating) the bullion would have been rested on, and revolved, and run along the bullion bar, but in place of so running it along the bullion bar, a boy holds the tube or hollow bearing, *b*, in such manner as to receive the bullion, *a*, and the workman causes the globe to revolve till the globe is sufficiently expanded. The same is then to undergo the operation of flashing as heretofore.

Having thus described the nature of our invention, and the manner of carrying the same into effect, we would have it understood that our invention consists in the application of the tube or hollow axis, *b*, in place of running the bullion along the straight edge, called the bullion bar, as above described.

Enrolled April 22, 1835.

**COOKING BY GAS.**—We described some days ago, an application of gas to cooking, which we had witnessed, at the house of Mr. L. Snydan, in this city. The annexed article from a London paper, treats of more extensive applications:

**APPLICATION OF GAS TO ECONOMICAL AND DOMESTIC PURPOSES.**—It generally happens that as the progress of discovery is slow, we are long in developing the full advantages arising from improvements in science or its application to useful purposes. We are led to remark this from the very successful application of gas to a variety of purposes for which it has not hitherto been employed, in heating buildings, and performing every variety of culinary operation, and which, by the very ingenious plans adopted by Mr. Ricketts, has been brought into full and successful practice. The great heat eliminated in the combustion of the common street gas is a matter of every day notice, and it appears that Frederic Winsor, its first introducer, was aware of its availability for all the purposes of heat, as in his first prospectus he issued proposals for a gas light and heat company; but, with the exception of the cooking apparatus recently patented by Mr. Hicks, and exhibited at the National Gallery of Practical Science, and some prior attempts by Mr. Mallet of Dublin, this is, we believe, the first time that in addition to its purposes of illumination, its application to other useful purposes has been shown on any commensurate scale. The plan of heating buildings, patented by Mr. Ricketts, is perfectly novel, and from the most cursory description of its principles, it will be easy to understand its full merits and advantages.

In a stove similar in shape and construction to a common German stove, and with a very considerable radiating surface, a series of jets of gas are consumed, the size of the flame and the supply of gas

being proportioned to the diameter of the stove.—An orifice at the bottom admits a supply of air for the support of combustion, and one at the top in form of a chimney carries off the gaseous products of combustion. By this simple and equally efficacious arrangement a great quantity of heat is produced and radiated, an air chamber likewise over the surface of the flame distributing a large quantity of heated air. In confirmation of the advantages of this plan, we can refer to the Church of St. Michael's, at Burleigh street, in the Strand, where a stove of twenty-two inches in diameter is found amply sufficient to produce a temperature of fifty seven degrees in all parts of the building. Objections on the score of danger are readily obviated, by the apertures being made nearly air-tight, the escaped gas, if such should occur, readily finding a vent through the chimney. In the case we have instanced, the total consumption of gas is but at the rate of fifteen to twenty cubic feet, or an expense of between five and six shillings per diem, whilst the attention is confined simply to lighting the gas over night, when in the morning the church throughout is found warmed to the most genial temperature.

The arrangement for culinary purposes is on a plan equally simple & ingenious, different compartments being arranged in a neatly constructed chamber for performing the different operations of boiling, baking, stewing, roasting, &c., by different jets of gas being placed on an adapting and transferring axis. It is sufficient to state that whilst, by this plan, the heat is more uniform than by any other mode of procuring it, when any substance, as in roasting, is exposed to the direct action of the flame, instead of any injurious effect being produced the meat may be better cooked by it, being subjected to a well regulated and uniform heat.

Amongst the various inventions and discoveries of the day, this cannot be considered the least important. In many cases it is desirable to obtain and employ heat without subjecting to the formation and consequent noxious influence of smoke; and we perceive the ingenious inventor has suggested the employment of his stoves, within the arches under the viaduct of the Greenwich railroad, and thus render available, by their conversion into dwelling houses, an extensive property of that company which without them would be valueless. The power of large companies in providing a supply of the means and comforts of life at a great reduction of expenditure is apparent, when the cost of the supply is taken into consideration, and the gas companies at large cannot fail to appreciate an application which will render their commodity more greatly and beneficially available to the public at large.

#### AGRICULTURE, &c.

**INDIAN CORN—RUTA BAGA INJURIOUS TO IT, &c.**—The prospect for a fair crop of corn begins to brighten since the warm weather and the rain of the 16th, but the worms of different kinds and sorts have dealt hardly with it, and some fields are nearly ruined by them.

We have seen one field however which surpasses all others. It belongs to Mr. Eliphalet Folsom, of Monmouth. It is an early variety which he cultivates, and on the 15th was spindled out. Mr. F. has a farm with a soil of the right quality for it, and he has paid much attention to the cultivation of early varieties of crops, and by attention and care he succeeds remarkably well. The consequence is, that while his farm yields him a fair profit he does not suffer with that dreadful malady, the "Ohio Fever," which "has carried so many off."

While looking over his corn fields we noticed one thing which we believe is invariably to be found (this year at least) in other places under like circumstances. It is this—wherever Ruta Baga was cultivated last year and Indian corn planted on the spot this year, the crop is small. One side of a field of his was planted last year to Ruta Baga, and the corn on that place this year, though manured as well as the other,

is not more than half as high or good as the other.

We have seen this also in several other places. One in particular where the ground was highly manured this spring, but still it looks as if something was wanting, and does not grow. What does the Ruta Baga take from the soil that the corn needs?—  
[Maine Farmer.]

[From the Baltimore Farmer and Gardener.]

**GIBBES' IMPROVED CORN.**—We publish below, from the Yorkville (S. C.) Patriot, a brief though pithy correspondence between two practical farmers, on a subject of great moment to the agricultural interests. It was very happily said by Dean Swift, that "whoever could make two ears of corn, or two blades of grass, to grow upon a spot of ground where only one grew before, would deserve better of mankind, and do more essential service to his country, than the whole race of politicians put together," and we believe we may accord to each of those gentlemen the full measure of that meed of praise, without subjecting ourselves to the imputation of being a flatterer.

The method of selecting his seed corn, as followed by Mr. Gibbes, is judicious, and we trust every agriculturist who raises a corn crop will take counsel from the result of his experience, and pursue the same course. Indeed, were planters and farmers, generally, to adopt this plan, with respect to the saving of their seed from the whole range of their several crops, we have no doubt but that the happiest effects would be the result of their labors, in their melioration and improvement. Domestic animals in Europe, and particularly in England, have been brought to their present perfection by selecting exclusively for breeding those combining the best points for the respective uses for which they were wanted; and we see no reason why the same law which regulates the economy of the animal kingdom may not, with equal success, be applied to the vegetable. The experiments of Mr. Gibbes, and those of every other gentleman who has made the trial, go to confirm the belief that such would be the case. We, therefore, are impelled to the belief, that by exercising due vigilance and proper care in selecting seed corn from none but such stalks as are vigorous and large in their growth, fruitful in their yield, and which may have borne two ears or more of good grain, and by being equally careful in the culture, that in a few years, our planters would be able to banish from their corn fields those unsightly dwarf stalks which yield nothing but nubbins, and reward the husbandman so indifferently well for his toils and his outlay.

September 17, 1834.

**Friend:** Two years last spring I obtained some of your seed Twin Corn. I send in return one stalk with five good ears on it, and if you improve said corn for the space of two years and return me a stalk with six ears, raised on the pleasant fields of Oakley farm, I will try to be able in two years after to return you a stalk raised on the fertile fields of Busrow farm with seven ears. With due respect and esteem, I am yours &c.

W. S. GIBBES.

Oakley Farm, Sept. 18, 1834.

**Old Friend:** I have to thank you for your note and stalk of corn with five good ears upon it, and must acknowledge that you can beat me with my own seed, and that I can show nothing like it; nor could I hope

on my poor ridge of land to compete with your excellent farming on your flat bottoms—'tis now about 18 years since I first began to improve my corn, by selecting my seed from these stalks only which bore two ears; and the first year had difficulty to find as many stalks with two ears as would give me seed; but now, in a tolerable season, it is difficult to find a few stalks even with less than two, and from that to three and four good ears. The peculiar quality of my seed has shown itself particularly this year, when my whole crop has suffered so severely with drought, yet you see two ears or a struggle for it wherever my seed was sown; but two fields, sown each with different seed that had been highly recommended to me, there is scarcely a double eared stalk to be found in either—the few there are I shall carefully preserve and endeavor to improve, as I like the kind of grain rather better than that I am now cultivating. I shall preserve your five ears carefully also—plant them separately—and next year, Deo volente, let you know the result—though I can hardly expect my land can support and bring to maturity such prolific offspring. Believe me as ever, with regard,

WILMOT S. GIBBES.

OLD COL. GILL.

[From the Cultivator.]

**THE Madder CROP.**—Hon. J. Buel: Sir, As I consider the madder crop to be one of importance, as well to the grower of the article as to the country at large, I deem it proper to send you a few lines, giving some details of the most improved method of cultivating and preparing the article for use; which, if you deem them worthy a place in the Cultivator, you are at liberty to insert.

The land best adapted to this crop is a retentive, strong, loam soil, moist, but so situated that the water may pass off in the wet seasons of the year. The plant accommodates itself to almost any soil; for I last fall harvested a piece that yielded at the rate of 5,000 pounds to the acre, (in hills,) which was in a dry loamy soil, suitable for the wheat or corn crop.

The method of planting has been formerly in hills, from four to six feet apart. The hills yielded from two to three pounds of ground madder each, on good land.

Madder growers have lately made great improvements in the mode of planting. The drill method was introduced two or three years since, and is now the only way practised by those who raise madder in any considerable quantities. The first drills that were planted were set in single rows, about six feet apart, and eighteen inches from plant to plant. These were found to be too near together, both for the good of the crop and the convenience of tending it. It is now ascertained that the best method of planting madder is in beds six feet wide, with four rows of plants to a bed, leaving a space between the beds nine feet wide unoccupied; or it may be planted with rows of corn or potatoes the first season. This space is useful for various purposes, as passing with a team to carry manure, should it be considered necessary during the first and second seasons. The manure should be cropped between the beds, and mixed with a plough before it is used in the beds.

Particular care should be taken at the time of planting, that the ground be not too dry. It should be covered with clear, moist dirt, about two or two and a half inches deep. Soon as it has come up, it should be carefully hoed and cleared from weeds. When it is six or eight inches high, the tops

should be covered up nearly to the ends; and covered again soon as they are six or eight inches high, as before. In the fall, before the frost kills the tops, they should be covered entirely up. It is then left to lie till the next spring. It should be managed in the same manner during the second as the first season; but requires only two dressings before covering up in the fall. During the third season it should be dressed once certainly, and twice if practicable; and by this time the tops may be expected to cover the ground nearly from one bed to the other. During the fourth season, it requires no attention till the time for digging, which may be any time in the months of September or October. At digging time, the tops should be cut off with a scythe, rolled out of the way; then, with a plough, cut a deep furrow on each side of the bed, afterwards take dungforks and shake the dirt from the roots. They may then be picked up. Proceed in this manner till the whole bed is dug; washed clean, and dried in a hop kiln. A stove is preferable to charcoal for drying. Fifty bushels of roots may be dried in a kiln 12 feet square. They should be turned while in the kiln, at least once in six hours, until they are thoroughly dried, which takes from 36 to 40 hours. When taken out of the kiln, they should be taken immediately to the mill for grinding. Madder has formerly been ground in grist mills, but a much more convenient and economical way is to grind in cast iron mills constructed expressly for grinding madder. They also answer a valuable purpose for grinding coarse grain for provender, in sections of country where grist mills are not near by. They may be propelled by horse power, (one horse being sufficient,) or by water power if it is convenient. One of these mills will grind 800 or 1,000 pounds a day with one horse. Improved mills of this kind can be obtained by applying to me, at West-Winfield, Herkimer county, or Lester Curtis, Nelson, Madison county. Orders for mills will be promptly attended to: price \$20.

The following bill exhibits nearly the cost of cultivating an acre of madder, including the expense of digging, drying, and grinding.

Seed per acre,	\$32 00
Interest of land, 4 years at \$40,	11 20
Ploughing and harrowing twice,	2 50
Planting,	2 00
Dressing first year,	8 00
" second "	7 00
" third "	3 00
Digging,	21 00
Drying, 25c. per cwt.,	12 50
Grinding "	12 50
<b>Total cost,</b>	<b>111 70</b>

Product if well cultivated, 5,000 pounds, at 20c. per pound,	1,000 00
Deduct cost,	111 70

**Nett profit,** \$888 30

A good crop of madder looks small the first season, but those interested need not be discouraged. I have now planted nine acres, and shall be ready at the season for digging to supply seed to a considerable amount. Those who wish for seed had better obtain it in the fall. Quantity per acre as I plant, 8 bushels.

Price of seed: Under six bushels, \$4 per bushel; over 6 and under 12 bushels, \$3.50; over 12 bushels, \$3.

Respectfully yours,

HERBERT WOODBERRY.

West-Winfield, N. Y., July 20, 1835.

[From the same.]

**BEET SUGAR, &c.**—J. Buel, Esq.: Sir,—I recollect a few years since of seeing an account of sugar being made somewhat extensively, in some parts of France, from beets. As this part of the country is at some distance from the sea-board, and also destitute of the sugar maple, which renders sweetening quite expensive, if you are acquainted with the kind of beet used, together with the process of manufacturing, you will oblige many of your subscribers by inserting the same in the Cultivator. Or, if you are acquainted with any other substitute, it would be equally acceptable.

Should it not be foreign to the object of your paper, will you please to give us a recipe for making "India Rubber Varnish," for rendering leather water-proof? And here, permit me, without being suspected of flattery, to add my name to the list of encomiasts of your valuable paper. I think the two first numbers of the second volume are worth the price of the year's subscription; at least they are so to me.

Yours, respectfully,

WM. A. JONES.

Dexter, (Mich.) May 12, 1835.

**Reply.**—Mr. Jones' inquiry may be important to the far west, for the reasons he has stated. We therefore subjoin a description of the process of making beet sugar, as given by Chaptal, who was at the same time an extensive manufacturer of the article, and an eminent chemist, with some other facts connected with the subject. Our quotation is from Orfila's Practical Chemistry, p. 129-30.

"The beets are sown at the end of March or in April, [last of April or first of May with us,] when frost is no longer to be apprehended; it seems nearly indifferent whether the seed of the red, yellow, or white beets are taken. The earth most proper for their cultivation is that which has depth, and at the same time is light and rich; that which comes from the clearing up of meadows, alluvial soil dunged and long worked, are preferred for this purpose. These grounds should be prepared by two or three very deep ploughings, and a sufficient quantity of manure. The beets are sown at random, like wheat, and it is then harrowed; this mode has more advantages than that of sowing by the hand, the drill plough, on beds, or in the nursery. All the plants which grow near the beets, and whose vicinity is very hurtful to them, are pulled up by the hand or a weeding hook. The period of taking up this plant differs greatly, according to the climate; in the environs of Paris, and even at forty or fifty leagues from the capital, we should proceed to take them up in the beginning of October, whilst in the middle countries this operation should take place much sooner; without attending to this, it happens that the sugar formed is decomposed by the process of vegetation, and is replaced by nitrate of potash.

"After stripping the beets of their leaves, they are placed in the open air, on a very dry soil, beyond the reach of inundation, and which is covered with some pebbles and straw: the beets are placed in beds, in the centre of which a hole is left to give

exit to the vapor, and the beds are covered with straw. These precautions are indispensable—since, on the one hand, the beets freeze at 1° to 0°, (32 to 34°, Fah.,) and on the other, they germinate at 8 or 9°, (48°, Fah.,) especially if the air is moist. It would be more convenient to preserve them in barns and granaries; but it is almost impossible to find a situation of this kind capable of holding all the beets we want. If, nevertheless, we choose to put them into magazines, we must, 1, leave them in the field some days to dry; 2, uncover them when the temperature is only a few degrees above zero, unless it rains; 3, separate the heaps, remove the frozen or putrified beets, and renew the beds, [piles.]

"**Extraction of the Sugar.**—We cut off the necks and small roots of the beets, and scrape the surface with knives. They are reduced to a pulp by means of cylindrical graters, [similar, probably, to our grater cider mills,] moved rapidly with the hand, or by some contrivance. The pulp is pressed, at first, in small lever presses, and then by much more powerful ones; by this plan, we procure from 65 to 75 per cent of juice, which marks from five to ten on Baum's areometer. This juice contains, besides those substances found in the juice of the sugar cane, malic and acetic acids, and scarcely will it afford more than three or four per cent. of sugar. It is received in a boiler called the clarifier, which is heated when one-third or one-half filled. When the temperature is 65 or 66° (Cent. = 150° Fah.) the fire is stifled. We then throw into the boiler about 48 grains of lime, slaked with warm water, for every quart of juice, and the liquor is then brought nearly to ebullition; it is taken from the fire, and on its surface is soon perceived a layer, which is skimmed off. The liquid is then made to run out by means of a stop-cock fixed at the distance of a foot from the bottom of the boiler.

"The liquid is quickly boiled, and sulphuric acid diluted with 20 parts of water is poured on in the proportion of one-tenth of the lime employed; it is stirred, and it is better the mixture should have a slight excess of lime than of acid. We mix with the liquor 3-100 of animal charcoal, perfectly fine; for instance, that which is produced in the preparation of Prussian blue. Immediately afterwards, we add half of the charcoal which has served in a former process, and the boiling is continued until the liquid marks 18° or 20° on the areometer; it is suffered to rest until the next day, when it is strained through a woollen cloth; it is then put into a round boiler, two feet in breadth and ten inches high; this is one-third filled, and it is again boiled. If the contents are burned, the fire is relaxed, and the liquor is stirred; if the bath foams much, a little butter is thrown in, and the heat moderated. The boiling is ended, when, on taking a little of the syrup between the thumb and fore-finger, and quickly separating them, a thread is formed, which breaks dry. At this period the fire is covered, and after some minutes the syrup is poured into coolers, and from thence into the cones"—after which it may be subjected

to the processes of refining or claying, like West-India sugar.

The manufacture of beet sugar was prosecuted in France extensively during the late war; but on the return of peace, was in a measure abandoned. It has recently been revived, and is said to be rapidly increasing; and land for beet culture lets for a higher rent than any other production. About 18,000,000 pounds, or 18,000 tons, are said to be produced annually, and the profits are so great that it has been recommended to the French legislature to tax it for revenue.

According to the tables of Dubrunfaut, the average product, in Flanders, in ten cases cited, was 23,751 killograms the hectare. The killogramme is about 2½ pounds; the hectare 2½ acres. He estimates the raw sugar at four per cent. on the weight of the roots, the pulp to be worth 12 francs (about \$2.28) per ton, for feeding stock, and the molasses worth something additional for distillation. Dr. Achard obtained 6 lbs. 3 oz. raw sugar from a quintal of roots. Dubrunfaut estimates the cost of the sugar to the producer at about five cents per pound; at the manufactory of M. Crespell, the cost was 6 to 7 cents per pound.

Chemistry has discovered a new material for sugar, in wheat, the great staple of the west. It was first announced by a Russian chemist, M. Kirchoff, that starch may be converted into sugar, by being boiled for some time in very dilute sulphuric acid; and M. The. Saussure found that 100 parts of starch made 110 per cent. of sugar, and he concluded that sugar is merely a compound of starch and water. According to M. Berzelius, starch and common sugar are thus composed, though other chemists make the component parts of sugar somewhat different: Starch—Oxygen 49.6, Carbon 43.5, Hydrogen 7.0; Sugar—Oxygen 49.856, Carbon 43.265, Hydrogen, 6.979. Hence, the abstraction of a little hydrogen and carbon would convert starch into sugar.—[See Brewster's Encyclopaedia.]

The butternut affords sugar. We have a sample before us. The maker informs us that the butternut yields as much saccharine matter as the maple. Our sample is not well granulated, having been merely made as an experiment.

WOOL AND HAIR are known to possess highly fertilizing properties—they are, in reality, like bone and horn, concentrated manure. Until recently, refuse flocks of either could not be obtained in any considerable quantity: but our manufactories now afford them to such an extent as to entitle them to the farmer's notice. We have employed hair, combined with oil, from a seal skin manufactory, in considerable quantity, and with the best effect. Woolen factories furnish considerable waste flocks, combined with grease and dirt. Mr. Jabez Burroughs, of Watervliet, has been experimenting with these, and informs us that they exceed all other manures, when applied in one third the quantity that hog manure is applied.—[Cultivator.]

**STRAW CUTTERS AND OTHER AGRICULTURAL IMPLEMENTS.**—We spoke in another paragraph of the great saving which would accrue to the farmer or planter, by cutting the hay and straw with which he may feed his stock, and we will now call his attention to the several machines at present mostly approved of.

There is the 20 inch cylindrical straw cutter, suited to horse or water power, and competent to the cutting of from 75 to 100 bushels per hour. This, on a large estate, where time is emphatically money, would be found of immense value.

Of the same construction, there is the 14 inch box, suited to manual power, and the 11 inch box, also adapted to manual power, and both in high repute with agriculturists, being easily kept in order, and of great capacity. They are all self-feeders, and from the peculiar form of the knives, and mode of application to the straw or hay to be cut, can be worked a long time without sharpening, which circumstance is of itself of decided advantage.

And then there is the common Dutch Straw Cutter, with and without treadle, whose good service is familiar to a large number of farmers.

These several kinds range from 75, 45, 27, to \$20, and even so low as \$5.

When so much convenience is to be secured from such a small sum, with a positive certainty of saving one third the quantity of food, no farmer or planter should hesitate a moment, if he has not already done so, in supplying himself with a machine.

But while we are enumerating other inventions, we must not omit to name the straw cutter recently introduced by Mr. Secor, a neat, convenient machine, which appears to combine both the economy of time and power, and although a stranger among us, comes well commended to public favor.

Of *ploughs*, there is the Self-Sharpening, the Wood's, the McCormick's, the Sinclair & Moore's improved, the Bar Share, the Hill Side, the Shovel Plough, the Cary Plough, the Buffalo Plough, (an approximation to Mr. Jefferson's plan,)—these, of all their various numbers, sizes, and prices, have been so improved of late as to leave but a barren field for future essayists in improvement to glean in.

Nor should we here omit to mention that most excellent implement, the *Cultivator*, which, though neither plough nor harrow, answers a better purpose than either for *cultivation*. This is a machine which we fear is not sufficiently known; for, of a certainty, it is one of the best things introduced into the business of husbandry for fifty years, and deserves a conspicuous place on every farm.

But to conclude our article—we would in an especial manner call the attention of every raiser of corn throughout this land of mountain and dell, of endless rivers, and countless lakes, to the corn sheller; for in verity it is the most potent little labor-saver we have ever seen.

We allude to the one with a vertical iron wheel, with spring holders, competent to be adapted to the size of any ears. These by hand will shell you out from 15 to 20 bushels of corn in an hour, and it does its work so notably, and with such becoming cleanliness, as to take every grain from off the ear. From witnessing its operation the other day, we should think it would cure a lazy fellow of the ague and fever, who would feed it for a day.

But then we have our misgivings about recommending so *positive* an *innovator* upon the good old fashioned customs of the country. One thing is certain, that wherever one of these vertical gentlemen may show his face, there will be an end to those delightful corn husking and shelling squeezes, whose discordant sounds, and boisterous revelry, come down to us hallowed by the fond associations of an hundred years.

Well, be it so, this is the age of invention, and why should not its march be extended to those who cause the fields to teem with vegetable life, as well as to any other class.

But badinage aside, one of these diminutive machines, by hand power, worked 12 hours in a day—and they do not occupy more space than a flour barrel on its end—would shell 500 barrels of corn in two weeks. What the saving would be, every farmer can calculate for himself, and therefore we will content ourself with simply saying, that the other day, in witnessing a trial of its skill, we were literally astonished; before we thought the ear of corn was fairly in the sheller, it had performed its office, and the grains were lying at our feet.—[Balt. Farmer and Gardener.]

**THE NEGLECTED LADIES' SLIPPER.**—We see by a notice in the August number of the Horticultural Register, that at a meeting of the London Horticultural Society, in May, a number of beautiful flowers were exhibited, and among them a *North American plant*, called the *Ladies' Slipper*, which, it is added, is the most brilliant plant that has ever been brought to England. So the poor neglected *Ladies' Slipper* has found favor at last! Than which, a more beautiful flower, one of richer or more varied hue, does not adorn a river; but it is *common*, and that is enough to seal its fate. We have in our view, while we are writing this, a giant stalk of *imperial purple flowers*, as double as leaves can make them, as glossy as satin, and in the *tout ensemble* presenting a sight more beautiful than Cleopatra in all her loveliness and glory; but still it is but a *ladies' slipper*—an American ladies' slipper, and like the prophet of old, it has to go out of its own country in search of honors.—[Balt. Farmer and Gardener.]

**NATURAL HISTORY.**—M. Dussumier, a merchant at Bourdeaux, has presented to the Garden of Plants several living animals of great rarity, among which are the *diziguetai*, or *humione*, the wild horse from the centre of Asia, which has never before been seen in France; the *ours jongleur*, an Indian boar, a sheep of the pure Asiatic breed, a stag, from the Axis, and several apes and monkeys. —[Paris Advertiser.]

[From the Cultivator.]

*Circular addressed to the Raisers, Inspectors, and Consumers of Hops.*

At a meeting of the brewers of the State of New-York, convened in the city of New-York, 6th March, 1835, to take into consideration the causes of the present ruinous and improper practice of picking, curing, and inspection of hops, by which a very large proportion are rendered worse than useless, and others materially injured, a committee was appointed, and their chairman made the following report:

In presenting this communication, it is unnecessary to make any other remark to those interested, than to refer to the important facts that are here disclosed, to show that prompt and efficient measures ought to be taken to effect a radical change in the present system of picking and curing, as well as a corresponding change in the standard of inspection of hops.

We ask the patient indulgence of brewers, farmers, and inspectors, for the liberty we shall unavoidably be compelled to use, in pointing out the errors that have been fallen into. Your committee are aware of the great difference between persuading a man of the truth of any new proposition, with that of convincing him he is wrong, and satisfactorily inducing him to take the way of truth. We know we have one difficulty to contend with, to surmount which we are apprised will require not only all our ingenuity, but also all the forbearance of those concerned. This difficulty is the ready sale of hops in our market, in the imperfect condition they are now produced. The farmer would naturally enough ask why all this clamor about lupulin resin, early and late picking, while we can get 16 cents per pound, and 2,000 pounds per acre, near (\$320 per acre,) per annum? This is all fair enough, and we will further admit, that some individual who may ask this question has himself produced hops worth the money, and as good an article as either this or any other country is capable of producing; but our complaint is that there are but very few of this fine quality, not one bale in ten. We think we speak advisedly, when we repeat, that out of the 8,500 bales, the produce of New-York and the eastern states, there may not be more than 8 or 900 bales in prime order; that we may be perfectly understood, we earnestly solicit a careful perusal of an analysis of hops by Dr. Ives, of New-York, and published in Silliman's Journal of Science, 2d volume. Since which, the attention of many of the first chemists and physicians, French, Scotch, and English, have carefully experimented on them, and the result has been nearly the same. In one *essential particular* they all agree, which is that the only valuable properties are contained in the resinous globules, which Dr. Ives calls *lupulin*. These globules are not formed until a few days before the hop is ripe, and if picked either a few days too soon or too late, the hop is an injury instead of being of any service, as they possess neither preservative nor medicinal qualities. The experiments of Dr. Ives are so nearly correct, and as he merits the gratitude of his countrymen for his labor and skill in first bringing these matters before the public, we will copy a part of them, that they may be the more extensively known, and hope the valuable and important facts they disclose may have their just influence in correcting the many errors that have obtained, in the picking, curing, and inspection of hops.

**EXPERIMENTS.**

"Two drachms of leaves of the blossom

of the hop, from which all the lupulin or farina had been separated, were digested 12 hours in six ounces of boiling water. The infusion was bitter and exceedingly unpleasant to the taste; it possessed none of the aromatic flavor and peculiar bitter of the lupulin. When filtered and evaporated, it yielded five grains of nauseous extract.

"The same leaves were again digested in six ounces of proof spirits; after 12 hours the infusion was filtrated, and by evaporation yielded five grains of extract similar to the last. The same leaves were digested 24 hours in alcohol: the infusions manifested none of the sensible properties of the hop; it gave by evaporation four grains of extract. The taste of none of the extractive matter obtained, from the leaves, was sufficiently characteristic of the hop to designate that it was obtained from that article.

"From this, and other similar experiments leading to the same results, I think it is conclusively proved that the virtue of the hop resides exclusively in the lupulin; that the leaves contain a nauseous extractive matter which is imparted to water and to alcohol, and which, instead of adding to the bitter and aromatic flavor of the lupulin, partially neutralizes or destroys it.

"The obvious inference from these results have, as I conceive, been demonstrated—that the lupulin alone contains the bitter principle and the aromatic flavor of the hop, which are essential to the excellence and preservation of malt liquor."

These discoveries of Dr. Ives, immediately brought the attention of M. M. Payne, and M. Chevallier, two of the most eminent chemists of France to this subject. The learned compiler of the *Materia Medica*, Brevater's Edinburgh Encyclopædia, Doctor John Bostock, M. D. F. R. S., Dr. Paris, an able, profound medical writer, all agree that the lupulin is the only valuable part of the hop; and Dr. Paris particularly mentions the hop as the most valuable ingredient in ale, its stomachic qualities powerfully aiding digestion, "and particularly useful to the lower classes, enabling them to digest their innutritive food;" he says Dr. Franklin was wrong in condemning ale, and deprecates "the disappearance of small beer from the tables of the rich, as there was nothing to replace the tonic of the hop."

From the above authorities there is one certain fact established, which proves conclusively that the leaves forming the pod of the hop contain nothing of value for the purpose of brewing; an acrid nauseous bitter, the only properties they possess.

In looking back to the qualities of hops the markets for the last fifteen years have furnished, our opinion is, that the standard has gradually deteriorated; many are now branded *firsts* which have been picked before the resin had begun to form in them, and a very large proportion of those branded *firsts* are picked before the hops are ripe, and the resin or lupulin but partially appearing, being only sap, as soon as dry it is dissipated, and very shortly after, not even the smell of the aroma is perceptible.

This principal error of picking hops before they have arrived at maturity, is followed by another, as far as it goes, equally pernicious; using brimstone to give them the appearance of maturity,—hence our markets are furnished with first-rate hop pods or leaves, without any lupulin, possessing only the nauseous, acrid bitter, of unripe vegetation, and charged with sulphuric acid, the most deleterious matter to a vinous fermentation.

Various circumstances have combined to

bring about this lamentable state of things. The inspector is not the principal in fault for branding as *firsts* those which are *refuse* from early picking and brimstone. This error no doubt had its origin with mistaken men conducting the brewing business, and ignorant of either the culture, curing, or their essential properties. These men wanted hops that would impart no color to their liquor, and advised the inspectors, that hops, when ripe, were refuse, because when ripe, the leaves forming the head of the hop acquired a brown or yellow tinge, slightly coloring the ale; consequently, the inspectors have branded those hops *firsts*, which are gathered *green*, before the lupulin is formed in them, and from this ill-advised source, brimstone has been introduced and applied to both early and late picked hops; to the early, to take away the green, and to the late, to take away the brown color, and bleach them all to the imaginary pale ale standard. By this pernicious course, the rinds, if we may so term them, are substituted for the fruit, and for the wholesale aromatic resin, we are presented with an acrid, unhealthy bitter.

"Another cause may explain why our markets are yearly retrograding, which is, the early demand for shipping, or a scarcity among the brewers; hence often enormous prices are paid for trash, not worth the cartage for manure. This early demand makes numbers eager to avail themselves of the chance of advanced prices and the first sales, while they run no risk of the inspectors condemning them, from early picking. The farmers also find their interests served in early picking, as it gives a much longer time for harvest, enabling them with but trifling help, and less kiln room, to secure their crop: and can we blame them, while brewers and inspectors second their wishes?

We have no personal feelings, nor intend attaching censure to any individual; but insist that our present standard of inspection is an imposition; it does not indicate the maturity or intrinsic value of the hops. To be a competent judge of hops, requires experience, and a nice discrimination; it is impossible for any man to decide, correctly, unless he is capable of distinguishing every peculiar odor that hops may have; his sense of smell must be acute; it is not enough that the hops are dry, that they look well on the outside, that they have not been heated, smoked, stewed, brimstoned, or burnt: they must have the strong, pungent, aromatic smell of the hop when ripe, and just plucked from the stem; they must have the small globules of resin or lupulin, like gems surrounding the cove of the pod, and covering the bottom of the calyxes or leaves; without this lupulin they are refuse. All which is respectfully submitted.

L. FIDLER, Chairman.

**Resolved**,—That this report meet the approbation of the trade.

R. BOYD, President.

M. VASSAR, Secretary.

The above report was transmitted to the brewers of Pennsylvania, and the following gentlemen were appointed a committee, who concurred with the brewers of the state of New-York, in the adoption of the above report.

George Pepper, Frederick Gaul & Sons; Samuel N. Gray; Hutchinson & Stump; Abbott, Newlin & Co.; Francis & W. J. Perot; M. L. Dawson; Thos. C. Luders. Philadelphia, June 18, 1835.

[We have received for publication the circular of the Pennsylvania brewers, which we deem it unnecessary to insert, as the opinions it expresses accord with those in the preceding circular.]

**Remarks of the Conductor.**—We cheerfully give insertion to the above communication, as containing matter worthy the notice of farmers, particularly of the hop grower. And we beg leave to suggest to the worthy fraternity of brewers, as the most ready and efficient means of improving the hop culture, the propriety of offering liberal premiums for the best samples of hops that shall be exhibited at the Albany October Fair. This is a great hop market, and the crop will then be mostly ready for sale. It will be the means of congregating together the growers, buyers, and inspectors; of instructing all in the criteria which indicate the first quality; of demonstrating the relative value of good and bad parcels; and of instructing the growers in the best methods of curing their crops. Let a judicious committee be appointed, to decide on the relative merits of the parcels shown; to point out defects, explain the causes of them; and to report facts, with directions for managing the curing process. All parties would be benefited by the arrangement here recommended.

**THE GRAIN WORM** is literally destroying our wheat fields. The product of this crop in our vicinity will probably not be equal to the seed sown, although but for the worm the prospect was flattering. We do not know how far south and west the evil has extended. Steeping the seed in brine, and liming it, has not proved to be a preventive. We invite communications on this subject.

The warm and wet weather in the month of July has also been prejudicial to the wheat crops, in causing rust, which it is well known checks the circulation of the sap, and causes the grain to shrivel. It is a received opinion, that the grain ceases to enlarge when it becomes badly affected with rust, and that it is most advisable to cut it, though not arrived at maturity.—[Cultivator.]

[From late English papers.]

**SILK CULTURE.**—A company has been formed in Norwich for rearing silkworms. They are possessed of 120,000 of these valuable insects, in a most healthy state, and have planted 1,000 mulberry trees for future provisions. In the meantime contributions of mulberry leaves have been liberally afforded by many gentlemen who are desirous of encouraging the undertaking.

**AMERICAN ALOE.**—One of those sights which are said to occur but once in a century, the blooming of the American aloe, will shortly take place in a specimen of the variegated variety at the Surrey Zoological Gardens. It is believed to be about seventy years old; the crown of the plant opened on the eighth of June, and the flower-stem has been growing at the rate of about four inches a day; it is calculated by gardeners that it will reach to the height of from 24 to 28 feet, that the number of flower-buds will be from three to four thousand, and that it will continue flowering nearly six weeks. The period at which the agave arrives at maturity varies according to circumstances; in hot, or otherwise favorable climates, it grows rapidly, but in milder regions, or under the care of the gardener, it requires the longest period that has been assigned to it, which has given rise to the popular error, that the flowering occurs only once at the end of one hundred years.

The subject of exportation of flour from this country to America, in consequence of its high price in the United States, and the low value it realizes here, has excited some interest at Liverpool.

**PATENT LAWS.**—Lord Brougham brought in a bill to alter and amend the law of patents. The objects intended were generally to facilitate the obtaining of patents, and to secure the enjoyment of them to the inventors.

## NEW-YORK AMERICAN.

AUGUST 15—21, 1835.

## SUMMARY.

CAPTAIN BACK.—The Montreal Gazette says—

As our citizens have always taken a lively interest in this expedition, we think it right to lay before them again the instructions which Capt. Back received from Government, shortly before leaving England, (as detailed by the Arctic Land Committee, in the prospectus published by us in April, 1833,) and then so far as we are able, from the information we have been able to procure, afford them a brief sketch of what was actually accomplished. After directing him to place himself at the disposal of the Hudson's Bay Company, the instructions ran thus:—

"To leave Liverpool early in February, and to proceed with his party by way of New York to Montreal, and thence along the usual route pursued by North West Traders, to Great Slave Lake, which it is hoped that he will reach by the 20th July. He is then to strike off to the north-eastward, or in such other direction as he may ascertain to be the most expedient, in order to gain the Thew-ee-cho, or Great Fish River, which is believed either to issue from Great Slave Lake, or to rise in its vicinity, and thence to flow with a navigable course to the northward till it reaches the sea. On arriving at the banks of this river, he is to select a convenient situation for a winter residence, and immediately appoint a portion of his force to erect a house thereon; but, if possible, he is to proceed himself with an adequate party, and explore the river to the coast the same season, erecting a conspicuous land-mark at its mouth, and leaving notice of his intention to return the ensuing spring, in case Captain Ross should be making progress along this part of the shore. He is to take care, however, to return before the commencement of winter, to avoid any undue exposure of his men. During the winter he is directed to construct two boats capable of navigating the Polar Sea; and, as early as possible in the ensuing spring, again to descend its shores.

"His proceedings afterwards are necessarily left much to his own judgment. He is first to push on to Cape Garry, where His Majesty's late ship *Fury* was wrecked; on the remaining stores of which it is known that Capt. Ross in some measure relied; but in making for this point, whether by the east or west, he will be governed by the position of the mouth of the river, and other local circumstances, as he progressively ascertains them. While passing along the coast, he is to keep a vigilant lookout upon the shore for any signal or indication of the party which he was in search of (particularly at the entrance of the Hecla and *Fury* Straits, should he take the eastern passage;) and in the event of his meeting them previous to his arrival at Cape Garry, he is to offer to return and conduct them to the Hudson's Bay Settlement.—Or, should he find any indication of their having been on any part of the coast before his arrival, he is to search minutely for some memorial, that may lead to the discovery of their intentions; and proceed, in the event of success, in whatever practicable direction may seem best calculated to lead him to them. But whatever may be his prospects of success, he is on no account to prolong his search beyond such a period of the year (varying from the 12th to the 20th of August, according to the distance he may have attained) as will ensure his return to his winter quarters before the severe weather sets in; as on his acting in this particular with due caution, may depend the eventual safety and success of the whole expedition.

"On his return to his temporary establishment he is carefully to examine the state of his supplies communicating also with Great Slave Lake, to ascertain whether additional stores are there collected for him. And if he finds that he can, with reasonable prudence, devote a second summer to the service on which he is engaged, he is directed to do so, proceeding in a different direction to that previously traversed; but if not, he is to return to England in the following spring.

"Subordinate to the object of finding Capt. Ross, or any survivors or survivor of his party, he is to direct his attention to mapping what remains unknown of the coast which he visits, and making such other scientific observations as his leisure will admit, for which purposes the requisite instruments have been supplied to him. But he is not for such

objects, to deviate from his principal pursuit, until he shall have either succeeded in its accomplishment, or satisfactorily ascertained that its success is impossible."

During the winter, the expedition had to endure great privations and sufferings, owing to the scarcity of food, and the severity of the weather. On the 25th of April, being exactly one year after he had left Lachine, and during a very heavy snow storm, the despatch communicating Capt. Ross's safe return was delivered to Capt. Back. The primary object for which the journey was undertaken being thus happily fulfilled by other agents, Capt. Back made preparations for complying with the secondary part of his instructions—the examination of the coast between Point Turnagain and Ross's Pillar. Several boats were with the utmost activity built during the winter, but in spring, finding that they had an insufficient supply of provisions, they could only take one with them. It was not until the month of July, 1834, that the expedition got to open water on the Thlew ee-chodezeth, or Great Fish River. Captain Back, we believe, succeeded in determining that this river runs to the northward, and if we understand the purport of the scanty information which has reached us, it has its source on a height of land, about 150 or 200 miles from Fort Reliance, the winter establishment of the expedition, at the eastern extremity of Great Slave Lake. Capt. Back is the first European who has visited Great Fish River, and examined its course to the Polar Seas. Its very existence was doubted by many geographers. It is said to be large, but dangerous of navigation—greatly impeded by ice, and having little but mounds of sand along its banks. It falls into the Polar Sea, at a point, as far as we can learn, that coincides very near to the place assigned to it by Captain Back and the Arctic Committee in London, in their prospectus already referred to.

Farther than this, we only know that the party of intrepid travellers had to encounter every obstacle to which polar navigation is liable, and we are led to believe that immense masses of ice, accompanied by uncommonly severe weather, finally arrested their progress.

How far the labors of the expedition will increase our knowledge of the line of coast, we are unable to say; but from what has been stated above, it is obvious that a new route has been opened to the Polar sea, and that a large blank which formerly struck the eye, on surveying the map, will now in a great measure be filled up.—Captain Back will, we believe, have much interesting information to communicate, respecting his observations on the Aurora, the changes on the needle, as he drew Northward, &c. The extreme cold, experienced, we learn, was 70 deg. below zero.

The expedition returned to Fort Reliance, which place Captain Back left on 20th March, 1835, and travelled on snow shoes to Fort Chipewyan.—From this station he departed on 28th May, and arrived at Lachine, as already mentioned, on the 6th inst.

Thus has terminated an expedition undertaken from the most generous and lofty motives of which our nature is susceptible, pursued with the utmost ardor and zeal, and conducted in safety through dangers and difficulties of no ordinary kind, with the most consummate wisdom.

Captain Back arrived in Montreal this morning, and will leave for New York in a day or two, in order to embark in the packet ship of the 16th inst. for Liverpool.

The President of the United States returned to Washington on Monday, from his visit to the Rapids.

The Jersey City Ferry has, it will be seen, reduced the rate of ferriage on pleasure carriages. This will have the effect, doubtless, of tempting citizens in search of pleasant drives, to cross the Hudson for them.

It is said that the population of Springfield, Massachusetts, has increased within five years about twenty-five per cent. In 1830, it was 6,784: it is now 8,411.

It is stated that the annual worth of all the mechanical and manufacturing products of the United States, is about five hundred millions of dollars.

[From the Philadelphia Gazette.]

THE GIRARD CHAIR.—Our readers are acquainted with the fact that the Board of Trustees of the Girard College charged Dr. Lieber with drawing up a plan of education for the great institution to be erected by the munificent bequest of our late fellow citizen. The Board ordered Dr. Lieber's report to be published, and both in French and German periodicals which concern themselves with subjects relating to education, not to speak of our own American journals, this complete and able work of our townsman has been spoken of in high terms. We are particularly pleased to notice the nineteenth No. of the London Quarterly Journal of Education, published under the superintendence of the Society for the Diffusion of Useful Knowledge, where an article on the same work with copious extracts and many flattering remarks, will be found. The reviewer says towards the end of this article: "The sound views developed by Dr. Lieber gives us reason to expect the eventual success of the College from which we trust that the U. States will derive every advantage that her best friends can wish."

In regard to that portion of the Report, however, in which Dr. Lieber expresses his opinion, that it could not have been the design of Mr. Girard to exclude religion from the College, the Reviewer seems to take exception to it. He thinks the Dr. has not construed the will with sufficient strictness, which, to say the most of it, is charging him with a bias that can injure no man who has charge of a literary institution.

The cause of civilization has at length really become a general and international cause, and while we find a London periodical recommending the remarks of Dr. Lieber to general attention, we see that an official report made to the Legislative Council of Geneva, refers to our penitentiary system as the most perfect, and to Dr. Lieber's remarks in his translations of the work of Mons. Beaumont and Torqueville on the same subject, as of great importance in this cause of absorbing interest. Dr. Lieber has been elected to one of the chairs in the S. Carolina College at Columbia, whither, as we understand, he will shortly proceed. We congratulate this Institution upon the acquisition of so capable and learned a Professor, and doubt not that the anticipations of those who have been instrumental in placing him there, will be fully realized.

GREAT STEAMBOAT SPEED.—The steamboat Robert L. Stevens, Capt. Dean, left New York at fifteen minutes past twelve o'clock last night, and arrived here fifteen minutes past nine this morning, making her trip in nine hours. She made no landings.

We are indebted to Mr. Holdridge, the second officer of the R. L. Stevens, for the New York Sun of this morning, from which we copy several items of news.—[Alb. Evening Jour.]

INCIDENT.—We are informed that yesterday when the train of cars on the Germantown Railroad was in full motion, an object was descried on the road, and the velocity of the car was checked. On approaching nearer a child was found lying in the road asleep. Its little arm and head were resting on the railroad, and it was some time before the unconscious innocent was awakened.—The youngster had probably got tired of play, and selected this perilous pillow to enjoy a comfortable nap.—We may remark, by the way, that the managers of the different branches of this road deserve great credit for their care and vigilance. At starting and stopping the engine, large crowds collect around the cars, and nothing but the constant and commendable attention of the managers would prevent the frequent occurrence of deplorable accidents.—[Phila. Gaz.]

A layman in Providence, who occasionally exhorted at evening meetings, thus expressed his belief in the existence of a Deity:

"Brethren—I am just as confident that there is a Supreme Being as I am that there is flour in Alexandria; and that I know for a certainty, as I yesterday received from there a lot of 300 bbls. fresh superfine, which I will sell as low as any man for cash."

This reminds us of a passage in a sermon we once heard in Alabama—"You are all gone astray," said the preacher, "you are all sinners, and have gone astray—just as my horse did when I was up in Kentucky lately, and I ha'n't found him yet, and you must supply me with another

in his place, for I can't afford to preach for nothing and lose my horse too."—[Philad. Com. Herald.]

**THE MECHANIC.**—Under this name, a new penny paper has made its appearance. It is edited by THOMAS N. CARR, and is to be mainly devoted "to advocate the interests, and defend the rights, of the mechanics as a body." We doubt the expediency of all plans having a tendency to separate one class of our multifarious and busy population from another, by appeals addressed exclusively, or peculiarly, to them. We are in the eye, and in the practice, of the law, all equal—have all, common rights, and may alike aim at every public station. The best mode, therefore, of defending the rights, and advocating the interests, as well of mechanics, as of men of all other callings, is, to inculcate generally, obedience to the law, mutual forbearance, strict morality, and the constant practical application of that golden rule of Christianity, "do as you would be done by."

The first number of this little paper is lying before us, and subject to the exception above stated, seems to us to be well got up. Its editorial matter is good both in style and thought.

**EPISCOPATE OF MICHIGAN.**—Many of our readers are aware that the Rev. Henry J. Whitehouse, D. D., rector of St. Luke's Church, Rochester, has been elected to the episcopate of Michigan at the recent Convention of the Episcopal Church, held at Tecumseh. We are sorry to learn that Dr. W. has declined the election, as well as the rectorship of St. Paul's Church of this city, which had been tendered to him. There not being sufficient time to call a special convention of the Diocese to make another election before the meeting of the general convention, the probability is, that this diocese will continue to remain for the present under the episcopal charge of the bishop of Ohio.

For the information of those who may feel interested, we will state that the vestry of St. Paul's Church in this city, having anticipated the decision of Dr. Whitehouse, have taken steps to procure a rector without delay; and the two wardens, who are now absent to the convention in Philadelphia, are clothed with power to make such an engagement, as to them may seem proper.—[Detroit Journal, 11th Aug.]

To the Editor of the N. Y. American :

As there was some mistake in your paper in relation to the commencement at Union College, will you have the goodness to insert the annexed paragraph in your next No., and oblige many of the friends of old Union.

At the Commencement at Union College on the 2d ult., 88 members of the graduating class received the degree of A. B.; and the honorary degree of A. B. was conferred on Wm. Belden, sen. of Brooklyn.

The honorary degree of A. M. was conferred on Amos W. Brown, Adam Crounce, Lyman Cobb, and Dr. Caleb Ticknor, of New York. The same degree was also conferred on 20 alumni of the college. Rev. John Breckenridge, received the degree of D. D., and R. B. Taney, and Abram Van Vechten, of Albany, that of L. L. D.

**A CHURCH IN THE "FAR WEST."**—As the eye of philanthropy gazes in astonishment upon the magically changing aspect of our wide and beautiful valley, and is delighted at the rapid advances of the car of civilization, which glides over its features—converting the wilderness into a garden,—like sun-shine chasing shadows along the bosom of the great deep—it is possible that a cloud of doubt may at times overcast the scenery—whether this valley will really become happier from the change which we are so wont to admire; and a tear of pity may fill the eye as she beholds the simple Aborigines driven far from the loved objects of their early and fond remembrance. She knows that the garden's produce is often inferior to that of the desert; that the first awkward efforts of art, will be but to mutilate those of nature, and well may her sighs mingle with those of the "spirit of the deep forest," as she looks on the ruthless inroads of the firebrand and the axe.

There are, however, some portions of the path traced by the wheels of civilization, which may be

viewed with a pleasure unclouded by doubts, or tears, or sighs,—those portions we mean, where religion was an occupant of the car. 'Tis true the Indian may thence retire, but he is followed by the Gospel of peace. The triumph there over nature, is not of art, but of grace. The simplicity of the savage there, is not the dupe of the white man's cunning, but the happy conquest of the high, the unsearchable "wisdom of God." The "mountains and the hills break forth into singing" there; the "trees of the field all clap their hands" in triumphant echo to each stroke of the thundering axe, and the wood-spirit rejoices as she beholds her proud oaks totter, for she knows they are to become pillars in the temple of JEHOVAH!

We were led into the train of thought that suggested the above, when about to write a notice that the Episcopal church edifice, now on the eve of completion in our village, would, on Sunday the second of August, be opened (the first time) for the celebration of Divine service.

Among the many pleasing objects that strike the eye of a visitor to this neighborhood, the building we have mentioned is by far the most attractive, and the one on which his gaze may rest with the most unmingled satisfaction. Passing over the higher reasons for the pleasure of the beholder, we would observe of our church, that in the simple, yet elegant grace of its external proportions, the commodious and tasteful arrangement of every thing within, and the picturesque and conspicuously situated ground of its location, it stands confessedly without a rival in the Territory of Michigan,—a noble, and we trust, not useless monument of the enterprise and zeal of Western Episcopalians, and of the beneficence of many residing at the East.—[Tecumseh Democrat.]

POST OFFICE DEPARTMENT, }  
August 11th, 1835. }

Abstract from the Journal for week ending this day.

## 1. POST OFFICES ESTABLISHED.

Scraper, Jackson co., Ala.  
Franklin, Jasper co., Mi.  
West Alton, Stafford co., N. H.  
Canada Line, Somerset co., Maine.  
North Garden, Albemarle co., Va.

## 2. POST OFFICES DISCONTINUED.

Chittenden, Calloway co., Ky.  
Allston's, Saint Mary's co., Md.

## 3. CHANGE OF NAME.

The name of the office at Taledogo, Noxubee co., Mi., changed to Macon.

## 4. APPOINTMENTS OF POSTMASTERS.

Pascal St. Clear, Scraper, Jackson co., Ala.  
William Ellis, Franklin, Jasper co., Mi.  
Jefferson Clement, Macon, Noxubee co., Mi.  
Abner Vaughan, Mount Vernon Furnace, Montgomery co., Ten.

Horace Look, Collinsville, Madison co., Ill.  
William T. Yeomans, Helena, Phillips co., Ar. Ter.

Israel F. Hall, House's Spring, Jefferson co., Mo.

Wardlow Howard, Middleburgh, Hardeman co., Ten.

Benjamin G. Estill, Cane Hill, Washington co., Ar. Ter.

Harvey L. Williams, Fruits, Calloway co., Mo.  
Charles Douglass, King William C. H., King William co., Va.

Gordon H. Wallace, Missouri, Saint Charles co., Mo.

Austin A. Gibbons, Sulphur Rock, Independence co., Ar. Ter.

Willis Dougherty, Martinsville, Clark co., Ill.  
Abner C. Beckham, Crocketts, Gibson county, Ten.

John Sawyer, West Alton, Stafford co., N. H.

Rufus Hilton, Canada Line, Somerset co., Me.

Thomson Armor, Monroe, Butler co., Ohio.

John Cummings, Canton, Bradford co., Pa.

William Atkinson, Franklin, Baltimore co., Md.

George Bowlby, Harrison, Hamilton co., Ohio.

Joseph M. Sterling Bryant's, Fayette co., Pa.

John Ferrall, Falls of Schuylkill, Philadelphia co., Pa.

Daniel Coleman, Jacksonopolis, Jackson co., Mich. Ter.

Jacob Morris, Lishaskill, Albany co., N. Y.

David S. Brown, Cheviot, Hamilton co., Ohio.

John Burnett, Landisburg, Perry co., Pa.

John R. De Noyelles, Punchill, Schoharie co., N. Y.

Peter L. Duboise, Olive, Ulster co., N. Y.

Matthew Fowler, Baring, Washington co., Me.  
John W. Stewart, Allen, Allegany co., N. Y.  
Joshua Maynard, Scipio, Seneca co., Ohio.

Legrand Mead, Edenville, Orange co., N. Y.

Zadok W. McKnew, Bladensburg, Prince George's co., Md.

John Young, Columbia, Columbia co., Ohio.

James Kinsolvin, North Garden, Albemarle co., Va.

Joel Forester, Watson's Grove, Green co., Ga.

Flemming Moseley, Scuffletown, Laurens District, S. C.

Thomas B. Wright, Mount Airy, Surry co., N. C.

William A. Austin, Bellefonte, Jackson co., Ala.

William F. Thomas, Briardleton, Burke co., N. C.

James Beverly, Churchville, Montgomery co., N. C.

Jared Irwin, Lumpkin, Stewart co., Ga.

Anthony D. Clark, Woodlands, Marshall co., Va.

John Weaver, Caldwell, Greenville District, S. C.

John B. Black, Milton, Laurens District S. C.

Elias H. Kemp, Foulton, Decatur co., Ga.

Simeon Lindsley, New Vernon, Morris co., N. Jersey.

Orin Hall, Navarino, Onondaga co., N. Y.

Ordered, that a fine of One Hundred Dollars be imposed on James Reeside, contractor on the route from New York to Philadelphia, for failure of the mail on the 3d inst.

By the schr. Jane, Capt. Davis, we have Bermuda papers to Aug. 8, inclusive. The Bermudian of 8th, says, "The conduct of the colored people in the past year, has been highly satisfactory; and we trust that they will take care of the kind persons by whom their future actions will be governed."

A bill was passed in the House of Assembly to encourage the introduction of Grist Mills in these Islands, granting the exclusive privilege to James Taylor, for a certain time.

Capt. Hatheway, of ship Saratoga, from New Orleans, left at 8. W. Pass, the United States cutter Ingham, Capt. Jones, on the eve of sailing for the Coast of Mexico, in pursuit of the notorious Thompson, commander of the Mexican schooner Corea,—proof having been adduced that said Thompson is impressing and exacting from each American \$300 for their release. The late Lieut. Com'dt of the Mexican schr. Montezuma; who ran his vessel on shore at the Brassos after firing into the Ingham, has been sent to Vera Cruz, for trial.—[Daily Adv.]

FROM NEW SOUTH WALES.—We have been favored with the Sidney papers to the 7th of March. Great joy was occasioned, about the last of February, by the arrival of a cargo of women from England. The value of this article in the Sidney Market, may be inferred from the fact that with a population of over 24,000 males in the Colony, there were only 10,000 females.—[Journal of Com.]

**BANGOR.**—There are ten blocks of brick buildings that will average six tenements to a block, and forty-six dwelling houses, now going up and finishing in this city; besides these, are cellars and foundations preparing for the erection of twelve more. This is exclusive of nearly as many substantial brick stores, now in progress in the business part of the city. The streets are undergoing a thorough reform, and all about us evinces a condition of general thrift and prosperity. As an exhibition of foreign and coasting business connected with Bangor, there were yesterday in the river, to be counted from the wharves, five brigs, forty schooners, and four sloops.—[Bangor Whig.]

**WASHINGTON COLLEGE.**—We have had the pleasure of attending the public Examination of Washington College, Hartford, which was continued for nearly a week, and have been gratified with the result. The President and Professors are laboring with zeal and ability to promote the welfare of the pupils and the prosperity of the institution.—[Churchman.]

Eighty thousand dollars have already been subscribed for the building of the Portland Exchange, Maine.

## Cleanings from European papers.

[From the London Athenæum of June 20.]

**REFORM.**—The Queen of England has set an example which has been followed by many of the nobility and gentry; she has availed herself of the hot weather to set the example of early hours, and, we believe, that a four o'clock dinner and a drive afterwards, is about to be fashionable: 8 and 9 o'clock in the evening has been the fashionable hour several years.

**DELAY OF PUBLIC BUSINESS IN THE HOUSE OF LORDS.**—Lord Brougham, adverting to the legislative business of their Lordships standing at zero, while the demand for improvement in the country was almost at the boiling point, recommended their Lordships to proceed with the discussion on the Irish Church question by means of resolutions, to which course both Lord Melbourne and the Duke of Wellington objected, one on the ground that it would add to their Lordships' labor without forwarding the public business; and the other on the ground that their Lordships, because all the information was not before them, were not ripe for the discussion. The arrears of the Court of Chancery, or of their Lordships' judicial business, is nothing to the arrears of their legislative business, which continually accumulates; and, however disagreeable it may be, their Lordships must speedily put their shoulders to the wheel, or their overburdened vehicle must forever stick in the mud.

**OPENING A MUMMY.**—Much curiosity has been excited in the scientific world by the opening of a mummy, brought by Lord Frederick Fitzclarence from Thebes. The ceremony took place at the new Anatomical Theatre at St. George's Hospital, in Kennerton street, Wilton place. The lecturers of the school having offered the premises for the occasion, the mummy was opened on Wednesday by Mr. Pettigrew, who delivered some interesting observations on the process of embalming adopted by the Egyptians. Prince George of Cambridge, Lord F. Fitzclarence, Lord Wilton, Count d'Orsay, Sir A. Cooper, Sir B. Brodie, Mr. Davidson the Egyptian traveller, &c., were present during the operation. The lady, for it was a lady, was discovered to have been a priestess of the Temple of Ammon, at Thebes. After a period of more than 2,000 years, she will repose in a glass case in the museum of an anatomical school.

**GOLD.**—The average of gold brought into England for the last few years was 1,630,000*l.* per annum. The far greater portion of this was used in manufactures and articles of jewellery. A considerable quantity was made into gold leaves, the intrinsic value of each of which was about one half-ling altogether a charge of three farthings for each leaf. On the average nearly two millions of these leaves were manufactured every week in London. Not more than one half of this was returned in another shape to the goldsmith; scarcely any portion, however, of the gold used in gilding frames was lost, as the Jews carefully looked after the old frames, and burnt the gold off. The ordinary wear and tear of the gold coins probably amounted annually to about one fiftieth part of their value.—[Professor Faraday.]

**THE WIDOW OF NAPLES.**—There dwelt in Naples a matron named Corsina, wife of a worthy cavalier, known as Raomondo del Balzo. Now it pleased heaven to take the husband of Corsina, leaving her an only child, named Carlo, who was in every way the counterpart of his father. Thus the mother resolved that he should inherit all her fortune, and determined to send him to study at Bologna, in order that he might learn all the accomplishments of his age. With this view she secured a master for her son, furnished him with books and every other necessary, and, in the name of heaven, sent him to Bologna. There the youth made rapid progress, and in brief time became a ripe scholar; and all the students admired him for his genius and loved him for the excellence of his life. In course of time the boy became a young man, and, having finished his studies, prepared himself to return home to Naples, when he suddenly fell into a sickness, which defeated the skill of all the physicians of Bologna. When Carlo found that death was inevitable, he thus ruminated with himself:—"I am not afflicted for my own sake, but for my disconsolate mother, who has no child save me, in whom she has garnered all her earthly hopes, and from whom she looks for future support, and for

the regeneration of our house. And when she knows that I am dead, and that, too, without her even seeing me, sure I am she herself will suffer a thousand deaths." Thus did he lament more for his mother than himself. Now, dwelling on these thoughts, he conceived a plan by which he hoped to lessen the bitterness of his death to his parent; to which end he wrote her a letter in the following words:—

"My dearest Mother,—I entreat that you will be pleased to send me a shirt made by the hands of the most cheerful woman in Naples—a woman who shall be free from every sorrow—every care."

This letter was despatched to his mother, who instantly disposed herself to fulfil the desires of her son. She searched throughout Naples, and where from outward appearance, she hoped to meet the woman free from sorrow, there she learnt a story of some lurking grief—some deep, though well-disguised affliction. At this, Corsina said, "I see there is no one free from misery—there is no one who hath not her tribulation: and they, too, who seem the happiest have the deepest cause of wretchedness." With this conviction she answered the letter of her son, excusing herself for the non-fulfilment of her commission, assuring him that, with all her search, she could not discover the person whom he desired might make the garment. In a few days she received the tidings of her son's death: it was then she felt the full wisdom of the lesson he had taught her, and with meekness and resignation bowed to the will of God. [The above is from the Italian of Fiorentino: the original story is disfigured by the faults of the age (1397) in which the author wrote. We have endeavored to present to our readers the exquisite sentiment of the tale, separated from the dross. Fiorentino is, we believe, but little known to English readers: he is, however, well worthy of their acquaintance.]—*Freemason's Quarterly Review* for July.

[From the London Literary Gazette].

## The History of the Assassins.

Translated from VON HAMMER, by C. O. WOOD, M. D.

After a general view of the state of the empires of the East, and the reigning families of the Omniades, Abbassides, Fatimites, &c., Mr. Von Hammer proceeds to his more immediate matter, and says:

"The Assassins are but a branch of the Ismailites; and these latter, not the Arabs generally, as descendants of Ishmael, the son of Hagar, but a sect existing in the bosom of Islamism, and so called from the Imam Ismail, the son of Jaffer."

He then treats of the foundation and progress of Islamism and its various sects; particularly of the *Imanie* (i. e. the tenets of the twelve Imams,) from which the Ismailite was a division. In the last (the ninth) degree of their initiation the disciples of this vile school were

"Perfectly enlightened as to the superfluity of all prophets and apostles, the non-existence of heaven and hell, the indifference of all actions, for which there is neither reward nor punishment either in this world or the next; and thus was he matured for the ninth and last degree, to become the blind instrument of all the passions of unbridled thirst of power. To believe nothing and to dare all, was, in two words, the sum of this system, which annihilated every principle of religion and morality, and had no other object than to execute ambitious designs with suitable ministers, who, daring all and honoring nothing, since they considered every thing a cheat and nothing forbidden, are the best tools of an infernal policy. A system, which, with no other aim than the insatiable lust of dominion, instead of seeking the highest of human objects, precipitated itself into the abyss, and mangle itself, is buried amidst the ruins of thrones and altars, the horrors of anarchy, the wreck of national happiness, and the universal execration of mankind."

The order of the Assassins was founded by Hassan Sabah, whose personal story, from youth upwards, till he established himself in power as the head of the mighty conspiracy, is one of wonder.

"Nothing is true and all is allowed," was the groundwork of the secret doctrine; which, however, being imparted but to few, and concealed under the veil of the most austere religionism and piety, restrained the mind under the yoke of blind obedience, by the already adopted rein of the positive commands of Islamism, the more strictly,

the more temporal submission and devotion were sanctioned, by eternal rewards and glory. Hitherto, the Ismailites had only masters and fellows; namely, the Dais or emissaries, who, being initiated into all the grades of the secret doctrine, enlisted proselytes; and the Refik, who, gradually intrusted with its principles, formed the great majority. It was manifest to the practical and enterprising spirit of Hassan, that, in order to execute great undertakings with security and energy, a third class would also be requisite, who never being admitted to the mystery of atheism and immorality, which snap the bonds of all subordination, were but blind and fanatical tools in the hands of their superiors; that a well organized political body needs not merely heads but also arms, and that the master required not only intelligent and skilful fellows, but also faithful and active agents: these agents were called Fedavie (i. e. the self-offering or devoted); the name itself declares their destination. How they afterwards, in Syria, obtained that of the Hashishin or Assassins, we shall explain hereafter, when we speak of the means employed to animate them to blind obedience and fanatical self-devotion. Being clothed in white, like the followers of Mokanna, three hundred years before, in Transoxiana, and, still earlier, the Christian Neophytes, and, in our own days, the pages of the sultan, they were termed Moboyese, the white, or likewise, Mohammere, the red, because they wore, with their white costume, red turbans, boots, or girdles, as in our own day do the warriors of the prince of Lebanon, and at Constantinople the Janissaries and Bostangis as body-guard of the seraglio. Habited in the hues of innocence and blood, and of pure devotion and murder, armed with daggers (cultelliferi), which were constantly snatched forth at the service of the grand-master, they formed his guard, the executioners of his deadly orders, the sanguinary tools of the ambition and revenge of this order of Assassins. \* \* \*

"The flat part of a country is always commanded by the more mountainous, and the latter by the fortresses scattered through it. To become masters of these by stratagem or force, and to awe princes either by fraud or fear, and to arm the murderer's hand against the enemies of the order, was the political maxim the Assassins. Their internal safety was secured by the strict observance of religious ordinances; their external, by fortresses and the poindard. From the proper subjects of the order, or the profane, was only expected the fulfilment of the duties of Islamism, even of the most austere, such as refraining from wine and music: from the devoted satellites was demanded blind subjection and the faithful use of their daggers.—The emissaries, or initiated, worked with their heads, and led the arms in execution of the orders of the Sheikh, who, in the centre of his sovereignty, tranquilly directed, like an animating soul, their hearts and poindards to the accomplishment of his ambitious projects."

The various gradations of rank and power under him are detailed, and the whole extraordinary organization explained. Hassan's "greatest policy (as is well stated) consisted in designing his doctrine of infidelity and immorality, not for the ruled, but only for the rulers; in subjecting the tensely reined and blind obedience of the former, to the equally blind but unbridled despotic commands of the second; and thus he made both serve the aim of his ambition,—the former by remuneration, the latter by the full gratification of their passions. Study and the sciences were, therefore, the lot of only a few who were initiated. For the immediate attainment of their objects, the order was less in need of heads than arms; and did not employ pens, but daggers, whose points were everywhere, while their hilts were in the hand of the grand-master."

At length:—

"So great was the dread in which princes held the order, that they did not dare to refuse them the strong places of their own countries, and preferred destroying them, to abandoning them for citadels of the power and sovereignty of the Assassins. \* \* \*

"Hassan Sabah survives the most grateful of his disciples, and his nearest relations, to whom the ties of attachment and consanguinity seemed to secure the highest rights to the succession to the sovereignty. His nephew and grand-prior in Syria, Abulfettah, had fallen by the sword of the enemy; Hossin Kaini, grand-prior in Kuhistan, under the dagger of a murderer, probably Ostad, one of the two sons of Hassan; and Ostad and his brother under the hand of their own father, who seemed

to revel even in spilling his own blood. Without proof of the measure of guilt, he sacrificed them, not to offended justice, but apparently to mere love of murder, and that terrific policy, by virtue of which the order snapped all ties of relationship or friendship, to bind the more closely those of impiety and slaughter. Ostad (i. e. the master), probably so called because the public voice had destined him as the successor of his father as grand-master, was put to death on the mere suspicion of being concerned in Hossein's murder; and his brother, because he had drunk wine; the former, probably, because he had by his crime, which was without orders, interfered with his father's prerogatives; the latter, because he had infringed one of the least essential laws of Islamism, but whose observance was part of the system of the order. In the execution of his two sons, the grand-master gave the profane and the initiated a sanguinary example of avenged disobedience to the ordinances of outward worship, and the rules of internal discipline; but, probably, besides this apparent motive, the son of Sabah was urged by another, to the destruction of his race; possibly, his sons, disgusted with the long reign of their father, were expecting with impatience to succeed him; it is probable, that on that account he deemed them incompetent, as not having learned to obey, or as being wanting in the necessary princely qualities; or, it is probable, that he set them aside, in order to avoid sinking the order into a dynasty by inheritance, and that the succession of grand-masters might be determined by the nearest relationship of mind and character, irreligion and impiety. Human nature is not usually so diabolical, that the historian must, among several doubtful motives to an action, always decide for the worst; but, in the founder of this society of vice, the establisher of the murderous order of the Assassins, the most horrible is the most likely."

The founder lived to the age of ninety, and was succeeded, during fourteen years, by a yet more bloody tyrant, Kiabusurgomid; of whose ferocity, and the devoted fanaticism of his followers the following quotation is a terrible evidence:—

"The less the designs of the Ismailites prospered by the sword, the more successful and persevering were they with the dagger; and, however dangerous to the order the times might be, they were not the less so to its most powerful adversaries. A long series of great and celebrated men, who, during the grand mastership of Kiabusurgomid, fell by the poinards of his Fedavi, signalized the bloody annals of his reign; and, as formerly, according to the fashion of oriental historians, there follows, at the end of each Prince's reign, a catalogue of great statesmen, generals, and literati, who have either adorned it by their lives, or troubled it with their death; so, in the annals of the Assassins, is found the chronological enumeration of celebrated men of the nations who have fallen the victims of the Ismailites, to the joy of their murderers, and the sorrow of the world. The first, under the grand mastership of Kiabusurgomid, was Cassim-ed-dewlet Aksonkor Bourahi, the brave prince of Mossul, feared alike by the Crusaders and the Assassins, as one of their deadliest enemies. Having fought his last battle with the former, near Maarra Mesrin, he was, on the first Sunday after his return, attacked by eight Assassins, disguised as dervishes, as he was in the act of seating himself on the throne in the Mosque at Mossul: protected by a coat of mail and his natural bravery, he defended himself against the wretches, three of whom he stretched at his feet; but before his retinue could hasten to his assistance, he received a mortal wound, from the effects of which he expired the same day. The remaining Assassins were sacrificed to the vengeance of the populace, with the exception of one young man from the village of Katarnash, in the mountains near Eras, whose mother, on hearing of Aksonkor's murder, dressed and adorned herself for joy at the successful issue of the attempt, in which her son had devoted his life; but, on his returning alone, she cut off her hair, and blackened her face, with the deepest sorrow, that he had not shared the murderer's honorable death. To such lengths did the Assassins carry their point of honor, and what may be termed their Spartanism. Moineddin, the vizier, of Sultan Sandjar, was also murdered by an Assassin, hired by his enemy, Derkesino, the vizier of Mohammed, and a friend of the Ismailites. In order the better to attain his object, the ruffian entered his service as a groom. One day, as the vizier went into the stable to inspect his horses, the false groom appeared before him without clothes, in

order to avoid all suspicion of carrying concealed weapons, although he had hidden his dagger in the mane of the horse, whose bridle he was holding.—The horse reared, and under pretence of quieting him with caresses, he snatched his poinard, and stabbed the vizier. If Bourahi, Prince of Mossul, stood on the list of the victims of the Ismailites solely because he was the rival of their power, and an obstacle to their greatness, we shall not be surprised at finding the name of Busi, the Prince of Damascus, by whose orders the vizier Masdeghani, and six thousand Assassins had been massacred. The slightest pretence was sufficient to cause the blood of princes to flow beneath their stiletos; how much more when their own called, as in this latter case, for revenge. To escape, was beyond the power of prudence, as they watched for years, for time, place and opportunity. Busi, the son of Togteghin, was, in the second year after the massacre, attacked by its avengers, and received two wounds, one of which healed immediately; the other was, however, mortal the following year."

Kiabusurgomid, by a great error, made the dignity hereditary in his son Mohammed, who, in turn, was succeeded by his son, Hassan II.; and he, after creating a wide and dangerous schism, by claiming to be himself Imam, and not, as heretofore, the Imam's precursor, was slain by his son, Mohammed II., who rose to be grand-master on the murder of his father. The next was Hassan III.; the next Alaeddin Mohammed III.; and the last Rokneddin, who, together with his infamous instruments, was destroyed by the Mongol conquerors of the countries, where they held sway during a hundred and seventy years.\* Of their char-

\* "The conquering power of Jengis Khan, thundering in the distance, had passed innocently over their heads, but under the third of his successors, Mangu Khan, the whirlwind of Mongols swept over the Eastern world, and, in its desolating progress, carried away, along with the khalifat, and other dynasties, that of the Assassins. In the year 582 of the Hegira (A.D. 1186), when the seven planets were in conjunction, in the sign Libra, as they had been a century before in that of Pisces, all Asia was trembling in expectation of the end of the world, which astrologers declared was to happen, the first time by a deluge, and the second by hurricanes and earthquakes. But if the first time, a swollen mountain torrent drowned only a few pilgrims in order not to put the prophecy to the blush; and the second, there was so little wind on the appointed night, that lights burnt freely: in the open open air on the top of the minarets without being extinguished; nevertheless, at both periods political revolutions came to the help of the astrologers' predictions, who had interpreted the conjunction of the planets as indicating physical changes. \* \* \* Mangu had already, some time before, issued the command to Hulaku to exterminate all the Ismailites, and not to spare even the infant at his mother's breast; and immediately upon Rokneddin's departure, the sanguinary task was commenced, which had only been delayed till Kirdkuh, and the remainder of the castles of the Assassins in Kunistan and Syria, should have fallen. He sent one of his viziers to Kaswin, to put death, indiscriminately, Rokneddin's wives, children, brothers, sisters, and slaves; only two relations, females apparently, of Rokneddin were selected from this devoted band, not for mercy, but to be the victims of the princess Bulghan Khatun's private revenge, her father Jagatai having bled by the Assassins' daggers. A command, similar to that given to the governor of Kaswin, was issued to the viceroy of Khorassan. He assembled the captive Ismailites, and twelve thousand of these wretched creatures were slaughtered without distinction of age. Warriors went through the provinces, and executed the fatal sentence without mercy or appeal. Wherever they found a disciple of the doctrine of the Ismailites, they compelled him to kneel down, and then cut off his head. The whole race of Kiabusurgomid, in whose descendants the grand-mastership had been hereditary, were exterminated. The 'devoted to murder' were not now the victims of the order's vengeance, but that of outraged humanity. The sword was against the dagger, and the executioner destroyed the murderer. The seed sowed for two centuries was now ripe for the harvest, and the field ploughed by the Assassin's dagger was reaped by the word of the Mongol. The crime had been terrible, but no less terrible was the punishment."

acter, during this period, we select a few instances:—

"Two years after the death of Conrad Montferrat, the Count of Tyre, and that of Rashideddin Sinan, Henry Count of Champagne, passed, on his journey to Armenia, near the territory of the Assassins; the grand-prior, the successor of Rashideddin Sinan, sent deputies to welcome him, and to invite him to visit his fortress on his return. The Count accepted the invitation, and came; the grand-prior hastened to meet him, and received him with great honors. He took him to several castles and fortresses, and brought him at last to one having very lofty turrets. On each look-out stood two guards dressed in white, consequently initiated in the secret doctrines. The grand-prior told the count that these men obeyed him better than the Christians did their princes; and giving a signal, two of them instantly threw themselves from the top of the tower, and were dashed to pieces at its foot. 'If you desire it,' said the grand-prior to the astonished count, 'all my whites shall throw themselves down from the battlements in the same way.' The latter declined, and confessed that he could not calculate upon such obedience in his servants. After staying some time at the castle, he was, at his departure, loaded with presents; and the grand-prior told him, on taking leave, that by means of these faithful servants he removed the enemies of the order. By this horrible example of blind submission, the prior showed that he trod exactly in the footsteps of the founder of the order, who had given the ambassador of Melekshah a similar proof of the devotion of his faithful followers. Jelaeddin Melekshah, sultan of the Seljuks, having sent an ambassador to him to require his obedience and fealty, the son of Sabah called into his presence several of his initiated.—Beckoning to one of them, he said, 'Kill thyself!' and he instantly stabbed himself; to another, 'Throw thyself down from the rampart!' the next instant he lay a mutilated corpse in the moat. On this, the grand master turning to the envoy, who was unnerved with terror, said, 'In this way am I obeyed by seventy thousand faithful subjects. Be that my answer to thy master. \* \* \*

"A youth, who was deemed worthy, by his strength and resolution, to be initiated into the Assassin services, was invited to the table and conversation of the grand master, or grand prior; he was then intoxicated with henbane (*hashish*), and carried into the garden, which on awaking, he believed to be Paradise; every thing around him, the hours in particular, contributed to confirm his delusion. After he had experienced as much of the pleasures of Paradise, which the prophet has promised to the blessed, as his strength would admit; after quaffing enervating delight from the eyes of the hours, and intoxicating wine from the glittering goblets, he sunk into the lethargy produced by debility and the opiate; on awakening from which after a few hours, he again found himself by the side of his superior. The latter endeavored to convince him, that corporeally he had not left his side, but that spiritually he had been wrapt [rapt] into Paradise, had then enjoyed a foretaste of the bliss which awaits the faithful, who devote their lives to the service of the faith, and the obedience of their chiefs. Thus did these infatuated youth blindly dedicate themselves as the tools of murder, and eagerly sought an opportunity to sacrifice their terrestrial, in order to become the partakers of eternal life. What Mohammed had promised in the Koran to the Moslimin, but which to many might appear a fine dream and empty promises, they had enjoyed in reality; and the joys of heaven animated them to deeds worthy of hell. This imposture could not remain undiscovered; and the fourth grand master, after unveiling all the mysteries of impiety to the people, probably revealed also to them the joys of Paradise, which could, besides, have but little charms for them, to whom already every thing was permitted on earth. That which hitherto had served as a means to produce pleasure, became now itself an object; and the effects of the intoxication of opium, were the earnest of celestial delight, which they wanted strength to enjoy."

With this we finish; and have only to add, that the general affairs of the East, during several centuries, are greatly illuminated by this account of one of its monstrous afflictions, and heartily recommend the volume to our readers, not only as a valuable companion to the real history of the Khalifates, the Crusades, &c. &c., but a curious associate

to the Oriental tales with which our leisure hours have been so much delighted.

Grey the poet, used to declare, that the sum of happiness consisted in lolling upon a soft sofa all day long, reading new novels.

**CIRCULAR.** To ENGINEERS and Superintendents of Railroads and Canals.—I am preparing to issue a new edition of my RAILROAD AND CANAL MAP; and being desirous to correct the errors of the first edition, I take the liberty to request the ENGINEER, or SUPERINTENDENT, of every Railroad and Canal in the UNITED STATES, to furnish me at his earliest convenience with a full and precise account of the condition of the railroad under his direction or charge. He is requested to state the length of the road, the number of miles completed, the elevation it surmounts, the radius of its curves, the style of its construction, its average cost per mile, the number, if any, of inclined planes, with stationary engines—in short, every thing which may be of interest to engineers, or others who may be connected with the subject of Railroads and Canals.

To such as comply with the above request, and furnish the desired information previous to the first of August next, a copy of the new edition of the Railroad and Canal Map, will be sent, by mail or otherwise, as may be directed, as soon as completed.

D. K. MINOR.

New-York, June 27, 1835.

#### RAILROAD JOURNAL AND ADVOCATE OF INTERNAL IMPROVEMENTS.

This work is published once a week, in quarto form of eight pages, devoted mainly to the subject of internal improvements, in all its various modes and forms. Three volumes were completed in December, 1834, and the 4th volume is now in progress.

Terms, \$3 a year, in advance. Previous volumes same price; full set of four volumes, \$12.

#### RAILROAD AND CANAL MAP,

Or a Map of the United States, 24 by 40 inches, on which is delineated all the Railroads and Canals in use, or in course of construction, and most of those in contemplation; together with a concise description of, or reference to, each, and containing over 70 pages of letter press. The map is on blank note paper, and put up in pocket form, with morocco cover, or in paper cover, and may be sent by mail to any part of the country Price \$2

#### MECHANICS' MAGAZINE, AND REGISTER OF INVENTIONS AND IMPROVEMENTS.

This work has nearly completed five volumes. It is published monthly, in numbers of 64 pages each, in large octavo form, and forms two good sized volumes a year, of 384 pages each.

This work is STEREOTYPED from the first number, and therefore any number of copies may be obtained from commencement, if desired. It has many able correspondents, who furnish original communications, in addition to its selections from the best European periodicals of the day, with numerous engravings and illustrations of the subjects on which it treats. The Mechanics' Magazine may be considered as one of the permanent periodicals of the country. Price, \$3 per annum, in advance. Previous volumes \$1.50 each.

#### THE APPRENTICE'S COMPANION—

A monthly publication, in large octavo form, of sixteen pages each number—designed to persuade APPRENTICES, and others, to habits of INDUSTRY, TEMPERANCE, and FRUGALITY—is published at the office of the MECHANICS' MAGAZINE, No. 35 Wall street, New-York, for FIFTY CENTS a year—for 12 numbers—by D. K. MINOR.

\* All letters must be postage paid. Eleven numbers sent to one address for \$5,—and TWENTY THREE for \$10. D. K. M.

#### NEW-YORK FARMER AND AMERICAN GARDENER'S MAGAZINE.

This work is devoted mainly to AGRICULTURE and HORTICULTURE; it, however, treats upon various other subjects more or less connected with them. It is now in its 8th volume, or 3d volume, new series, and is designed to be made equal to any work of the kind in this or any other country. No reasonable expense will be spared, either to secure the best writers the country affords, or to furnish engravings and illustrations. It is published monthly in large octavo, 32 pages per month, at \$3 per annum, and when paid in advance eight additional pages per month are given—Vols. 6 and 7, or 1 and 2, new series, \$3 per volume.

These works may all, or either of them, be had of S. Blydenburgh, 96 North Pearl street, Albany; D.

Hale, 124 Washington street, Boston; Fessenden, Philadelphia; or of the Proprietor and Publisher,

D. K. MINOR,

35 Wall street, New-York.

#### PARTNER WANTED.

Wanted, a partner in an extensive Printing Establishment. No one need apply who is not a thoroughbred printer, competent to superintend and direct an office in which upwards of 30 persons are employed, and able to furnish \$3000 cash capital. The best of references will be given and required. Letters, with real name, may be addressed to P. P. P. Post Office, New-York, postage paid, and they will be promptly attended to. May-15

#### NOTICE TO CONTRACTORS.

Sealed Proposals will be received at the Hudson and Berkshire Railroad Company's Office, in the city of Hudson, until the 5th day of September next, for excavating and embanking 14 miles of their Road from Arnold's shop, near Groat's, at Chatham Four Corners, to the state line, and also for constructing 8 Bridges, from 60 to 70 feet each, between the abutments. Plans of the masonry and superstructure of the bridges will be exhibited at the Railroad Office. Contractors will be required to furnish all the materials for bridges; and the masonry to be completed by the 1st of December next. The road to be graded for a double track, 24 feet wide. A part of the road will be heavy rock and gravel excavation. Profiles of this part of the route will be exhibited at the Railroad Office, in Hudson, and also at the Office of the Engineer, at Chatham Four Corners. The road will be divided into sections of one half and one mile each in length, and prepared for examination by the 10th of August.

Proposals will also be received for furnishing 500,000 feet B. M., of White Oak Rails, 6 by 7 inches square, and 16 feet long. Also, 15,000 Oak or Chestnut Ties, 6 by 7 inches square, 9 feet long, or, if round, not less than 8 inches in diameter, at small end. Also, 500,000 feet of Chestnut, Pine, or Hemlock Slits, 4 by 10 inches, 12, 16, or 20 feet long.

The whole to be subject to the inspection of the Engineer, and to be delivered on the line of the road, by the 15th of April, 1836.

The remaining 18 miles of the route will be put under contract as soon as the line can be prepared.

Persons applying for contracts will be expected, unless personally known to the Engineer, to present with their proposals recommendations as to ability to perform their contracts.

Any information on the subject afforded at the Engineer's Office, Chatham Four Corners.

JAMES NELLEN, President.

GEORGE RICH, Chief Engineer. 31—St

Hudson, Aug. 1, 1835.

#### TO TUNNEL MINERS, DRILLERS, &c.

Wanted, immediately, 40 Tunnel Miners, (Cornish Miners will be preferred,) 50 Drillers, 50 Laborers, and two experienced Mine Blacksmiths, on the New York and Harlem Railroad, about five miles from the City. Liberal wages will be given, and cash payments made every fortnight. Apply at Mr. FOWLER'S, St. John's Hall, Frankfurt street, New-York.

JOHN RUTTER, Contractor.

The Albany Argus, Philadelphia U. S. Gazette and Pennsylvania, will please copy this, and send their bills to the Railroad Company, 14 Wall street, New-York. 23—15

#### STEPHENSON,

Builder of a superior style of Passenger Cars for Railroads,

No. 364 Elizabeth street, near Bleecker street, New-York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. J36 15

#### RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order car wheels, chairs and knees, and every other description of castings required for railroads. R-15 1614

#### PATENT RAILROAD, SHIP AND BOAT SPIKES.

The Troy Iron and Nail Factory keeps constantly for sale a very extensive assortment of Wrought Spikes and Nails, from 3 to 10 inches, manufactured by the subscriber's Patent Machinery, which after five years successful operation and now almost universal use in the United States (as well as England, where the subscriber obtained a Patent,) are found superior to any ever offered in market.

Railroad Companies may be supplied with Spikes having countersink heads suitable to the holes in iron rails, to any amount and on short notice. Almost all the Railroads now in progress in the United States are fastened with Spikes made at the above named factory—for which purpose they are found invaluable, as their adhesion is more than double any common spikes made by the hammer.

All orders directed to the Agent, Troy, N. Y., will be punctually attended to.

HENRY BURDEN, Agent.

Troy, N. Y. July, 1831.

Spikes are kept for sale, at factory prices, by J. & J. Townsend, Albany, and the principal Iron Merchants in Albany and Troy; J. I. Brower, 223 Water street, New-York; A. M. Jones, Philadelphia; T. Janviers, Baltimore; Degrand & Smith, Boston.

Railroad Companies would do well to forward their orders as early as practicable, as the subscriber is desirous of extending the manufacturing so as to keep pace with the daily increasing demand for his Spikes. 1254em

H. BURDEN.

#### RAILROAD CAR WHEELS AND BOXES, AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS.

Also, Flange Tires turned complete.

J8 ROGERS, KETCHUM & GROSVENOR

#### PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

Railroad Spikes of every description required, made at the Albany Spike Factory.

Spikes made at the above Factory are recommended to the public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to admit water.

Orders may be addressed to Messrs. ERASTUS CORNING & CO., Albany, or to THOMAS TURNER, at the Factory, Troy, N. Y. sep.13-1y

#### RAILWAY IRON.

95 tons of 1 inch by 1/2 inch.	Flat Bars in lengths of
200 do. 1 1/2 do. 1/2	14 to 15 feet, counter sunk
40 do. 1 1/2 do. 1/2	holes, end cut at an angle
800 do. 2 do. 1/2	of 45 degrees, with splicing
800 do. 2 1/2 do. 1/2	plates and nails to suit.

250 do. of Edge Rails of 36 lbs. per yard, with the requisite chairs, keys and pins.

Wrought Iron Rims of 30, 33, and 36 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels.

Axles of 24, 28, 32, 34, 36, and 38 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment. A. & G. RALSTON.

9 South Front street, Philadelphia. Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them. d71meowr

#### SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by

E. & G. W. BLUNT, 154 Water street, corner of Maiden lane. J31 61

#### SURVEYING AND ENGINEERING INSTRUMENTS.

The subscriber manufactures all kinds of Instruments in his profession, warranted equal, if not superior, in principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Goniometer, with two Telescopes—and a Leveling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes.

WM. J. YOUNG.

Mathematical Instrument Maker, No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested. Baltimore, 1832.

In reply to thy inquiries respecting the instruments manufactured by thee, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish thee the following information. The whole number of Levels now in possession of the department of construction of thy make is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repair, except from accidents to which all instruments of this kind are liable.

I have found that thy patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a reversing telescope, in place of the vane sights, leaves the engineer scarcely any thing to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,

JAMES F. STABLER, Supt of Construction

of Baltimore and Ohio Railroad.

Philadelphia, February, 1833.

Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Germantown, February, 1833.

For a year past I have used Instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these Instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, AUGUST 29, 1835.

**BRIDGE BUILDING.**—We have received from a friend, a communication, with a drawing, of Lieut. G. W. Long's plan of bridge building, which we shall hereafter give to our readers.

**UTICA AND SCHENECTADY RAILROAD.**—This work is progressing rapidly. The grading is completed on nearly its entire line. Its termination is fixed at the lower end of Genesee street, near the Mohawk bridge, in Utica; and it will give life and activity to that part of the city, which has not improved, since the completion of the Erie Canal, as rapidly as other parts of the city.

**ENLARGEMENT OF THE ERIE CANAL.**—We understand that the "Canal Board" has decided to enlarge the Erie Canal to 60 feet wide and 6 feet deep. We regret exceedingly this decision—as we believe that the best interests of the State require that it should be at least enlarged eighty feet wide and eight feet deep. If the business has increased in ten years, or if, even in fifteen years, it shall so increase as that the present canal will not be capable of passing it—what may we not expect, when we know what has occurred, within the next forty years? Look at the almost boundless West—into which the industry and youth of the older States are setting in an over-

whelming current—and then estimate the amount of business which must naturally find an outlet through this State. If any thing has been learned by experience, it is that the present canal is altogether too small, and therefore it must be enlarged. If it must be enlarged, why not do it in such a manner as to render a second enlargement unnecessary? This would seem to be a reasonable question, and it should be properly and correctly answered; and now is the time, before the work is commenced, to answer it. Would it not therefore be proper for the citizens of New-York, who are so deeply interested in it, to express an opinion upon it? To us it appears a very proper subject of consultation, and we would therefore recommend it to their consideration.

**OLEAN CANAL.**—This work, it would seem, is not duly appreciated by the business men, and owners of real estate, in this city. It is highly important that measures should be taken at an early period to disseminate such information as will place the merits of the OLEAN AND ROCHESTER CANAL fairly before the people of the State, and respectfully before the citizens of New-York.

The route for this canal has been twice surveyed, and found beyond question practicable, and well supplied with water. It is well known that its route lays, a part of the way at least, through a thickly populated and well cultivated part of the country—and it is also well known that it will, when completed, connect two of the most important water communications, viz. the Ohio and Mississippi Rivers on one side, and the Erie Canal and Hudson River on the other—and that it passes through a region of country in which is found probably the best pine lumber brought to this or any other; and it is also believed, from the very strong indications that have been discovered, to possess immense quantities of coal. Thus it will be seen that, in addition to

the business which must necessarily pass through this canal, from the two great thoroughfares above alluded to, the country bordering upon it has resources of its own which will insure to it at least a fair share of business—and that these considerations taken together, with the very great increase of business which will naturally result from the construction of the New-York and Erie Railroad, which is now placed beyond a doubt, must satisfy even those who have before doubted, that this work will yield to the State a handsome profit, and at the same time greatly enhance the value of property on its line.

If these views are correct, it is a matter of great importance that early measures should be taken to arouse the people interested in its construction. What then is the proper course to pursue? Call a CONVENTION, we say, to be held at Rochester, some time in October, for the purpose of promoting the work. Let good men be selected from all those counties interested in the work, and especially from this city—who can give life and energy to the measure. From such a course good must result—or at least harm cannot.

**LABORERS WANTED.**—We are informed that laborers are wanted on the line of the Chenango Canal. Twelve or fifteen hundred men, we were recently informed, could get employment and good wages by applying immediately.

Quebec, 14th August.—Capt. Yule of the Royal Engineers returned from his reconnaissance of the route for the proposed Railroad to Maine, by the Chaudière and River du Loup. His report is more favorable than he anticipated himself. Being called to Montreal on a periodical service of a few days, he goes up to-morrow, having left his baggage in the country and not completed the Chaudière and Megantic reconnaissance. He met the Committee this afternoon.

There are only three places where slight obstacles occur, easily to be surmounted, viz.; Pointe Lévi, St. Mary's and the junction of the Rivière du Loup, a tributary of the Chaudière. Captain Yule intends examining the landing at the Pointe Lévi, to-morrow, and return from Montreal to proceed with the Chaudière reconnaissance, up which it was found impracticable to move from the lowness of the water.

[From the London Mechanics' Magazine]  
**Quick and Cheap Mode of Railway Transit  
 without Locomotive Engines.**

Mr. Editor,—A great deal has been said on both sides for and against the undulating railway principle, but hitherto no satisfactory practical results have been obtained on which to found a definitive judgment respecting it; and although the shareholders of the Liverpool and Manchester Railway are deriving considerable profits, owing to the immense traffic between the two towns, still there are doubts if many other roads will pay at all: the expense of locomotive engines being so great, wherever there are considerable inclines to be overcome, and the first expense of constructing the railway so enormous, from the endeavors made by tunnelling and embanking to reduce that expense. I am, therefore, induced to send you a new plan of an undulating railway, by which locomotive engines (except on very rare occasions, indeed,) will be dispensed with; the trains will travel by the force of their own gravity from station to station, as described in the above diagram.

E E are stationary steam-engines, and O O O inclined planes by which the stationary engines bring the trains up to a level, when the trains, going and returning, take the roads the arrows point to. I have no doubt but in many situations falls may be obtained each way for miles together. Deep cutting and tunnelling would be thus, in a great measure, dispensed with; and if tunnels in some situations were absolutely necessary, by giving them the required falls for the trains to go through them, by gravity alone, travelling through them would not be disagreeable, as no engine would go with the trains.

I am, Sir, your obedient servant,

THOMAS DEAKIN.

Blaenavon Iron-Works, June 5, 1835.

[From the London Mechanics' Magazine.]  
**Mr. Woodhouse's Angular Railway Bars.**

Fig. 1.

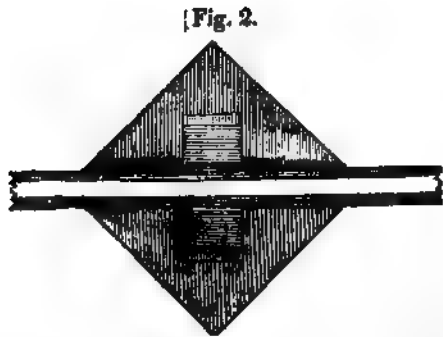

Fig. 2.

Sir,—As the form of rails best suited for affording safety, economy, durability, &c. has occupied the attention of many scienti-

fic persons, and formed the subject of several communications in your pages, I hope, without presumption, I may be permitted to propose the annexed as a plan, in my humble estimation, calculated to effect these objects.

Some few months since, I proposed the use of an angular rail; my plan was not then matured, but as I have since given some little attention to the subject, I send you the results.

The purpose of giving an angular shape to the rail is, that the engine wheel (also having an angular grooved rim to correspond) may have a greater hold upon the rail, thereby giving greater efficiency to the power of the machine, preventing an irregular action, which must be produced when the wheel slips on the rail (a circumstance much alluded to at the opening of the Selby Railway,) and thereby much strain to the machinery. The top surface, one inch broad, is intended for the train-wheels, and where friction would be a defect, it is thereby avoided. The form of the rail is intended to admit of being reversed at any future time when the upper surface is worn. The chair is not intended to be fixed, but the central part, which projects downwards, is to let into the stone sleeper, and be bedded in with cement or not, as found best. The rail is not fixed to all the chairs, but only to the centre one; which proposition I made with another plan of Rail and Chair sent to the London and Birmingham Railway Directors. The size of the present rail is as follows: Depth,  $4\frac{1}{2}$  inches; extreme width,  $2\frac{1}{2}$  inches; surface, 1 inch; angles, from  $15$  to  $25^\circ$ , as the friction is required; the calculated weight is rather more than 51 lbs., but upon shrinking, it would probably not be more than 50 lbs. to the lineal yard.

It has been objected to turning the rail when one side is partially worn down, that in proportion as it is so worn, its strength must be diminished. But as long as the internal structure of the rail is not so permanently injured as to prevent its return after deflexion to its original horizontal form, it seems to me that it must be nearly, if not to the full, as efficient as ever.

As respects the supporting of the rails, I also proposed that instead of having the rail resting solely upon the chair, the chair should be so planned that the rail should also rest upon the surface of the stone, whereby it would be strengthened, and the stone, by receiving a steady vertical pressure, would be rendered less liable to the casualties so frequently complained of.

I also proposed that the stone-block or sleeper should be placed in an angular direction with the length of rail or line of road, whereby a greater surface of stone would be placed in the directions most required, viz. lengthways and sideways. By this plan an 18 inch stone exposes a surface of 2 feet and more to the pressure.

Fig. 1 is a section of the rail as it rests in the chair, which, when the lower portion of the chair is let into the stone, will rest upon the stone also; the two small sections are for the purpose of fixing the centre of each rail to its chair. Fig. 2 is a vertical view, showing the angular position of the stone upon a smaller scale.

I am, Sir, yours respectfully,

P. WOODHOUSE.

Kilburn, May 27, 1835.

[From the London Mechanics' Magazine.]

#### MARINE STEAM ENGINES.

*Extracts from the Evidence given by Joshua Field, Esq. of the House of Messrs. Maudslays and Field, before the Select Committee on Steam Navigation to India.*

693. You have had much experience in the manufacture of engines for steam vessels, have you not?—Yes, I have.

694. What do you consider the proper measurement and power of a steamer for a long sea voyage?—The relative proportion of power and tonnage fluctuates between two tons per horse power, and four tons per horse power, depending upon the purposes for which the vessel is intended, as well as the length of the voyage.

695. What do you say as to the measurement?—By measurement I understand tonnage. I have prepared a table which shows at one view the probable speed to be obtained by the application of engines of four different powers in vessels of the same tonnage, also the length of time for which they would be able to carry coal with each power on board. This table, if the committee desire it, I will put in.

AN APPROXIMATE TABLE, showing at one view the Tonnage of Steam Vessels, with the Power usually applied to such Vessels, the number of Days (of 24 hours) Coals they will carry, and the probable Speed per hour they will go with smaller powers and greater quantity of coal.

696. Will you explain to the committee the object of this calculation; is it a comparison of tonnage with the consumption of coals and days, and the rates of going?—It is to show about how many days' fuel steam vessels will carry with larger and with smaller engines on board, as well as the average speed to be expected from each. Such a table can only be an approximation.

697. Will you first state what you consider the proper measurement and power of a steamer to go a long sea voyage?—I should recommend a vessel of from 7 to 800 tons, having an engine of 180 or 200 horse power.

698. How long would such a vessel run, and at what rate would she go?—She would carry coal for 14 or 15 days, and have a speed, in still water, of 9 or 10 miles per hour, and would realize in all weathers, at sea, an average of 8 miles while under-weigh.

699. What is the greatest proportion in tonnage and power for a steamer going a long voyage?—The greatest propor-

tion of tonnage for vessels going long voyages may be stated at 4 tons per horse power; for short sea voyages, 3 tons per horse power; and for river vessels, as Margate or Gravesend, 2 tons per horse power.

700. What results does the power give to a vessel of the same tonnage with different powers as to the rate of going?—Great power in small vessels gives great speed, but they carry a small quantity of coal, and are soon exhausted, while larger vessels being able to carry a greater quantity of coals, work longer, and perform greater distances.

701. Then you draw this inference—the longer the voyage the less the speed?—The smaller the power, the greater capacity there is left for coal, and therefore the greater number of days' coal it would carry.

702. And the less speed?—And less speed having less power.

703. And the smaller proportion of power would of course consume less fuel in an equal time?—Exactly so.

704. Would not the greatest proportion of power consume the least fuel in equal distances?—Against winds or tides it is so; but in calms and fair winds it is not.

705. What is the greatest distance you suppose a sea-going steamer to run without changing?—The same steamer should not go more than 2,000 or 3,000 miles without a relay, or time to put the machinery in order.

706. Does that also include without taking in coals?—A voyage of 2,000 or 3,000 miles may be performed in one stage, but it would be desirable on every account to divide it and take less coal.

707. What is the greatest distance she would go without coming to a station to take in fresh coals?—The distance is limited only by the quantity of coal she can carry.

708. What is the greatest distance you think a steamer could go without taking in fresh coal?—The greatest distance I have known a steamer to perform was the *Enterprise*, on her voyage to the Cape, in which she carried 37 days' coal.

709. With continued steaming do you mean?—Yes; she steamed 34 days, and had three days' coal left.

710. Do you mean steaming day and night?—Yes.

711. Besides the coal, is it not necessary to give the engine rest?—It is; and the more frequently they can be stopped to clean and adjust, the better they will perform.

712. Then your observations must be supposed to apply to both?—Yes.

713. What is the comparison as to the duration between copper and iron boilers?—Copper boilers are found to last about seven years, without such repairs as render it necessary to take them out of the vessel, whilst iron boilers must be taken in four years.

714. Which would you prefer on the whole?—I should prefer copper for long sea voyages.

715. Is not the thickness of the me-

tal an advantage in raising steam?—The metal is of the same thickness, whether the boiler be of copper or iron.

716. The salt water does not affect copper so much as it does iron, does it?—No, it does not.

717. What is your opinion of the relative advantage of the common paddle-wheel with that of any other invention with which you are acquainted?—The common simple paddle-wheel, when the dip does not exceed one sixth of the diameter, is an excellent propeller, and scarcely admits of improvement; but when vessels are so deeply loaded that the dip exceeds this in any great degree, a wheel with feathering boards will propel faster.

718. You have fitted river boats with vibrating cylinders, have you not?—Yes.

719. What may be considered to be their principal advantage over the other?—The advantage of vibrating cylinders in river boats is, that they are more simple in their construction, lighter, and occupy less space.

720. But in point of weight and space what is the advantage?—Reduction in weight is the most important consideration in river navigation.

721. Is not the power conveyed more immediately to the crank by the oscillating cylinder?—The power is more durable [directly?] communicated from the piston rod to the crank; the engines are, as it were, suspended to two strong beams, which lie across the gunwale, and project for the support of the wheels, forming an independent frame, in which the strain of the engine is confined; the whole resting on the upright sides, the weight is more equally distributed over the whole vessel; thus partial pressure on the bottom is avoided; this admits of the vessel's being of the lightest possible construction.

722. Is not the disadvantage, that it is very difficult to keep the connecting pipes steam tight in oscillating cylinders?—As we construct that part, there is not the least difficulty.

723. Has not that been found to be the case?—Speaking of those we have made, no such difficulty exists.

724. Must there not be continual wear on the connecting pipes, from the motion of the oscillating cylinder?—Not if they are properly constructed.

725. What is the largest power upon which you have constructed those cylinders?—Two thirty-fives is the largest we have made upon this construction, and that was for a sea vessel.

726. Would you think it advisable to make them of a larger power for sea-going steamers?—The principle is exactly the same in this as if on the ordinary construction; and so far as we have tried them, work just as well, and produce the same effect in speed, and economy of fuel, as our other engines.

727. What is the advantage of weight and space?—A reduction in the weight of the engine leaves greater capacity for cargo and fuel.

728. What is the extent of the im-

provement of weight and space?—About 10 per cent.

729. One fifth of the weight and one fifth of the space do you mean?—No; about one tenth of these.

730. Is not the pipe in the fixed cylinder, which brings the steam, connected with the cylinder by means of flanges, which are secured very tight together; and in the oscillating cylinder, must not the cylinder continually move on the end of the pipe, and is the chance of becoming less steam-tight greater in the oscillating cylinder than it is in the fixed cylinder?—No; the union is effected by a stuffing-box packed with hemp, and is kept perfectly tight without the least difficulty.

731. Is it more expensive than the other?—No, they are rather cheaper.

732. Would they not be apt to be deranged in a heavy rolling sea?—We have not found that to be the case: one has been working in a cargo vessel, between Dover and London, during the last winter to the present time.

733. What is the greatest extent of time that you have had oscillating cylinders at work?—About four years and a half or five years.

734. On the sea?—No; to Richmond.

735. That is a small high pressure, is it not?—No; it is a low pressure.

736. Have you had one on the sea for the last three years and a half?—No; only during the last year.

737. Was there not a second steam-boat with an oscillating cylinder going to Richmond?—There was one to Hammer-smith last summer.

738. How did that succeed?—Very well, I believe.

739. The packet boat from Dover to Calais makes use of an engine of that kind, does it?—Yes.

740. Is that one of your manufacture?—No.

741. Is not the friction greater in the oscillating cylinder than it is in the fixed one?—No; as the number of bearings and moving parts are reduced, the friction should be reduced also, unless, indeed, it be badly constructed.

751. Have you considered the construction of the American steam raft?—I have seen a description of it.

752. Do you think highly of it?—It is certainly an ingenious method of obtaining great speed in smooth water, but its application is limited.

753. What do you think of the practicability of applying it generally?—It would not do at sea; and as it must draw more water than a single vessel, it would not do for shallow rivers.

754. The speed of it is very great, is it not?—It is so stated, and I believe it may be so, for the following reasons: the two pointed cylinders, from their form, may be made of the lightest materials, and need not be made of larger diameter than is sufficient to displace the total weight; their form offers the least resistance, and their relative position gives the required stability.

755. What do you think is the best

kind of coal for steam vessels, with respect to power and safety from spontaneous ignition?—Hartley, Elgin, Inverkeithing, Ward's Llanelly, Llangennech, and Lydney, are all esteemed good coals, and are free from the danger of spontaneous ignition.

756. What is that Scotch coal?—The three first named are Scotch coal.

757. How is the Welsh coal, do you consider, upon those points?—The Welsh coal produces very great heat, and is very effective; but the heat being confined to the fireplace more than other coal, it destroys that part of the boiler faster than the Scotch coal. The heat is more intense in the fireplace, and less is carried forward to the flues than by the other coal.

758. What is the comparison of the proportion of the Scotch coal to the English coal in its power?—I think they are much the same. We have made many experiments, and we do not find much difference.

759. The Welsh coal is considerably greater, is it?—I do not think it is. It has the advantage of not smoking.

760. Is not that because every part of the coal is consumed?—Yes.

761. No portion is carried off, must it not therefore be a coal of greater intensity in a given bulk on that account?—I cannot state that it is more powerful, or more economical, but the heat is more intense in the fireplaces.

762. Must it not, therefore be a coal of greater intensity of heat than if a portion of it were carried off?—It is not so productive in the flues. It does not carry its heat forward, it is more like the fire of a forge.

763. Then, including the expense and power, you would give a decided preference to one species of coal rather than another?—I prefer the Scotch coal.

764. On what account?—I think it injures the boilers less, and leaves less residuum.

765. What species of Welsh coal do you allude to?—Llangennech and Ward's Llanelly are Welsh coal, and are without smoke.

766. Under what circumstances does spontaneous ignition occur?—Coals which contain iron pyrites, and have become damp, are most liable to ignite.

767. What do you think of the Forest of Dean coal?—Some of the Lydney coal which we tried proved very good.

768. Do you ever use the Kilkenny coal?—No.

769. At what should you estimate the expense of such a vessel as you consider best calculated for a long sea voyage?—A vessel of 800 tons, and 200 horse power, would cost about £33,000, fitted out in the best manner, with engine and every equipment.

770. Then such a vessel as you stated at first, is that the one that you prefer?—Yes.

771. What would be the prime cost, and what the annual expense of such a vessel?—The prime cost would be about £33,000.

772. And what the annual expense?—Do you propose to include the repairs with the expenses of working?

773. Working and every thing else—keeping her up, and every thing.—How many days do you propose her to work in the year?

774. Every thing that is to keep the vessel going for as many days as she shall continue, to the end?—The annual cost of working such a vessel, including coal for steaming one third of the time, and all other expenses, would be about £7,000.

775. In computing the entire expense of a steam vessel, and annual charge, what amount should you say for capital, the sum for insurance, repairs and renewals, calculated to create the perpetuity of the property?—I think that would not be less than 25 per cent. upon the outlay.

791. By which means could you go the greatest distance, without being obliged to take in coals; by the working a small power, and at a slow rate, or by working with a great power, at a rapid rate: for instance, an engine of 100 horse power, working at ten miles per hour, or an engine of 40 horse power, working at 7 miles per hour?—In moderate weather the small power with a great quantity of coal; but against head winds a great power will go the greatest distance.

792. In the construction of a river steamer, do you prefer the flat bottom, with the raking bows, and a parabolic curve?—I think for river steamers, where the draught of water is not very limited, the form of the vessels adopted on our river to Gravesend, or Margate, are best for speed, they are sharp, dividing the water sideways; but, perhaps, in a very shallow river, the spoon-shaped bow might be best. I do not know any experiment that would directly set that matter at rest; there are different opinions upon it.

793. What construction do you think the best for steering a vessel round a point against a strong current?—I should think the sharp vessel would steer better than the spoon-shaped vessel.

807. Would it be safe and desirable to use a high pressure engine in a small vessel on a river, in order to lighten her draught?—I am not acquainted with any high pressure engine that has been quite successful in a boat yet; all the high pressure engines that I have seen are as heavy as the low pressure engines, except in some few instances of a particular kind, which are not fit for general navigation.

808. How is it on the score of safety?—The low pressure engine is, of course, much safer.

813. What do you consider to be the comparative advantage of steam navigation in seas and rivers, as to its expense, and as to its certainty?—I can speak of the certainty better than the expense; the rate is increased more than double and the time halved. I have also an abstract of sixteen voyages made between Falmouth and Corfu by sailing vessels, the mail packets, before steam packets were

established; it is the same voyage, and the average is 93 days, the steam packets giving an average of 47, which is half the time.

814. What is your opinion of the comparative advantage of the navigation in rivers and by sea in steamers, as to expense and certainty?—River navigation is less expensive, inasmuch as smaller vessels will suffice, and river voyages are performed with more certainty.

815. Suppose it were one thousand miles by river, and one thousand miles by sea, on which side is the advantage, both as to expense and certainty, both by steam?—River, certainly.

816. Suppose you have a whole space of 3,000 miles to pass by water, half of which is in one case to be performed by the river, and in the other the whole by sea, which of the two should you think preferable as to expense and certainty; which should you prefer as a permanent navigation?—Two kinds of vessels being necessary in this case, I cannot speak confidently.

817. Which should you prefer as to certainty?—I should think the certainty much the same in both cases.

818. Should you think a sea navigation as certain as a river navigation?—The Mediterranean packets show it to be very certain, for the fluctuation is only a very few days, which is very little for the whole four years.

819. On which side should you think the speed would be in favor, of the sea or the river, supposing there was a current of 3 miles in the river, and that you had 1,000 miles to go against that current, or 1,000 miles to go by sea, by which, by the river or by the sea, on an average, would you pass over in the shortest space of time?—I rather apprehend the sea.

825. You have given your opinion as to the proportionate power of tonnage to sea-going steamers: on what data do you found that opinion?—From having fitted out a great many vessels.

826. Do you mean vessels employed in the service of Government, or do you mean vessels employed for private purposes?—Both.

827. What number of persons in proportion to the register of tonnage of the steam vessel would you allow for short voyages, and what for longer?—How many it would be safe or convenient?

828. No; how many men would you wish to take to man your vessel, that is, the crew?—I think about one man to every thirty tons, including the stoker.

829. What would be the proportion of passengers, or soldiers, if you were conveying troops?—About one man to a ton, I should think, or more for a short distance.

830. You have given us the quantity of fuel of every horse power, have you not?—Yes, I have.

831. What quantity of fuel, and what description do you allow per horse power per hour?—We allow eight pounds per horse power per hour.

832. And what is that calculation founded upon; is it founded upon the

average of the consumption?—Upon the consumption, and upon experiments made at different periods with engines of our manufacture.

833. What sized cylinder, and what length of stroke, do you allow for 180 horse?—Two cylinders of 51½ inches, and 4 feet 6 stroke.

834. What would you allow for a 200 horse power?—Two cylinders 53 inches diameter, and 5 feet stroke.

835. What would you allow for a 250?—Two cylinders, 59 inches diameter, 5 feet 6 inches stroke.

836. What would you allow for a 300 horse power?—Two cylinders, 64 inches diameter, 6 feet stroke.

837. What pressure do you use in the boiler?—About four pounds.

838. And what in the cylinder?—As near the same as an open pipe will receive it.

839. And what proportion is the paddle wheel to be to the length of the stroke?—From four to five times the length of the stroke.

840. What breadth of float would you recommend?—For river navigation, the wider it is the better; for sea navigation, about one third the diameter of the wheel.

841. What length of time would an engine work without injury?—In one spell do you mean?

842. Yes.—They are frequently worked from Falmouth to Gibraltar, which is 1,100 miles, in one spell.

843. What is the greatest and the shortest length of time they take to do that distance; that is, a spell of 1,000 miles?—Eight is about the shortest, and 12 the longest.

844. How long should an engine last if well managed, without repairs?—About from 4 to 5 years.

845. What parts of the engine and boilers are most liable to accidents?—Those parts most exposed, such as the wheels; then the moving parts, cross heads, beams, &c.

846. Can duplicates of those parts be kept on board?—Yes.

847. Does it require any more engineers to manage an engine of 300 horse power, than it does to manage one of 100 horse power?—It does, but not in proportion to the increase of power.

848. In proportion to the power, is a large engine more economical than a small one?—Yes, it is rather.

849. Does it consume less coal in the same proportion?—It consumes less coal in proportion as the power increases.

850. Suppose a vessel to have 300 horse power in smooth water, or a fair wind, could you work it at the same consumption of fuel which a vessel of 200 horse power would be worked at, by throttling the valves, wire-drawing the steam, or any other mode of working the engines?—Yes, you may do so.

877. Have you ever made experiments on the combustion of wood, for the purpose of raising steam?—I have not myself made those experiments, but I am aware that such have been made.

878. Are you sufficiently acquainted

with the subject to give an answer as to the proportion of space alone that a day's consumption of wood would bear to a day's consumption of coal?—I can only state generally, that it requires three times the weight of wood to produce the same effect as coal.

885. You were speaking of the comparative advantages of river and sea navigation; would not the boilers last longer by supplying them always with fresh water?—They would, and that would be an advantage in favor of the river.

886. Are you aware of the improvement introduced into some steam vessels, to condense the steam in the pipes, without admitting the jet of water into the aperture?—I am.

887. If this were adopted and found efficacious, you would not use the salt water at all, neither for condensing nor for the boilers, would you?—No, I should not.

888. Do you think it likely that this will be brought to perfection?—I do not know; if it succeeds it will be a very great advantage.

889. Is the salt water more or less injurious to copper or to iron?—It is much less injurious to copper than to iron.

890. Is it in comparison with fresh water?—Yes.

891. If that plan which is now trying be carried into execution, will that diminish the burthen of the engine itself in the vessel?—No, it rather increases it; but it promises to reduce the quantity of coal.

892. That you find to be one of the effects to arise from the improvement, do you?—Yes, I think that would follow.

893. It would get rid of the condenser, would it?—No, it requires a larger condenser.

894. You mentioned that, as applied to sea voyages, copper would last about seven years, whereas iron would last only about four years; what would be the proportion in fresh water?—In fresh water, for steam navigation, the boilers last about seven years.

895. The iron boilers are you speaking of?—Yes; copper boilers are not used in fresh water; there is no inducement to use copper boilers in fresh water, because iron lasts so long.

896. Are copper boilers used in salt water?—Yes.

898. In preferring copper boilers to iron ones for salt water, do you make an allowance for the difference of the tenacity in copper, and the different temperature in the boiler; that copper diminishes in tenacity as heat is applied, and iron does not?—We find no difference in that respect; the copper and the iron are of the same thickness, and the question turns entirely upon their durability.

OPENING OF THE RAILROAD.—Yesterday was a great day on the new Railroad between Baltimore and Washington, being the first day of its being opened for travel all the way from the depot at Baltimore to the foot of Capitol Hill in this city.

It was a glorious sight to see four trains of cars, with each its engine, extending altogether several hundred yards in length, making their entry by this

new route, to the delight of thousands of spectators on the elevated grounds directly north of the Capitol. These cars, besides bringing back our own Mayor and Members of the Corporation, and City Guests, who went out to meet them, brought as many Ladies and Gentlemen of Baltimore as made up the whole number of about a thousand persons carried by the cars. These, accompanied by two bands of Music, after debarking, marched in procession to Gadsby's and Brown's Hotels, at both of which sumptuous and bounteous entertainment was provided, and liberally partaken of. The cars arrived at a little before one o'clock, and at four our friends from Baltimore re-embarked, and returned to their homes, without, we trust, any accident or other inconvenience than what was occasioned by the dust on the roads and streets.—[National Intelligencer.]

[From the Jersey City Gazette.]

An important case is about to be brought before the Chancellor of this State for his decision, which is deeply interesting, not only to the parties concerned, but to the travelling public generally. An information and bill have been filed in chancery, by the Attorney General and certain relators therein named, against the Trenton and New Brunswick Turnpike and the Trenton and Philadelphia Railroad Companies, praying an injunction to restrain them from converting the straight turnpike into a railroad. The Trenton Emporium says:—"The relators are large landholders along the line of the turnpike, and stockholders in the turnpike company. The injury to them, of which they complain, is—on the part of the landholders, that they sold, and the turnpike company became possessed of, the lands used in making the turnpike, for the purposes of a turnpike, as they were known and understood at the time the charter was passed, and for no other purposes whatever—that the construction of a railroad thereon is a departure from the plain terms on which the lands were sold to the company, as well as a violation of the provisions of the act incorporating the company—that this departure from the original terms and provisions under which the road was made, will seriously affect public rights, inasmuch as the turnpike is, and ought to be, a public highway, free and safe for vehicles of all descriptions, which cannot be the case if it should be converted into a railroad. On the part of the complaining stockholders, it is alleged, that the directors are squandering the money of the company for objects never contemplated by the charter—that no dividends have been paid for two years past, but that all the resources of the company are appropriated to the digging of ditches, quarrying, embanking, and laying wooden rails, to the manifest injury of the road as a turnpike, and without any sufficient authority for so doing. These are the principal facts complained of.

The legal points in the case are raised in the bill, by alleging that the monopoly are doing these things under the pretence that the principles laid down by Kent, and Webster in his first opinion, are true; the contrary of which is held by the attorney general in behalf of the state and the relators, who charge, in substance, that the legal doctrines as laid down in the irrefutable opinion of the late chancellor Williamson, are true, and ought to be sustained by the court.

"To the bill is annexed the usual affidavits by the relators, of the truth of the facts stated, accompanied by affidavits of indifferent individuals, of the digging of ditches, quarries, raising embankments, &c., in the turnpike, and that about one thousand feet of wooden rails ready for shoeing, have been laid.

"It is expected that the chancellor will appoint an early day for hearing the argument, and that prompt justice will be done both parties."

We stated a few weeks since that twelve suits had been brought by the Philadelphia and Trenton Rail Road Company against the Trenton Delaware Bridge Company, to exact twelve several penalties, of thirty dollars each, for demanding a higher rate of toll for passing the Delaware Bridge, than they are authorized to demand by their charter—viz: for charging 63 1-2 cents for a coach drawn by two horses, when their charter only authorizes them to demand 50 cents. We now learn from the Trenton Argus, that these suits were tried last week, and judgment in each were rendered for the plaintiff. There are other suits now pending against the company, and it is said more are about to be commenced.

(From the Repertory of Patent Inventions, &c.)  
**Specification of the Patent granted to JOHN SMITH, for a certain Improvement on Chisels or Instruments for cutting or dressing Stone, and certain other Substances.** Sealed December 23, 1834.

In ordinary millstone chisels, and also in chisels for cutting, dressing, or working other stone, and also for dressing cast iron, it is well known that the cutting edges quickly become worn, and consequently constantly require sharpening, which operation is performed by heating the same and forging such cutting edges to the degree of sharpness required; the operation of tempering is then to be performed; all which requires much time and judgment, and in places distant from a forge becomes a matter of considerable consequence. Now, the object of my invention is to use a thin plate of steel, properly tempered, which being supported on either side by cheeks, such steel plate, (as it becomes worn,) being capable of movement in order that a sufficient quantity for the cutting edge shall project beyond the ends of the cheeks, yet such thin steel plate, when in use, is rigidly held between the two cheeks, and prevented receding from its work by a screw, whereby the whole, when combined, will produce a strong and highly useful chisel, as will be hereafter more clearly described.

Fig. 1 represents the side view of a chisel constructed according to my invention.

Fig. 2 an edge view thereof.

Fig. 3 represents the two cheeks, which I usually construct of iron and case-harden them.

Fig. 4 is a flat view, and also an edge view of the thin steel plate which constantly supplies a cutting edge to the chisel.

Fig. 5 is a short male screw which fits the female screw formed in the cheeks of the chisel.

Fig. 6 is a small screw, with a ball or knob at the top, which screws into the upper part of the chisel when the same is intended to be used with a mallet. And it may be desirable here to remark, that when the chisel is used for dressing millstones it is affixed in a wooden handle similar to those used for ordinary chisels.

Fig. 7 is a hammer for driving the socket and also the wedge or cotter hereafter mentioned; and on the end of the handle is formed a key for screwing up the internal screw, fig. 5, in order to press forward and support the steel blade as it becomes worn.

Having thus generally referred to the figures in the drawing, the construction of the parts there shown will be evident to any competent workmen, I will enter shortly into the manner of putting the same together, first observing that in each of the figures shown in the drawing the same letters of reference indicate similar parts. *a* and *b* are the two cheeks which constitute the main frame of the chisel; these cheeks go together by means of the mortice, *c*, and the studs, *e*, *e*, which latter into recesses formed in the cheek, *b*, as will be evident on inspecting the various figures. The thin steel plate is next inserted between the two cheeks, *a*, and *b*, the socket, *f*, is then to be placed on the end of the cheeks of the chisel, which being wedge form, the driving up of the socket will cause the same to bind more closely on the steel plate between them, and hold the same rigidly, and thus prevent lateral spring. It should be remarked, that on the cheek, *a*, is formed a groove, and in the socket, *f*, are two openings through which the wedge or cotter, *g*, is inserted and driven, by which the whole

of the parts are securely held together. The screw, fig. 5, is to be screwed up within the female screw, in order to press against the other end of the steel plate, to assist in preventing its receding from its work. In using a chisel so constructed, the steel plate which constitutes the cutting edge will only require occasionally to be rubbed or ground on a stone in order to improve the sharpness, and as the same becomes worn away, in order to project a further quantity beyond the end of the cheeks, *a*, *b*, it will only be necessary to remove the wedge or cotter, *g*, and slide down the socket by giving it a few blows on the knob, *i*, the screw, fig. 5, may then be screwed up by the key on the handle of the hammer (fig. 7), which will project a further quantity of the steel plate below the ends of the cheeks, and such will be the case till the screw, fig. 5, arrives at the end of the female screw, when there will require a fresh steel plate to be inserted. At each time of projecting the steel plate the socket is again to be driven up, and the cotter or wedge inserted as before described.

Having thus described the nature of my invention, and the manner of carrying the same into effect, I would have it understood that I do not claim any of the parts separately of which the same is composed, but I do hereby declare that I confine my claim of invention to the combining of the various parts as above described into a chisel for cutting or dressing stone, and certain other substances, whereby I am enabled to use a thin plate of steel as the cutting edge, which may from time to time, as it becomes worn, be projected forward and offer fresh quantities for use, and yet, when in use, be rigidly held between the two cheeks, and prevented receding by the male screw, as above described.

Enrolled Feb. 23, 1835.

(From the London Mechanics' Magazine.)  
**HUNTER'S STONE-PLANING MACHINE.**

In March last, a patent was granted to Mr. James Hunter, of Leys Mill, Arbroath, "for certain improvements in the art of cutting, or what is commonly called facing and dressing certain kinds of stone." The specification of Mr. Hunter's method has not yet been enrolled; but from a Report, with a copy of which we have been favored, made to the proprietor of the Leys Mill Quarries, (W. F. L. Carnegie, Esq.,) by Messrs. Carmichael and Kerr, engineers, of Dundee, who were invited to see the method in actual operation at these quarries, and to verify the results, it appears to be immensely superior to any other hitherto devised. Mr. Hunter has seemingly realized that great desideratum, a power-machine for the cutting and dressing of stone, capable of withstanding the extraordinary friction to which it must necessarily be subjected. The despatch with which immense blocks of stone are cut up and dressed, by Mr. Hunter's apparatus, is prodigious; yet the cost of tools is next to nothing—"only a half-pennyworth of steel for every hundred feet of planed surface!"

*Report of Mr. Charles Carmichael and Mr. John Kerr, Engineers, Dundee, on the power of Mr. James Hunter's Stone-planing Machine.*

Sir,—Agreeably to your desire, we have visited Leys Mill Quarries, and attended minutely to the performance of the stone-planing machines. These machines do their work most effectually, as the following experiments, which we witnessed, will testify.

*Experiment First.*

We went to one of the machines that had six stones laid on the bench, one of which was planed, and the second begun to be operated upon; while this was doing, we took the dimensions of the other four stones, viz.:

Number of Stones.	Length of Stones.	Breadth of Stones.	Thickness of Stones.	Finished Thickness.	Quantity taken off.
1	5 3	2 6	3 1/2	2 1/2	1
2	5 0	2 8	3	2 1/2	5/8
3	5 6	2 6	6	4 1/2	1 1/2
4	4 0	2 3	4	2 1/2	1 1/2

The average thicknesses of the above stones are given, but many parts of them were much more than the thickness stated. One of the broad finishing tools was blunted ere the experiment began, and was changed when No. 2 was in the operation of being planed. No. 3 was a very hard stone, and was what is technically called yolk, in planing which one of the roughing tools broke at the point; still it wrought out the stone, and was then replaced. A splinter came off the face of the last stone, when about half finished, which was another cause of delay, as they had to go over it again; but, notwithstanding the delay occasioned by the breaking of one tool, by another being changed, and by having to go over the one half of the last stone twice, yet the time altogether was forty-five minutes, being at the rate of sixty-five superficial feet per hour.

*Experiment Second (same machine.)*

Five stones were now put on the planing machine, of the following dimensions, viz.:

Number of Stones.	Length of Stones.	Breadth of Stones.	Thickness of Stones.	Finished Thickness.	Quantity taken off.
1	4 3	2 2	4 1/2	2 1/2	2
2	3 9	1 10	4 1/2	3 1/2	1 1/2
3	3 4	2 8	6	4	2
4	3 6	2 0	6 1/2	4 1/2	1 1/2
5	3 8	3 6	5 1/2	4 1/2	1

These stones were planed in forty-two minutes.

The above stones were taken from the quarries without selection, and the men that were working the machine were not informed of the object of our visit. Experiment first began at half-past twelve o'clock, noon, and experiment second was concluded at nine minutes past two; thus leaving twelve minutes for cleaning and reloading the bench of the machine. Had all the stones been 5 1/2 feet long, they would have been planed in exactly the same time, for the machine travels the distance for that length; so that nearly sixty-seven feet of surface would have been planed in forty-two minutes.

The stones, as they come from the

machine, are remarkably smooth and straight on the face; and were it not for the shade left by the tools, we would be apt to think them polished, as they feel as smooth as a polished stone.

We were told by the foreman, that during the last week there was planed\* 4,400 superficial feet, more than half of which was planed on both sides, (indeed more than half of all the stone that leave the quarry are planed on both sides,) by four machines. We saw the pay-list for the week: the amount was £6 1 6

Add blacksmith for dressing and grinding tools, 12 0

£6 13 6

We were further informed by the manager, that during the last summer there were upwards of 100,000 feet of pavement planed by four machines; and there was one thing that struck us most forcibly, which is the small degree of wear on the tools. Three shillings a week, or sixpence per day, is the cost of the labor for dressing and grinding the tools of one machine; and the whole consumption of steel during the last year was under a hundred weight, so that, if we measure both sides of those stones that were actually planed on the two sides, it will be seen a pound of steel will plane 1,500 feet, or about a half-pennyworth of steel for every 100 feet of planed surfaces.

There are now five machines working in the quarry, wrought by a steam engine of six-horse power, the steam cylinder of which is sixteen inches diameter, stroke two feet. Besides the machines, the engine has to work two inclined planes, one of which is for dragging up the pavement from the quarry to the machines; the distance on the incline 48 feet, ascent 1 foot in 5; average quantity about thirty tons per day of ten hours.

The second incline is for dragging up the rubbish from the quarry to the place where it is deposited; distance 87 feet, ascent 1 foot in 4; quantity from 50 to 60 tons per day of ten hours.

The above shows what the engine is actually doing; and we have no hesitation in saying that the engine would work eight machines besides the inclines without being overloaded; and our opinion is that a machine, on the average, is not much more than one-half-horse power.

We are, Sir, your most obt<sup>s</sup> serv<sup>ts</sup>,

C. CARMICHAEL,  
JOHN KERR.

To W. F. L. Carnegie, Esq., Kimblethmont, Arbroath.

*Note by Mr. Carnegie.*

To explain the difference which is apparent between the quantities of planed stone, which, according to the statement of the engineers, might be produced in a given time by the machines, and the quantity stated to them as in one week actually sent to market, it is necessary to remark,—1st, That it is found in practice to be cheaper to dress the stones by the machine in the rough state and shapeless form in which they are taken from the quarry, and to square them by hand

\* See subjoined Note by Mr. Carnegie, on this point.

afterwards, than to follow the opposite course, as is done where the whole work has to be performed by hand; thus a great quantity of work measured by the engineers, but not available in the market, is nearly lost. 2d, A considerable quantity is required to be dressed over twice on one side, or on both sides, according to circumstances; thus the stones, No. 3, in Exp. 1, and Nos. 2, 3, 4, 5, in Exp. 2, being too thick, were redressed on the under side to suit the market. 3d, The quarry does not always afford stones of a size to fill the benches, when much power is lost, as the machine has to traverse the whole width. 4th, Other circumstances, (such as bad weather, &c. &c.,) which will readily present themselves to the minds of those conversant in these matters, always occur to prevent general results from attaining the extreme limit, which may be calculated as possible from the data of a short experiment. Mr. L. C. having been present, can confidently testify as to the correctness and impartiality with which these experiments were conducted, and to the truth of the information furnished to the engineers, by those in his employment.

[From the Journal of the Franklin Institute.]

*Abstract of the Specification of a Patent for a Machine for Moulding Bricks.*  
Granted to WILLIAM C. GRIMES, of York, in the county of York, in the State of Pennsylvania, Dec. 2d, 1834.

This machine is constructed upon the following general principles. A wheel is affixed horizontally to, and revolves with, an upright shaft, the latter being properly supported above and below by a suitable step and box, in which its gudgeons turn. The moulds in which the bricks are to be formed are placed around and upon the face, or upper side, of the wheel, near its periphery; these may stand in the direction of radii from the centre of the wheel, or otherwise. Two or more moulds may be united or connected together. A hopper, or trough, of sufficient capacity, is placed in an inclined position, with its lower end over one or more of the moulds at a time, as they pass under it. This hopper is to contain the tempered clay of which the bricks are to be made, and though that part of the bottom of it which projects over the mould, or moulds, an opening, or openings, are made of the length and width of a brick, through which the clay is to descend into the moulds. The motion of the wheels is not to be continuous, but intermitting; while it is at rest, a mould is immediately beneath the opening in the bottom of the hopper, or trough, and the clay is then forced by a piston down into it; the piston then rises, and the wheel moves, and the moulds are thus filled in succession. As the filled moulds pass round upon the wheel, they are removed, and replaced by empty ones.

It is manifest that two or more moulds may be filled at the same time, by the use of two or more openings and pistons, and the employment of such other devices as may thereby be rendered ne-

cessary, sufficient power being applied for that purpose.

The number of moulds will depend upon the diameter of the wheel, which will admit of considerable variation, but from four to six feet I think the most convenient.

The moulds must be slightly attached to the face of the wheel, which may be done in various ways, the following being among the best. From the under side of the moulds project two dowel pins, which fit into corresponding holes in the face of the wheel, by which means the moulds are kept from any lateral or horizontal movement. The dowel pins should be short, so that the moulds may be readily disengaged from the wheel. The holes for the pins, or dowels, in the face of the wheel, should be pierced through it, so as to prevent them from being filled, or choked with dirt, &c.

Two or more moulds may be united in one frame, as is usual in brick moulds. The frames of the moulds are inclined from each other, like key-stones, so as to stand as radii from the centre of the wheel, thus forming the proper arch or curvature around the wheel, and their upper surfaces should form a true plane. Each frame of moulds has a thin plate, or board, which is equal in length and breadth to its corresponding frame, and forms the bottom or bed of the moulds. The aforesaid dowel pins pass loosely through holes made for the purpose in this plate; the latter not being otherwise fastened to the moulds, its use will be apparent to any one acquainted with the usual mode of moulding bricks.

The machine may receive its motion by a strap, carried around the fly-wheel, and over a drum, or pulley, which last may be driven by any competent power; or the machine may receive its motion by a crank attached to the fly-wheel shaft, or in any other convenient mode.

I do not mean to confine myself to the particular form or arrangement of the parts as before specified, but to vary them as experience or convenience may dictate, whilst the general principle remains unchanged.

What I claim as new, and as my invention, and for which I ask letters patent, is, 1st. The moulding of brick upon, or in moulds upon, the face of a revolving horizontal wheel, disk, or rim, constructed and acting upon the principle herein specified.

2d. The manner of forcing the clay into the moulds, by the combined action of a feeder and piston.

3d. The general construction and combination of the respective parts of the above described machine, from which general combination it derives that character by which it will be readily distinguished, by any competent machinist, from the various machines for moulding bricks already in use.

And I do hereby declare that I do not intend to claim as my invention, the piston, cranks, hopper, or any other part of the said machine, taken separately and individually, as these may constitute the

elements of other machines; but, as aforesaid, the construction and combination of these parts upon the principle by me devised, and herein fully exemplified.

WILLIAM C. GRIMES.

The foregoing comprises about one-half of the specification, the remainder generally referring to the drawings. The same remark will apply to the next patent, and also to those for making nails. The machines manifest much ingenuity, and an account of their performance, when completed, has been promised, which, if satisfactory, will appear in the Journal. —[Ed. J. F. I.]

*Abstract of the Specification of a Patent for a Machine for Pressing Bricks.*

Granted to WILLIAM C. GRIMES, of York, York county, Pennsylvania, December 2d, 1834.

The general principle of the construction and operation of this machine is briefly as follows.

Upon a vertical shaft, or spindle, is fixed a wheel, disk, or rim, of sufficient size, which is to revolve horizontally. In the upper face of this wheel are a number of holes, or mortises, which are the moulds in which the bricks are to be pressed. The bottoms of these moulds are not a fixed portion of the moulding wheel, but are the upper faces of movable pistons, that slide up and down in the moulds, as the wheel revolves. The rods, or posts, which support and guide the pistons, descending vertically from them. The lower ends of the piston rods, or posts, slide round as the wheel revolves, upon a circular horizontal platform, or rim, or rather upon two platforms, one-half of the circle, or thereabouts, being elevated above the other about two or three inches. When the pistons rest upon this elevated portion of the circular rim, or platform, their upper faces are flush with, or above, the upper surface of the wheel; hence the bricks which have been pressed, being thus raised, can be removed with facility; while upon the opposite side of the wheel, the pistons upon the lower portions of the rim have their upper surfaces sunk down within the moulds, leaving cavities into which the bricks are dropped, as the pistons are depressed, the motion of the wheel, which is intermitting, not being too rapid for that purpose.

Just before the pistons rise on to the elevated portion of the circular rim, they pass under the short end of a strong iron lever, which projects over the face of the horizontal moulding wheel, far enough to cover the moulds as they pass under it. The lever receives a continuous motion from a crank and shackle bar, the latter being jointed to the opposite, or long end, of the lever. The crank is regulated and assisted by a heavy fly-wheel, in passing that point in which there is the greatest resistance to its motion.

While a brick is being pressed by the short end of the lever, the moulding wheel is at rest, as it receives its motion by a pall, or movable hand, that has a vibratory or reciprocating motion, which it receives

from a crank fixed for that purpose on to the end of the fly-wheel shaft.

The horizontal moulding wheel may be of iron, and cast in one entire piece, of such thickness as may be necessary to its strength, the requisite depth of the moulds being formed by a flanch, rim, or projection, standing out upon the face of the wheel, the said rim, or flanch, making the sides and ends of the moulds. The moulds being in a circle, are placed as near to the periphery of the wheel as a proper thickness of metal will allow; the inner ends of the moulds may approach very near to each other, leaving only sufficient strength of metal between them; hence it may be seen that the number of moulds in the face of the wheel will depend entirely upon its diameter, which may be very much varied, but from three to six feet I think the most suitable.

The moulding wheel, pistons, horizontal rim, and fly-wheel, should consist of cast iron, and, in fact, the whole machine should be made of metal.

Motion may be given to the machine by a strap, carried round the fly-wheel, or by the crank attached to the end of the fly-wheel shaft, which may project beyond its bearing for that purpose.

I do not mean to confine myself to the particular form and arrangement of the parts as before specified, but to vary them as experience or convenience may dictate, whilst the general principle remains unchanged.

What I claim as new, and as my invention, in the above described machine for pressing brick, and for which I ask letters patent, is—

1st. The revolving horizontal wheel of moulds, constructed in the manner, or upon the principle, herein described, in which the processes of putting in, pressing, and removing the bricks from the moulds, are all done at one and the same time.

2d. I also claim the revolving pistons, as connected with the revolving moulds, and operating in the manner, or upon the principle, set forth in the foregoing specification.

3d. I also claim the employment of the stationary rim with a double platform, for raising and depressing the pistons, as before described.

4th. I also claim the scolloped rim, or flanch, for the purposes hereinbefore set forth.

5th. I also claim the pressing of brick by means of a lever, operating, and operated upon, as herein shown.

6th. I also claim the general construction and combination of the respective parts of the above described machine, from which general combination it derives that character by which any competent machinist will readily distinguish it from any of the brick pressing machines previously in use. But I do not claim the pistons, fly-wheel, shafts, or any other part, taken individually, as these may constitute the elements of other machines; but, as aforesaid, the construction and combination of these parts upon the principle by me devised, and herein fully exemplified.

WILLIAM C. GRIMES.

AGRICULTURE, &c.

[From the Maine Farmer.]

**NORTHERN SHEPHERD.**—The book lately published by the Kennebec County Agricultural Society, with this title, contains much valuable matter, and particularly in those parts of it which treat of the management and diseases of sheep, with the cures of the same.

As this work is before the public under the authority of the Agricultural Society, whatever it contains, which may tend to misdirect public opinion, should be corrected. The intention of the subscriber is to confine himself to the correction of a very mistaken view of the Dishley breed of sheep, compared with the Merino breed.

The Dishley breed of sheep has been introduced into this country at a great expense, and has been highly approved of in Pennsylvania and Massachusetts, and should not therefore be hastily condemned.

With due deference to those of the Committee who prepared this comparison, it does appear from the Vote of the Society, that its object was (through its Committee) to ascertain "*the best breeds of sheep and the mode of improving them.*" Would it not then have been better, and more consistent with this vote, to have described the character and qualities of each breed noticed, and to have left it to the judgment of individuals to make their own selection. The course the Committee have taken tends to depreciate a breed of sheep in high estimation in the first agricultural country in the world, and to check important experiments which might prove beneficial to this country. It is very remarkable that the British depend almost entirely on the importation of Merino wool for the manufacture of the finest broadcloths, and give their attention to other breeds which are more profitable.

It is well known that the rage for Merino sheep had nearly swept the country of what was called the "native or common breed." Aware of the consequences, the subscriber pursued a course that would secure to the farmers a breed better suited for domestic use than the Merino.

Having previously sold his Merino flock, he bought of Col. Jacques, of Charlestown, a ram and ewe lamb of the Dishley breed, with long and fine wool, and selected twenty ewes of the Merino breed, intending by this cross to improve the *shape and constitution of the Merino breed of sheep*, and add to the fineness of the wool of the Dishley.

The following facts will show what benefits have been derived from this cross, and will prove that the Merino breed of sheep will not compare with the Dishley for *profits*, notwithstanding the Merino wool is finer.

In comparing the few sales of the Dishley and its cross, with the prices of the *well washed* Merino wool, there is no great difference.

Col. Green, of Winslow, had an offer of 55 cts. per lb. for the wool of his pure flock.

In 1831, the wool from this cross was

sold for 60 cents, when well washed Merino wool sold from 60 to 65 cents.

The purchase of such wool by Mr. S. C. Whittier averaged 62½.

In 1833, from the same flock with the sales of 1831, the wool was sold for 41½ cents per lb., and well washed Merino wool on the sheep's back sold for 45½ cents at the same date.

Thus far the value. It is proposed now to furnish the evidence of the greater quantity of wool from the Dishley and the cross of it, than from the Merino.

Col. Reuben Green had a Dishley buck weighing, in health, 300 lbs., which gave of wool at one shearing 8 lbs.; 3 ewes gave 18 lbs.

Joseph Pillsbury, Esq., on the Thorndike farm in Jackson, has under his care 1000 sheep, whole or in part Saxon, which on the average yield to the fleece 3 lbs.

Dr. Bates, of Norridgwood, has a flock of 52 Merino and some half blood Saxon and Merino. The average weight of a fleece, 3½ lbs.

Mr. Allen Lambard, of Augusta, has a flock of 130 Merinos, part Saxon. The average weight of a fleece in his flock, 3 lbs.

Mr. Moses Taber has a flock of Merinos mixed with the Saxon. Before he had a buck of the mixed breed he has sheared from rams of the Saxon breed from 6 to 10 lbs.; no average of his flock.

Mr. S. C. Whittier has made extensive purchases of Merino wool, and the average of the fleeces, well washed on the sheep's back, does not exceed 2½ lbs.

Dutchess County, New-York. This county furnishes the largest quantity of the best quality of Merino wool. From a source that may be relied on, in very extensive sales, the average weight of a fleece of well washed wool on the sheep's back does not exceed 2½ lbs, with a loss in cleansing of about 30 per cent.

The Northern Shepherd, page 128, states the average weight of Merino fleeces at 3½ lbs.

This weight of 3½ lbs. as an average, exceeds the weights stated from various sources, and ought not to be considered as the average to be used in the comparison between the Merino and the Dishley with its cross. It is not intended to dispute the fact, that the writer of the note had himself or knew of some sheep that gave this average weight of 3½ lbs., but it is a well known fact that *weight may be added* to a fleece, through an increase of yolk, by leaving the sheep 15 or 20 days after washing before they are sheared. This will at once account for the excess in weight over all other flocks mentioned. However this may serve the sellers, it is surely injurious to the purchaser, who has to cleanse the wool (of the yolk) before it is manufactured, at a loss of 30 per cent.

It will be fair to consider the 2½ as the fair average, it being the result of extensive purchases made by one individual in our county, and is proper to use in the comparison. The weight of the average, after well washing and without cleansing, is per fleece 2½.

Of the mixed breed the following facts

are furnished. Mr. R. C. Rogers, of Ripley, Somerset county, had a buck of this breed about 6 years since. For 6 years the fleece averaged per annum 7 lbs. At the time he took this buck, his flock yielded 2½ lbs. on the average, and the average now is 4 lbs.

David Webster, of Rome, had a buck of this breed in 1830. The fleece, after it was well washed, weighed 7½ lbs. In 1833, after the fleeces were washed, the average weight of the same was 4 lbs.

Edmund Parker, of Norridgwood, had a buck of this breed in 1830—no weight of fleece. In 1831, 11 lambs were selected, which were sheared August 4, 1831—weight of wool 21 lbs. 14 oz.

In 1832, at the usual time of shearing, and after they were well washed, an average fleece was taken, and its weight was 5 lbs.

4 bucks were sent to Dover, Penobscot county. Several of the fleeces of the lambs, from this cross with the common sheep, after washing weighed 6 lbs. and a Saxon lamb 6½.

Col. R. Green, of Winslow, from 6 half blood lambs had 38½ lbs.

Mr. Moses Taber's largest fleeces from this mixed Merino 6 lbs. From wethers of the same cross from 4 to 5 lbs. It should be noticed here that the wool of this breed, when well washed, is fit for the manufacturer without cleansing.

The result of the preceding is, that the fair average of the Merino fleece is 2½ lbs. The fair weight of bucks of the mixed breed is 7 lbs. The average may be about 6 lbs.

The average of fleeces from this mixed breed with the Merino and common sheep is from 4 to 5 lbs.

The public must decide how far the wool of the mixed breed exceeds in weight the wool of the Merino, and whether the *small difference* in value in favor of the *Merino wool* will make up the *great difference of weight* in favor of the *mixed breed*.

**Mutton.** The mutton from the Merino sheep is in no estimation. The lambs and wethers of the mixed breed afford the *best meat that has been in the market*.

Mr. Joseph Howland killed a wether, the 4 quarters weighed 76 lbs. and in his opinion it was the best of mutton.

The subscriber killed a wether, the 4 quarters weighed 60 lbs. The flesh was marbled with fat, and as well mixed as in a fat ox. I sold a hind quarter for 8 cents per lb. which was pronounced by the best judges, who partook of it, the best they ever tasted—juicy and high flavored.

This article, already lengthy, would be too long if further details were furnished from communications on hand. It may however be stated, from the experience of those who have the mixed, that the ewes are *better mothers*, will keep in better order on coarse food in winter and in poorer pastures in summer. That they have a remarkable disposition to fatten, and to have this fat in the fleshy parts, and that the lambs are fat and well grown early in the season.

As the Committee have omitted to

notice the qualities that constitute a perfect sheep, and which notice would have been useful to the farmer in the choice of his flock, the subscriber, for the farmer's benefit, offers two extracts, one from a valuable English work, entitled "The Complete System of Husbandry," by R. W. Dickinson, M. D., in 2 volumes quarto. The other is taken from a communication made to the Pennsylvania Agricultural Society, entitled "Hints for American Husbandmen," &c. The first of these gives a decided preference to the Dishley breed of sheep over all other long woolled sheep. There is a table giving the comparative value of 16 different breeds of sheep. No. 1 is the Dishley—No. 16 is the Merino or Spanish,—and the latter is the only breed in the list where there is no estimate made of it for mutton. A two year old wether gave 8 lbs. of wool, and the four quarters weighed 100 lbs. The extract follows:

"The advantage of this Dishley breed consists in its producing a better profit to farmers, in proportion to the quantity of food consumed, than most others; in being more perfectly formed, and consequently more disposed to fat quickly; in containing a much larger proportion of meat to the weight of bone; in thriving well on such pastures as would not support other sorts of the same size; in being capable of being kept or fattened in larger proportion to the acre than other breeds of the same size of carcass; in the wool being more valuable, though less in quantity, than the other combing woolled sheep, such as Lincoln and Teeswater; in being ready for the butcher in the early part of Spring instead of the Autumn. They usually have their lambs in proportion of  $\frac{1}{3}$  of the ewes; to which may be added, they are peaceable feeders in summer, and hearty feeders without waste of food in winter."

An extract from the "Hints for Husbandmen," &c.: "There is no mistake more prevalent, and more egregious, than that which ascribes excellence to great size. Unless it be had easily and at comparatively small expense, large size does not more determine the extent of usefulness in the quadruped than in the man. Weight is not always ascertained by size—it is ascertained more by compactness and squareness in certain parts, with rotundity of the barrel, than by mere extension of the frame. If the hind quarters be long, deep and wide—the shoulders be placed well back—the breast be ample—the brisket be protruded—the back be broad—the loins wide—the girth behind the fore legs and over the chine be large,—the animal must possess not merely the frame which weighs most, but the form which carries most weight in the valuable parts, and affording sufficient room for the action of the lungs; without which, health and thrift can be seldom found. Some animals have good forms, but are "shelly," as it is technically termed, conveying the idea of the absence of the due quantity of flesh. Some breeds produce too much fat in proportion to flesh; those which carry comparatively a large quantity of flesh "marbled when ripe," with the propensity to become fat at an early age, and in the shortest time, are those best

fitted for grazing purposes. The quantity and quality of the wool is a matter of serious importance, when the value of sheep is to be determined. I do not mean by quality, the fineness of the fibre alone, nor do I mean to confine the remark to sheep whose wool is of the finest sort. The filaments of combing wool should part readily—those of fine wool should be soft and elastic, as if it had been frizzled. The mere fineness of the fibre, or length of the staple, is not the only test of excellence: a diseased or half starved sheep produces fine wool, but not an elastic nor useful material. The sheep which produce the finest fleeces are not necessarily the best to form a breeding flock. If their constitutions be not good, if their forms be bad, the secretion of yolk, which is essential for the support of the fleece, must be small; the offspring, consequently, will be a degenerate race. Thus in selecting Merinos, regard should be given to their forms, even in those parts of the country where the demand for the carcass is so small as to make mutton of little value."

I believe it was in 1831 that Mr. Sanford Howard bought some ewes, making his "selection for the carcass, and not for the fleece. With the exception of one, they had very little Merino with them, and the fleeces did not weigh more on an average than 3 lbs." These ewes were crossed with Col. Green's Dishley buck the past season and with mine since. The result follows:

1 3 year old ewe, $\frac{1}{2}$ blood, from C. Green:	54
1 2 do. weather, $\frac{1}{2}$ do. C. V.	5
1 1 do. ewe, $\frac{1}{2}$ do.	44
1 1 do. buck, $\frac{1}{2}$ do.	44
1 2 do. ewe, $\frac{1}{2}$ do.	44
1 1 do. weather, $\frac{1}{2}$ do.	52
1 1 do. buck, $\frac{1}{2}$ do.	42

334

or 4 lbs. 124 oz. to the fleece on the average.

The 3 year old  $\frac{1}{2}$  Dishley gave 184 of wool in three years. Mr. Roach's communication is a valuable article, and fixes the value of the South Down sheep.

Yours, CH'S. VAUGHAN.

[From the Cultivator.]

THE GOOSEBERRY is among our choicest garden fruits, and is one of the earliest species which is fit for the table. But in many locations it is subject to mildew, which not only blights the fruit, but the anticipations of the cultivator. Mildew, according to Darwin, is a plant of the fungus kind, which vegetates without light, or change of air, in the same manner as the generality of mushrooms; and penetrates with its roots the vessels or plants to which it adheres. Wylich says it is a topical disease, only to be cured by a topical remedy. We have heard and seen somewhat ourselves of the effects of topical remedies, in which lime, salt, or sulphur, have constituted the preventive or cure of this disease, not only upon the gooseberry, but upon the grape, wheat, &c.

In the grape houses about Boston, and in our own grape house, sulphur is efficaciously employed in its dry state, dusted upon the young fruit, to prevent mildew, or to check it where it has already appeared. Here neither winds or rain oc-

cur to wash or blow it off; and one or two applications suffice for the season. It may be applied out doors in a liquid form, by first mixing the sulphur with milk, with which it incorporates—and then diluting freely with water, sprinkle it upon the leaves and fruit with a white-wash or other brush.

A weak brine, of salt, scattered about the roots of the gooseberry and grape, in May, is said to operate as a preventive. Before we were aware of it, we perceived our gooseberry crop affected with mildew, when the fruit was about the size of peas. We immediately applied a weak brine, and three days afterwards dusted the bushes with lime. The disease was checked, and the berries have continued to swell, and appear healthy. Whether the salt or lime were separately or jointly beneficial, we are unable to say; but the remedy seems to have proved effectual. In the application of either of these substances care must be taken not to apply them in excess, lest they should destroy the plant as well as its parasite. Salt is best applied to vegetation in a liquid form, as it is then more equally distributed. Lord Manners applied it with great success, in the proportion of one ounce of salt to a gallon of water. Two ounces to a gallon proved hurtful to vegetation, but the second year the herbage where it was applied was abundant. All the land on the coast is treated with sea water in China and Hindostan. The utility of salt in preventing or destroying mildew has been announced by the Rev. E. Cartwright, [of London, as a discovery of great importance to agriculture. He declares it to be an absolute remedy for the mildew in wheat. His directions are: take "salt one part, water eight; with this mixture let the diseased grain be sprinkled; in three or four days the mildew will vanish, leaving only a discoloration on the straw where it had dried off. Two hogheads of the mixture will suffice for an acre. The best mode of applying it is with a white-wash brush, having a tin collar, made water tight, to prevent the mixture dripping down the operator's arm, and running to waste. The operator having a pail of the mixture in one hand, with the other dips the brush into it, and makes his regular casts as when sowing broadcast; in this way he will readily go over ten acres a day."

T. A. Stoughtenburgh, Esq., of Johnstown, has an east and a west high tight fence to his garden. His gooseberries on the east fence, he informs us, which do not get the morning sun, have been uniformly free from mildew; while those on the west fence, the soil at both being similar, are covered and spoilt by mildew. This has happened for years. In the compact part of Albany, in the small enclosures, excluded by buildings from the morning sun, the gooseberry is seldom affected with mildew.

THE CURRANT, like the gooseberry, should be in every farmer's garden. The fruit of the red and white varieties is nutritive and pleasant, and affords in

many ways nice dishes for the table. Like the gooseberry it is propagated by cuttings, and requires no great space or labor to make it profitable in the family, and for the market.

**Propagation.**—Take thrifty, well ripened shoots of the preceding season's growth, and cut them twelve to eighteen inches in length, and if it is desired to make them trees, or to grow them on a single stem, gouge out all the eyes with a sharp knife, except three or four upon the upper extremity, which are destined to form the branches. Cut the lower end square at a bud; it will sooner granulate, and throw out roots; and when planted insert two thirds of the cutting in well dug ground. The cuttings are best when taken off in autumn, soon after the leaves fall. They may be put out then, or, what is better, kept till spring, in a cellar, or buried in the ground. Thus every man may procure cuttings in autumn or winter to be planted in spring. They may be planted where they are to stand, or in a nursery bed, to be removed after one or two years. They may be planted in rows ten feet apart, and four feet in the rows.

The culture consists in digging the ground about the bushes in the spring, keeping down weeds, thinning the wood, and cutting in the long shoots.

The fruit may be used for culinary purposes while green, and in its ripe state is converted into wine, jelly, and is used extensively, in various ways, for the table, with other food, in which forms it is gently laxative, emollient, and sometimes anodyne. The jelly is grateful and cooling in fevers, and no less so as a conserve at table; and the wine affords an excellent summer drink, especially with the addition of water. Directions for making the jelly and wine will be found annexed.

**Sorts.**—There are two varieties of both red and white, termed the common and Dutch kinds, the latter growing on lower bushes, and affording larger fruit than the common kind. The Champaign is another kind, distinguished principally by its pale color. Mr. K. has produced a sweet kind, not yet introduced into our culture.

**"TO MAKE CURRANT JELLY.**—Take the juice of red currants, 1 lb.; sugar, 6 oz. Boil down. Or,

Take the juice of red currants and white sugar, equal quantities; stir the mixture gently and smoothly for three hours; put it into glasses, and in three days it will concreate into a firm jelly."

**FOR MAKING CURRANT WINE** numerous methods have been published. The juice of the currant consists, principally, of water, saccharine matter, and vegetable mucilage. Its conversion into wine is effected by what is termed the vinous and spirituous fermentations, which transform the saccharine matter into alcohol. If the must, or expressed juice, is deficient in saccharine matter, the fermented liquor will be weak and vapid, and run into the acetous, or vinegar, and sometimes into the putrid fermentation. Hence the practice

of adding sugar to the must, to give it body, &c. The more violent the spirituous fermentation, the more the strength of the liquor will be dissipated; and therefore the process should progress as slowly as possible, and under a temperature not exceeding 70°. The vinous and spirituous fermentations not only convert the sugar into spirits, but they separate the mucilage, or yeast, from the liquor, in a great measure, which latter then becomes clear and transparent. If the fermentation, in wine or cider, is checked, by natural or artificial means, before the saccharine matter is converted into spirits, the liquor remains proportionably sweet; but when the conversion is complete, the product is what is termed a dry liquor. If the mucilage is left in the cask after it has performed its office, it is apt to commingle again with the liquor, render it turbid, and induce, under a warm temperature, the acetous fermentation. Hence the practice, in some cases, of conducting the vinous fermentation in open vessels, and of then separating it from the scum and lees; and in other cases, of racking it off, before the action of summer heats upon it. We shall give directions for making wine in both these modes. The first is from the American Philosophical Transactions, and the latter from our friend Judge Patterson, of Columbia, who successfully adopted it for many years. For ourselves, we prefer the latter mode, though we think the brandy superfluous, where 80 lbs. sugar are employed in the fabrication of a barrel.

**First mode.**—Gather the currants when they are fully ripe, and dry; break them in a tub or vat; then press and measure the juice, to each gallon of which add two gallons of water, and to each gallon of the mixture put 2 1-2 lbs. sugar; agitate the whole till the sugar is dissolved, when it may be barrelled. The juice should not be left to stand during the night, as the fermentation ought not to take place till all the ingredients are compounded. Lay the bung lightly on the hole, to prevent flies, &c., creeping in, and in three weeks bung up, leaving only the vent-hole till it has fully done working, which will be about the latter end of October. Rack into a clean cask the spring following. For a barrel of 28 gallons will be required,

8 gallons currant juice,  
16 gallons water,  
4 gallons sugar, or 60 lbs.

28

**Second mode,**—in which the vinous fermentation is managed in an open vessel. Pick and press the currants as before, and add two gallons of water to one of juice, and 80 lbs. of sugar to a barrel of 32 gallons. Stir well, and cover the must, in an open vessel, with a linen cloth; place it where the temperature is from 60° to 70°, and next day skim off the impurities which rise to the surface, and stir again the liquor. Repeat the operation as long as the scum rises. Then barrel, rejecting the lees, adding 2 1-2 gallons good brandy, and bung close. No racking is required.

In the last mode the vinous fermentation is completed before barrelling. The spiri-

tuous soon follows, if the temperature remains as high as 60°, and abates in 6 to 12 days.

If the wine becomes foul or ropy, take half an ounce of chalk in powder, half an ounce burnt alum, the white of an egg, and a pint of spring water; beat the whole in a mortar, pour it into the cask, and roll it ten minutes; and as soon as the wine becomes fine, rack it off.

**REMARKS.**—There is too much apathy among our farmers with respect to fruit. Strange as it may seem, it is no less strange than true, that while fruit affords the greatest profit of any branch of common husbandry, besides the pleasure of enjoying in abundance, as every farmer ought to do, it is a thing almost wholly neglected by common farmers as altogether beneath their notice. Even those who do not entirely neglect it, seem to think they do well if they have a few apple trees, which, without pruning, or any other attention, bear poor apples. Probably more than one half of our farmers never saw a handful of gooseberries in their lives. We think if some of them should visit some garden where they are in plenty, and in perfection, and after regaling with them pretty freely, get a treat of good currant wine, we should soon see them cultivating currants and gooseberries.

#### NEW-YORK AMERICAN.

AUGUST 22—23, 1835.

#### EUROPEAN INTELLIGENCE.

**LATER FROM EUROPE.**—By the packet *Geo. Washington*, Capt. Holdredge, from Liverpool, we have our London papers to the 23d ult. inclusive—and annex the most important extracts.

Among these, that which is least expected, is a statement that the successor of Francis of Austria does not mean to follow in the footsteps of his predecessor—as a member of the Holy Alliance—but to withdraw therefrom. The following is a summary thereof:

Private intelligence, received from Vienna, confirms a report previously spread abroad, to the effect that the Emperor Ferdinand was about to secede from the Holy Alliance. Ferdinand has signified his determination neither to be personally present, nor to be represented, at the great review of the northern powers at Kalisch. In vain have couriers been dispatched to him from Berlin and St. Petersburg, with the most pressing invitations; in vain has Russia pleaded the policy of displaying the power of the imperial and royal confederates, in order to overawe the more liberal governments of western Europe; in vain has Prussia rung the gongs of his august father in his ears, and even included Switzerland in the list of the invited States.—The Emperor excuses himself on the plea of a necessity of attending to the internal affairs of Austria; and he refuses to send the complement of troops, alleging that they cannot be spared without endangering the security of the empire. The King of Prussia has done all in his power to obviate these objections, by offering to reduce the thirty thousand troops, first demanded, to six thousand cavalry, and to change the place of consultation from Kalisch to Toplitz, should Ferdinand prefer the latter as the more convenient place for holding the meditated Congress of Sovereigns. But all will not do; and the other great Powers are now sensible that their policy will not find a champion in the Monarch of Austria.

In the House of Commons, on the 21st July, Sir Robert Peel made a very able speech, on a motion made by him, to divide the Irish Church bill. The object of the motion, was to obtain the separate action of the House on the two main features of the bill—that making arrangements respecting tithes, and that contemplating an alienation of the surplus of the Irish Church property to purposes other than ecclesiastical. The Hon. Baronet is said to have surpassed, in this speech, any of his former efforts. The motion was resisted by ministers—the debate had been adjourned to a third day.

In the House of Commons Mr. F. Buxton moved for a Committee of inquiry into the treatment of the aborigines of the British settlements. These were stated by Mr. B. to number five millions! At the Indian Islands and the Cape there were more than one millions of the aborigines. In Australasia, there were from two to three millions, and in New Zealand and other South Sea Islands, not to speak of Van Diemen's land, there were large numbers. These aborigines, from the Hurons of Lower Canada, to the Caffres of the Cape, Mr. B. said, had been treated with desolating severity, by the British occupants: the motion prevailed.

Mr. Ewart obtained a committee "to inquire into the best means of extending a knowledge of the arts, and of the principles of design, among the people, especially among the manufacturing population,—and also to inquire into the Constitution of the Royal Academy, and the effects produced by it." It was admitted on all sides that a knowledge of art was both refining and profitable. Among others,

Dr. Bowring gave his most cordial support to the motion, on the ground that the cultivation of the arts of design had been productive of the most beneficial results in France. In that country art was popular, in England it was aristocratical. In point of fact the French had become *artistical* from habit, and he believed that if this committee were appointed and followed up by practical results, the people of England would soon acquire mechanical aptitude for the fine arts. The works of art were open to all the population of France, and had created in that country what he would call an atmosphere of art. He expected that a similar result would take place in England if schools of design were opened in our large manufacturing towns, as they were in Lyons and other large manufacturing towns of France, for the instruction of the children of our poorer artisans.

The *Morning Chronicle* asserts that the Duke of Cumberland is the person of the "highest rank," alluded to by Mr. Hume in the House of Commons last night, as being, if Mr. Hume's information was correct, liable to impeachment for high crimes and misdemeanors against the State. The Duke is Grand Master of the Orangemen; and the *Chronicle* states that "it was a prevalent rumor in the House that several original 'warrants for lodges' in the various regiments, signed by the Royal Grand Master, have been produced in Committee."

If it shall appear that Orange Clubs really exist to a great extent in the army, it will be an additional reason for disbanding a large portion of it, and remodelling the remainder. It is not consistent with public safety that the Army should continue in its present state. That it is fearfully demoralized, the records of our Police offices prove; but if it is also under a secret party and political organization, there can be no question as to the method of dealing with it which Parliament should adopt.

Until the evidence is published, we shall abstain from making more than one additional remark. If the existence of Military Orange Clubs is proved, Lord Hill, as Commander-in-Chief, must be called to account. If he is cognizant of the formation of such clubs, and has not brought the offenders to trial, his breach of duty will have been extremely gross. If he is not cognizant of them, what are we to think of his vigilance, or of the propriety of continuing him in the command of the Army in these times?

LONDON, July 22.—It appears by the private letters from Amsterdam, that all fears of a renewal of the recent disturbances there had ceased, and that it was generally current that the obnoxious tax, as well as its arrears, will be abandoned by Government. The large standing army kept up in Holland since the insurrection in Belgium has somewhat increased the burthens of the Dutch people, and may be considered as the actual cause of the recent violent proceedings, although from his proximity to the "brave Belges," we do not exactly see how his Majesty the King of Holland could have done otherwise than keep up this force, or leave his frontiers exposed to the predatory incursions of his exceedingly heroic neighbors, who, however they may dislike steel and bullets, have not the slightest antipathy to silver spoons, or, as George Robbins would say, to "jewels and other effects," if the same can be obtained without the aid of "villainous gunpowder."

The Duke Maximilian of Leuchtenburgh, arrived on the 5th at Copenhagen, and was to proceed thence to Stockholm, where his sister the Princess Royal of Sweden and her husband were to meet him.

In France the Peers are still trying the Lyons insurgents—and the French troops at Algiers were harassed, and had suffered serious loss, by the attacks of the Arabs.

M. de Rigny, it is said, will proceed to Naples as French Ambassador.

Prince Leopold of Sicily, left Paris for Switzerland on the 18th. It was rumored in consequence that his proposed match with the Princess Mary of Orleans was put off.

The *Moniteur* publishes a statement of the receipts of the indirect contributions in the first six months of the current year, amounting to 288,983,000 francs, and presenting an increase of 12,134,000 francs, as compared with the first half year of 1834.

The *Moniteur* publishes a royal ordonnance, appointing Marshal Clausel Governor-General of the French African possessions instead of Gen. d'Erion. The same official print announces that Louis Philippe has granted 10,000 francs out of his civil list towards relieving the calamities which the cholera has inflicted upon Toulon. The cases, since the invasion of the disease, amount to 757, and the deaths to 575. At the same date there were 56 cases at Marseilles, of which 11 had proved fatal. The cholera is stated to have broken out also at Montpellier.

LONDON, 23d July.—The Paris papers of Tuesday, received by express, communicate some particulars relative to the defeat sustained by General Trezel at the hands of Abdel Kader, the Arab Chief near Mecta, on the coast of Africa. This serious affair is modified in these journals by the name of a check, although it is admitted that 500 men had fallen, that the fugitives, in their retreat had not time to bring off all their guns and baggage, nor even their wounded; that it was with the utmost difficulty that the infantry were embarked, and that General Trezel with the remains of the cavalry found his way back to Oran. The forces under Abdel Kader are represented as having been well armed, and amounting in number to 15,000; the strength of General Trezel's brigade having been greatly inferior. This misfortune appears to have taken place on the 27th of June, a preliminary engagement having occurred on the 26th, in which the French lost 92 men, including 9 officers, in killed and wounded. It was evidently in the knowledge of this defeat that Marshal Clausel received sudden orders to embark for Algiers, in order to resume the Governorship of the colony.—The foreign legion intended for the service of Her Catholic Majesty appears to have suffered severely in this affair, so that it may be doubted whether what remains of it can be spared until reinforcements are sent out to strengthen the army of occupation.

The affairs of the Queen of Spain look somewhat better. The Queen issued a decree, on the 4th, by which the order of Jesuits is suppressed, and their property ordered to be sold. This is described as being a very wise and popular act. The Jesuits are not favorites with the Spanish populace, though the Mercedian Friars are beloved.

LITERARY PROPERTY IN GERMANY.—The Diet

of the German Confederation adopted, on the 2d of April, last year, the following resolution, conformably to article 18 of the Act of the Confederation: "The Governments have agreed that literary piracy is to be prohibited in all the States of the Confederation, and literary property to be regulated and protected on uniform principles." This resolution is announced by an order of the Ministry of the 19th inst., and it is further stated, that the measures adopted by the respective Governments to enforce their protection "will be made public, after having been notified to the Diet."—[German paper.]

For several years the amateurs in pigeons in Antwerp, have taxed their skill to send a certain number of pigeons to Paris. The first which arrived there gained great rewards for their owners. A similar experiment has been recently made in Paris. One hundred and eighty travelling pigeons were let loose on the morning of June 25th, at the Exchange, at half past 7, for the city of Antwerp, a distance of 90 leagues. One of them, the Great Napoleon, the dean of pigeons, the oldest aerial traveller, was first let loose—he was the bearer of the order of ascension. The other pigeons then took their flight. They had all affixed to one of their wings, the latest telegraphic news in the Exchange—"Zumalcarreguy died June 25." After having soared over the Exchange for about five minutes, they took their course toward the north. A great crowd of people were collected to witness their departure.

#### SUMMARY.

The Dutch frigate *De Maas*, Captain Arriem, of 44 guns, and 340 men, 17 days from Curacao, having on board his R. H. Prince Henry, son of his R. H. the Prince of Orange, and the Dutch brig of war *Sneenid*, Captain Ferguson, of 14 guns, and 74 men, arrived yesterday afternoon at the Quarantine ground. They each fired a salute, which was returned by Fort Hamilton.

The annual Commencement of Yale College was celebrated on Monday last.

Seventy-three youths were graduated with the degree of A.B.

From sixty-five to seventy have entered for the Freshman class of next year, and twelve for the Sophomore.

The honorary degree of Doctor of Medicine, on the recommendation of the Medical Society, was conferred on William Hyde, Nathan Shelton, Lyman Catlin, and Charles Eldridge.

FALL OF A PUBLIC STORE.—The floors of the new public store, at Staten Island, fell in on Friday night with a great crash. The architecture of the center was supported by wooden timbers, standing perpendicularly, and resting at the base upon stone piers, which went down to solid rock. The store has been filling up recently for the first time, and had in it four thousand boxes of sugar, a large quantity of cotton, and various other goods, presumed to contain yellow fever and other pestiferous diseases, to so virulent a degree, that nothing but a large fee to the quarantine officers, could purify them. The goods are now tumbled in one grand *mêlée* into the cellar, where all the seeds of disease must have the very best opportunity to ferment and send forth deadly miasmata. Yet we have no doubt that such is the devotion of the officers there, to the public good, that for a very moderate compensation, they will venture into the center of death's arcana, where they would by no means permit the citizens generally, to hazard their lives.—[*Journal of Com.*]

A singular accident occurred to a steamboat on the Mississippi, on the 12th July. While running close to the shore to avoid the current, a large cotton tree suddenly fell across the boat with a tremendous crash, breaking through the boiler dock to the lower, on which a dozen men were sleeping, all of whom had but time to leap out of danger before the huge trunk sunk deep into the deck, nearly severing one poor fellow in two, crushing the head of another, and slightly wounding one or two others. After the alarm caused by this occurrence had subsided, the tree was cut away and the boat proceeded on her voyage. The tree was ninety feet long and four feet in diameter.

SINGULAR EXPLOSION.—At Boston, on Saturday

the schooner Sarah, lying alongside Central wharf, and loading for Hartford, suddenly blew up, with an explosion that shook the surrounding buildings, and broke all the glass panes in the neighborhood. Happily, no lives were lost. Such, however, was the force of the explosion, that a cask of copper, as we are informed by an eye witness, was thrown on the roof of one of the four story stores on the wharf. The vessel sank immediately.

The extraordinary part of the affair is, that there was no gunpowder on board the vessel—the chief cargo was lime and saltpetre. We are at a loss to account for such an accident under these circumstances. A son of John Tyler, Esq. was injured.

**MR. LAUREAT AND SON'S ASCENSION.—BALLOON.**—The ascension of balloons has become so common in this city, that they have ceased to attract any considerable crowd. Without much public notice, and without it being generally known in the city, Mr. L. A. Laureat made one of the most beautiful ascensions we have ever witnessed. The atmosphere was clear, wind light at S. W. A few minutes before six, P. M., yesterday, the Aeronaut stepped into his car, accompanied by his son, a lad about twelve years of age, and rose gradually, but beautifully, almost perpendicularly, over Castle Garden, where he continued, apparently, for a quarter of an hour and almost stationary, waving his flag; he soon took a current of air which took him gently over the city in an easterly direction, and remained in full view of the citizens for nearly an hour, when the balloon was seen descending over Long Island, in the direction of Newtown. Of all the beautiful spectacles of the kind, we think we have never seen one more pleasing than that we have just described. There were comparatively few persons on the Battery, or in the Garden.

10 o'clock.—Mr. Laureat has returned with his Son: he landed in perfect safety alongside Prince's Garden, at Flushing, twelve miles from this city—and having been one and a half hour in the air.—[Daily Adv.]

The London Literary Gazette, in noticing Fenimore Cooper's last abortion, says that it sent *The Monikins*, with a considerable fee, to one of the monkeys in the Zoological Gardens, in order to have it reviewed in an authentic manner; but the volumes were returned, accompanied by the following laconic note:—"D—d dull nonsense. Yours faithfully, JACOPO!"

**STEAMBOAT SIAM SUNK.**—We are informed by the St. Louis Daily Herald, that the Steamboat Siam, on her passage up the Mississippi from New Orleans, sunk nearly opposite Red river. "The cause of the accident," says the Herald, "was the breaking of her shaft, whereby, in some way, one of her paddles was driven through her bottom, so that she sunk immediately. Most of the cargo was saved, and no lives were lost."

"The Siam was soon raised again, and towed back to New Orleans."—[Cincinnati Whig of 19th Aug.]

**FEMININE AMUSEMENTS.**—The New Orleans papers give notice that a lady has established a shooting gallery on the opposite side of the river for amateurs of both sexes. The hostess proposes to furnish pistols and powder, but gentlemen are expected to bring their own fowling pieces, and ladies their targets! We hope the lady may find "a good run of custom" in this novel and genteel establishment of her's; but it strikes us that she ought to provide accommodations for leap frog, and now and then a boxing match between these male and female "amateurs."—[Cour. & Enq.]

**PRINTING OFFICE DESTROYED BY FIRE.**—The printing office of the "Delaware Gazette and Watchman," at Wilmington, was burnt down on Sunday afternoon last.

NEW ORLEANS, Aug. 10.

The excessive rains we understand have so much injured the cotton crops of West Florida, that the planters have abandoned the Cotton fields; the corn crops are abundant.

**Sugar Crops.**—We regret to state, from good authority that the sugar crop of this State cannot yield more than one half as much as the last season. The prospect in Attakapas it is stated is better than on the coast; some planters on the river

cannot turn out any thing except corn, of which most abundant crops have been made.

**New Flour.**—Flour from new wheat was received in market yesterday by the steamboat Rob Roy, from the Ohio, and found immediate sale at \$7 per barrel.

We are happy to announce the arrival in this city of Col. Stephen F. Austin, of Texas—he came passenger in the brig Wanderer, eleven days from Vera Cruz.

THE TREASURY DEPARTMENT, }  
22d August, 1835. }

This Department acknowledges the receipt of an anonymous letter, without date, enclosing the sum of three hundred and forty dollars, which the writer states is "supposed to be due the United States by error in the settlement of an account."

**ROYAL REWARD.**—By the annexed documents, addressed to this office, and which we translate, it will be seen, that the King of the French, offers one hundred thousand francs, about twenty thousand dollars, as an inducement to seek, and restore to their country, the officers and crew of the French vessel of war *La Lilloise*, employed on a voyage of discovery, on the coasts of Iceland and Greenland.

Our ships, we believe, have little, or no, communication with those shores, and therefore it is not probable, that, through American navigation, the lost will be found, if they ever should be found.—Nevertheless, we give publicity to the documents in question:—

[Translation.]

PARIS, June 18, 1835.

Cabinet of the Minister of the Interior.—Bureau of special attributions.

MR. EDITOR:—Permit me to ask of your indulgence, the publication at an early day, of the annexed Report, addressed by Admiral Duperré, Minister of Marine, to H. M. the King of the French, relative to the Brig *Lilloise*.

You will, I hope, appreciate the importance we attach to giving publicity to this document, and comply with the request here made.

Accept my thanks for so doing, and be pleased, on occasion, to dispose without reserve of my services. I have the honor to be, &c., &c.

CHAS. ~~MINISTRE~~, Chief of Bureau.

To the Editor in chief of the *N. A. American*.

PARIS, June 17, 1835.

[Report to the King.]

SIRE:—The King is apprised that since August 1833, no news of any sort has been received of the *Lilloise*, which under the command of M. de Blossville, lieutenant commanding, (*lieutenant de Vaisseau*) was employed on a mission to the coasts of Iceland and Greenland.

In order to add to the means hitherto adopted to obtain intelligence of this vessel and her crew, your Majesty having expressed the purpose of interesting the mariners of France, and of foreign nations that frequent those regions, I have the honor to propose for your decision—

1st. That a sum of One hundred thousand francs be allowed to any French or foreign mariners, who shall bring back to their country, the whole, or any part, of the officers and crew of the *Lilloise*.

2. That a reward proportioned to the importance of the service rendered, should be granted to those who shall communicate the first certain intelligence concerning them, or procure the restitution to France, of any of the papers, or effects, belonging to the expedition.

I am, with the most profound respect, Sire, your Majesty's very humble, obedient, and faithful servant,

Admiral Peer of France, Minister of Marine and the Colonies.

Approved,

LOUIS PHILIPPE.

By the King,

Duperré,

Admiral, &c. &c.

MISCELLANY.

THE LONDON QUARTERLY REVIEW, No. CVII, for July, 1835.—This number reached us by the Europe, and has occupied some agreeable hours. It is a very good number.

We add some extracts from the capital paper on Gastronomy and Gastronomers.

'APHORISM.—Of all the qualities of a cook, the most indispensable is punctuality.

'I shall support this grave maxim by the details of an observation made in a party of which I was one—*quorum pars magna fui*—and where the pleasure of observing saved me from the extremes of wretchedness.

'I was one day invited to dine with a high public functionary;\* and at the appointed moment, half-past five, every body had arrived, for it was known that he liked punctuality, and sometimes scolded the dilatory. I was struck on my arrival by the air of consternation that reigned in the assembly; they spoke aside, they looked into the court-yard; some faces announced stupefaction: something extraordinary had certainly come to pass. I approached one of the party whom I judged most capable of satisfying my curiosity, and inquired what had happened. "Alas!" replied he, with an accent of the deepest sorrow, "Monseigneur has been sent for to the Council of State; he has just set out, and who knows when he will return!"—"Is that all?" I answered with an air of indifference which was alien from my heart; "that is a matter of a quarter of an hour at most; some information which they require; it is known that there is an official dinner here to-day—they can have no motive for making us fast." I spoke thus, but at the bottom of my soul I was not without inquietude, and I would fain have been somewhere else. The first hour passed pretty well; the guests sat down by those with whom they had interests in common, exhausted the topics of the day, and amused themselves in conjecturing the cause which had carried off our dear Amphitryon to the Tuileries. By the second hour, some symptoms of impatience began to be observable; we looked at one another with distrust; and the first to murmur were three or four of the party, who, not having found room to sit down, were by no means in a convenient position for waiting. At the third hour, the discontent became general, and every body complained, "When will he come back?" said one, "What can he be thinking of?" said another. "It is enough to give one one's death," said a third. By the fourth hour, all the symptoms were aggravated; and I was not listened to when I ventured to say that he whose absence rendered us so miserable was beyond a doubt the most miserable of all. Attention was distracted for a moment by an apparition. One of the party, better acquainted with the house than the others, penetrated to the kitchen; he returned quite overcome; his face announced the end of the world; and he exclaimed in a voice scarcely articulate, and in that muffled tone which expresses at the same time a fear of making a noise and the desire of being heard: "Monseigneur set out without giving orders; and, however long his absence, dinner will not be served till his return." He spoke, and the alarm occasioned by his speech will not be surpassed by the effect of the trumpet on the day of judgment. Amongst all these martyrs, the most wretched was the good D'Aigrefeuille,† who is known to all Paris; his body was all over suffering, and the agony of Laocoon was in his face. Pale, distracted, seeing nothing, he sat crouched upon an easy chair, crossed his little hands upon his large belly, and closed his eyes, not to sleep, but to wait the approach of death. Death, however, came not. Towards ten, a carriage was heard rolling into the court; the whole party sprang spontaneously to their legs.—Hilarity succeeded to sadness; and in five minutes we were at table. But, alas! the hour of appetite was past! All had the air of being surprised at beginning dinner at so late an hour; the jaws had not that isochronous (*isochrone*) movement which announces a regular work; and I know that many guests were seriously inconvenienced by the delay.

The meditation entitled *Gourmandise* is replete with instructive remark; but we must confine our-

\* No doubt Cambacères.

† The friend and principal aid-de-camp of Cambacères.

selves to that part of it which relates to the ladies, who, since Lord Byron's silly prejudices upon the subject were made public, think it prettiest and most becoming to profess a total indifference as to what they eat. Let them hear our professor on this subject—

'Gourmandise is by no means unbecoming in women; it agrees with the delicacy of their organs, and serves to compensate them for some pleasures from which they are obliged to abstain, and for some evils to which nature appears to have condemned them. Nothing is more pleasant than to see a pretty *gourmande* under arms: her napkin is nicely adjusted; one of her hands is rested on the table; the other conveys to her mouth little morsels elegantly carved, or the wing of a partridge which it is necessary to pick; her eyes are sparkling, her lips glossy, her conversation agreeable, all her movements gracious; she is not devoid of that spice of *coquetterie* which women infuse into every thing. With so many advantages she is irresistible; and Cato the Censor himself would yield to the influence.

'The penchant of the fair sex for *gourmandise* has in it somewhat of the nature of instinct, for *gourmandise* is favorable to beauty. A train of exact and rigid observations have demonstrated that a succulent, delicate, and careful regimen repels to a distance, and for a length of time, the external appearances of old age. It gives more brilliancy to the eyes, more freshness to the skin, more support to the muscles; and as it is certain in physiology, that it is the depression of the muscles which causes wrinkles, those formidable enemies of beauty, it is equally true to say that, *ceteris paribus*, those who understand eating are comparatively ten years younger than those who are strangers to this science. The painters and sculptors are deeply penetrated with this truth, for they never represent those who practice abstinence by choice or duty, as misers or anchorites, without giving them the paleness of disease, the leanness of poverty, and the wrinkles of disquietude.

'Again, *gourmandise*, when partaken, has the most marked influence on the happiness of the conjugal state. A wedded pair endowed with this taste have once a day, at least, an agreeable cause of meeting. Music, no doubt, has powerful attractions for those who love it; but it is necessary to set about it—it is an exertion. Moreover, one may have a cold, the music is not at hand, the instruments are out of tune, one has the blue devils, or it is a day of rest. In *gourmandise*, on the contrary, a common want summons the pair to table; the same inclination retains them there; they naturally practise towards one another those little attentions, which show a wish to oblige; and the manner in which their meals are conducted enters materially into the happiness of life. This observation, new enough in France, had not escaped the English novelist Fielding; and he has developed it by painting in his novel of 'Pamela' the different manner in which two married couples finish their day.

'Does *gourmandise* become gluttony, voracity, intemperance? it loses its name, escapes from our jurisdiction, and falls within that of the moralist, who will deal with it by its precepts, or of the physician, who will cure it by his remedies. *Gourmandise*, characterized as in this article, has a name in French alone; it can be designated neither by the Latin *gula*, nor the English *gluttony*, nor the German *husterhelt*; we, therefore, recommend to those who may be tempted to translate this instructive book, to preserve the substantive and simply change the article; it is what all nations have done for *coquetterie*, and every thing relating to it.

Considering the high privileges attached to the character of a *gourmand*, we are not surprised at finding that it is not to be assumed at will. The next Meditation accordingly is headed *N'est pas Gourmand qui veut*, and begins as follows:—

'There are individuals to whom nature has denied a refinement of organs, or a continuity of attention, without which the most succulent dishes pass unobserved. Physiology has already recognized the first of these varieties, by showing us the tongue of these unfortunates, badly provided with nerves for inhaling and appreciating flavors.—These excite in them but an obtuse sentiment; such persons are, with regard to objects of taste, what

the blind are with regard to light. The second is composed of *distracts*, chatter-boxes, persons engaged in business, the ambitious, and others, who seek to occupy themselves with two things at once, and eat only to be filled. Such, for instance, was Napoleon; he was irregular in his meals, and ate fast and ill: but there again was to be traced that absolute will which he carried into every thing he did. The moment appetite was felt, it was necessary that it should be satisfied, and his establishment was so arranged, that in all places and at all hours, chickens, cutlets, and coffee, might be forthcoming at a word.'

The habit of eating fast and carelessly is supposed to have paralyzed Napoleon on two of the most critical occasions of his life—the battles of Borodino and Leipsic, which he might have converted into decisive and influential victories by pushing his advantages as he was wont. On each of these occasions he is known to have been suffering from indigestion. On the third day of Dresden, too, the German novelst Hoffman, who was present in the town, asserts that the emperor would have done much more than he did, but for the effects of a shoulder of mutton stuffed with onions—a dish only to be paralleled by the pork chops which Messrs. Thurtell & Co. regaled on after completing the murder of their friend Mr. Wear.

The gifted beings predestined to *gourmandise* are thus described:—

'They have broad faces, sparkling eyes, small foreheads, short noses, full lips, and round chins.—The females are plump, rather pretty than handsome, with a tendency to *embonpoint*. It is under this exterior that the pleasantest guests are to be found; they accept all that is offered, eat slowly, and taste with reflection. They never hurry away from the places where they have been well treated; and you are sure of them for the evening, because they know all the games and pastimes which form the ordinary accessories of a gastronomic meeting.

'Those, on the contrary, to whom nature has refused an aptitude for the enjoyment of taste, have long faces, long noses, and large eyes: whatever their height, they have always in their *countenance* a character of elongation. They have black and straight hair, and are above all deficient in *embonpoint*; it is they who invented trousers. The women whom nature has afflicted with the same misfortune are angular, get tired at table, and live on tea and scandal.'

Out of the many modes proposed of testing this theory, we shall confine ourselves to one—the judicious employment of *eprouvettes*:—

'We understand, by *eprouvettes*, dishes of acknowledged flavor, of such undoubted excellence, that their bare appearance ought to excite in a human being, properly organized, all the faculties of taste; so that all those in whom, in such cases, we perceive neither the flush of desire nor the radiance of ecstasy, may be justly noted as unworthy of the honors of the sitting and the pleasures attached to it.'

A distinguished gastronome, refining on this invention, proposes *eprouvettes* by negation. When, for example, a dish of high merit is suddenly destroyed by accident, or any other sudden disappointment occurs, you are to note the expression of your guests' faces, and thus form your estimate of their gastric sensibilities. We will illustrate this matter by an anecdote which our author has forgotten to note.

Cardinal Feach, a name of honor in the annals of gastronomy, had invited a large party of clerical magnates to dinner. By a fortunate coincidence, two turbots of singular beauty arrived as presents to his Eminence on the very morning of the feast. To serve both would appear ridiculous, but the Cardinal was, notwithstanding, most anxious to have the credit of both. He imparted his embarrassment to his chef—'Be of good faith, your Eminence:—' was the reply, 'both shall appear: both shall enjoy the reception which is their due.' The dinner was served: one of the turbots relieved the soup. Exclamations unanimous, enthusiastic, religious, gastronomical—it was the moment of the *eprouvette positive*. The *maitre d'hôtel* advances: two attendants raise the monster and carry him off to cut him up; but one of them loses his equilibrium: the attendants and the turbot roll together on the floor. At this sad sight, the assembled Cardinals became pale as death, and a solemn silence reigned in the *concile*—it was the moment of the *eprouvette negative*—but the *maitre d'hôtel* suddenly turns to the attendant—'Bring another turbot,' said he, with the most perfect coolness. The other appear-

ed, and the *eprouvette positive* was gloriously rewarded.

[From "Ship and Shore."]

We did not reach Catania till a late hour of the morning. Here we took thirteen mules—five as substitutes for our own legs—five as sumpters—and three for the accommodation of the guide and muleteers. Thus equipped, with provisions for three days, and with great coats and blankets sufficient to protect us in a region of ice, we started a little before mid-day for the top of Etna. We were determined to see the next sun rise from the summit of that mount.

Our road lay for fifteen miles, among the rugged reefs of lava, disgorged in the last eruption. Every thing around had the appearance of a vast lake, tumbled in a storm, and suddenly changed to solid blackness. The sides of the mountain, as we approached it, presented features of a still bolder fierceness. The huge rock, the toppling crag, the protruding bluff, stood forth in frightful wildness from the channels and chasms which past torrents of fire had left behind. The summit, with its cloud of smoke and shaking cone, crowned the whole with a dark besetting terror.

At sunset, having reached the verge of the woody zone, we alighted for rest and refreshment. We here changed our summer apparel for that of winter; the great coats which had been put on our sumpters by our trusty guide—and which we should wholly have neglected—were now in eager requisition. Thus protected, and with spirits and strength renovated by the repast, we mounted again and renewed the ascent. Daylight had gone, but the sky was clear, and the light of the stars was sufficient for our practised guide. Our mules were sure footed, and we had only to relinquish ourselves to their superior sagacity.

At a little before midnight, while approaching the foot of the great cone, where we were to part with our faithful animals, and where indeed we were to wait for the break of day, things began to wear a fearful change. Frequent clouds swept past us; but there was one at some distance which seemed more stationary—gathering in bulk and blackness. Our guide anxiously watched it, as it collected its strength and threw out its snagged flukes, and quickly leading the way up a steep ledge, called vehemently upon us to follow. We had only gained the ridge when the tempest came. It appeared to me to be the last position one should seek under the tornado which now swept us, for we were obliged instantly to dismount and hold on to the sharp points of the rock. Our mules placed themselves instinctively in a posture presenting the least resistance to the rushing element. It was soon apparent why our guide had taken refuge on this unsheltered steep; for, as the cloud struck the side of the mountain, its enfolded lake descended in deluge and thunder. Rocks and large masses of ice, disengaged by its violence, rolled down on each side of us and over the very track on which we were moving but a few moments before. Though separated from each other but a few feet, yet no one could make himself heard; the torrents around and the thunder above overpowered even the loudly vociferated admonitions of our guide. There was at one moment a darkness that might be felt, and then at another the lightning, flashing down through the rifts of the cloud, would make the slightest pebble visible in its searching light. An hour of these dread alternations, while torrents and rocks were rolling on each side of us—and the storm went past. We were drenched to the skin, while our outer garments began to be stiff with the ice, yet with a shivering accent, we could speak to each other once more. It was the language of one spirit rallying and animating another. Captain Read with characteristic energy, was the first to mount.

Nit actum reputans, si quid superesset agendum.

The reader, without undergoing our fatigue, or being wearied with a detail of incident, will now conceive us about two thousand feet above the point where we had encountered the storm—in a substantial shelter at the foot of the great cone—around a grate of coal, which we had brought with us from Catania—warming our fingers—snapping the ice out of our coats—toasting Etna in a bumper of its own wine—and watching for the break of day. That hour comes: and now let him take his stand with us on the highest point of the cone, ten thousand feet above the level of the sea, and imagine the whole island of Sicily with its peaks and glens, its torrents and valleys, its towns and forests,

It is a strange coincidence that Goethe, in *Wilhelm Meister*, expresses a similar dislike to seeing women eat.

with the broken line of its bold shores stretched beneath in one vast panoramic view—the sun, wheeling up out of the distant sea—the heavens flushed with its splendor—the mountain pinnacles burning in its beam—the great cone abaking with the throes of the unresisting element within—the crater sending up its volumes of steep cloud—and the central lake of fire flashing up through the darkness, like terrific glimpses of the bottomless abyss! But the reality overpowers all description! I drop my pen, and half accuse myself of rashness in having made even this brief attempt.

We effected the descent without any serious injury, though I had myself rather a narrow escape. My mule made a misstep—the only fault of the kind he had committed during the excursion. I fell over his head, and turned many somersets; on looking back, I saw my mule standing on the verge of the slope, and disregarding every thing else, directing his anxious look to me. There was sorrow and self-accusation in that look—I forgave him. Beckoning to him, he came down, snuffed about my mangled hat, and when I remounted, pricked up his ears, and started on with the most assured tread.

The Etna fever, which hurried us blindly past all other objects on our way to the mount, having subsided we determined to defer our return to the ship, and glance at some of the features of Catania. This is a beautiful city, though built upon one vast field of lava, with the dead beneath, a volcano above, and the frightful monuments of the earthquake around. I know not why it is, but some how in this strange world, beauty, danger and death, are always in the same group. The sweetest violet I ever saw, bloomed among wreaths of snow on a sister's grave.

The amphitheatre, where the ancient Catanians held their sports, and where they may have been suddenly engulfed in a flood of fire, stands seventy feet beneath the gay promenade of the present town. This gigantic structure is built itself of lava, and for aught we can tell, may have been reared over play-houses, entombed in some eruption of a still earlier date. Thus it ever is in this world; on land, the votary of pleasure indulges his mirth over the bones of a perished race; and on the ocean, the mariner lightly hymns his song on a wave, through which have sunk thousands to re-appear no more. We present to heaven a picture of life and death, mirth and madness, over which angels might wonder and weep!

Nature often atones for the fierceness of present calamities in the beauty of remote results. The ashes that fall in the burning breath of the volcano nourish plants which are to bloom above those they have buried; and the forest, which now encircles Catania, waves more luxuriantly than the one charred beneath. The vegetable life and bloom which followed the subsiding waters of the great deluge, were not less fresh and fair, than what had been swept away. But man covers the world with his slain—leaving their flesh to the vultures, their bones to the accents of the last trumpet, and his own guilt to the disposal of a final Judge.

We visited, while at Catania, the museum of the prince of Biscari—the largest and most richly stored private cabinet in the world. I pass by the statues of the ancient deities, for time and disaster have been as fatal to their forms as inspiration has to their worship. I pass by the collection of shells, for none in all their vast variety, has the tone and rainbow beauty of the one through which the mermaid breathed my dying dirge. I pass by the vases which held the wines, and the lamps which lighted the festivities of the ancients; for who would gaze on the nail of the coffin, in which youth and affection have sunk from light and life? I pass by the countless minerals and gems—they shed no rays of such living light as those which beam from the eye of the bright gazelle. I pass by the million of embalmed insects,—others swarm the field and forest happy in the life which they have lost. I pass by—no I will not—the expressive statue of Cleopatra. The heart throbs beneath its beauty—the eye swims when lifted to that last look of suicidal despair.

Leaving the museum, we encountered a humble Franciscan in his simple attire—his uncovered head and sandals. He presented us with some flowers, and received in his thin pale hand our little charities. Poor pilgrim! what is this world to thee? Thou hast renounced its wealth, its pleasures, its restless spirit of enterprise: thy home is not here—is it in heaven?—art thou indeed going to that better land, where the strife and vanities of

earth never come? May the privations of thy lot atone for the mistaken virtues of thy creed.

If I determine to become a monk, I will come here and join the Benedictines. They have a splen did monastery, richly endowed—luxuriant gardens—sumptuous fare—nothing to do—they live like gentlemen. If any one questions the usefulness of such a life, I can only say, let him attend to his own business. What concern is it of his, if, like a silk-worm, I wind myself up in my own web? Let him not attempt to wind my house on to his bobbin.

Cicisbeism prevails among the higher classes in Catania. It passes as a pure platonic affection—inflicting no marriage obligation—no law of morality—no rule of rigid propriety—merely a chaste friendship—innocent as a new-born babe. It does, to be sure, encourage a peculiar intimacy, and may perhaps diversify the features of the younger members of the family; but what of that? No sentiment of delicacy has been publicly shocked—and no one dies before his time comes:—let the exquisite arrangement alone. Never was there a charmer of the bird with so beautiful a skin, so bright an eye, and so venomous a fang! It is the devil himself disguised as an angel of light!

Leaving Catania—the excellent hotel of the attentive Abatti—and travelling the remaining half of the day and the succeeding night, we arrived at Messina at the break of day. The leaves were wet with the dew, and the first rays of the sun were among them.

#### Sketch of a Kingston Boarding-house.

From Dr. Madden's twelve months' residence in the West Indies.

I have given one of my friends a little sketch of an hotel in Barbados, the following is a short one of a boarding-house in Kingston:

The stranger, on his arrival, is conducted (perhaps like myself) to a first-rate establishment in East street: his conductor draws up before a large mansion of an imposing exterior, with a multiplicity of windows, on which the late war has evidently conferred no taxes, or at least none affecting the transmission of light or the sea-breeze,—which is so essential to health and comfort that Mr. Pitt should have been ashamed for neglecting to lay a duty on its enjoyment. The stranger is ushered into a wilderness of a saloon, which runs in extent from front to rear, with the exception of a narrow gallery at either extremity, the whole breadth of the building. The saloon is destitute of windows; but there is no dearth of doors on either side and these lead to the bed-rooms. Carpets, window-curtains, and hangings are, very properly, no part of the paraphernalia of the saloon; but, in lieu of these, the stranger slides, at the risk of his neck, over a highly polished floor; and sits down, as he imagines, at the peril of his life, in a state of liquefaction, in a thorough draft, and, for the prevention of cold, calls for a glass of sangaree; and, in the course of half an hour, to obviate the heat—which is fusing his yet "too solid flesh," he is advised to have recourse to the old, simple, unadulterated, "and best beverage after all"—plain water diluted with brandy,—and, before he goes to dinner, to give him an appetite, and dissipate the confounded languor that clogs his energies, he cannot decline a small wine glass full of bitters mixed with Madeira.

He very properly pays his respects, before he dines, to the lady of the house;—on Mohammed's principle of going to the mountain, which will not come to him, he accordingly presents himself before the figure of a stout young gentlewoman, seated in the end gallery, who scarcely moves as he approaches. The stranger is afraid she is an invalid: he asks the way to the dinner-room; the lady points with her chin to the apartment: he fears the poor young woman is a mute; he determines to ascertain the fact:—"I presume, madam, you are the lady of the house?"—The young woman again points her chin in the direction of an old emaciated brown lady, stalking through the court-yard:—"What would your gracious figure" intimate by that? asks the stranger with an inquiring glance. The young woman moves her lips, and, in due time, she deliberately articulates two words:—"My mother."

Why the deuce, thinks the stranger, could she not say so at first, instead of sitting with her hands behind her back, and pointing out her chin, to avoid the trouble of pointing with a finger?

Well, the dinner table is prepared in one of the end galleries, with all the *jalousies* thrown open to admit the breezes; the wine-bottles are dripping

in the window in their cotton bags; the gentlemen are mustering in their white jackets, and the poor ladies plying their cambric handkerchiefs; while the brown waiters, like feathered Mercuries in a galloping decline, are doing violence to the laws of nature in the West Indies; and some invisible agent is accelerating their movements on the stairs, till the dinner is at length served up.

King James says, in one of his treatises, if he were to invite the devil to dinner, he would have three things for his entertainment—"a pig, a poll of ling, and a pipe of tobacco for 'digesture.'" Were it my painful duty to entertain his satanic majesty, I would set before him three dishes, common enough in the West Indies—pigeons, prawns, and pickled salmon; and if these did not astonish his "digesture," I don't know what would.

King-fish and turtle, beef and mutton mystified in various shapes, prawns and roasted pigeons, yams and sweet potatoes, calaloo and garden-egg, and various other delicacies are tried, commended, and despatched; and believe me, sir, an alderman on a voyage of discovery, like the late Sir William Curtis, in his cruise in the Mediterranean, in quest of culinary novelties, might travel a great deal farther than Jamaica and fare infinitely worse, whether in a boarding-house or at a private table.

The attendance, however, is not equal to the fare. Once the stranger loses sight of the waiters, black or brown, he may bid adieu to the light of their greasy countenances, perhaps for hours to come. He may knock at the table till he is tired, shout till he is hoarse—(ring a bell he cannot)—he may call Ned, Frank, Cupid, or Columbus—ay, he may call niggers from the kitchen depths, but, query, will they come? till, at last after apostrophizing them as "waiters!" "boys!" "black fellows!" "you rascals, there!" he winds up with a magical noun substantive of the congregative kind—"Somebody, I say, there!" and, after a decent interval, the die-away tones of the drawing voice of the stout lady below stairs are heard in the interesting inquiry of—"Will nobody come there?" and lo and behold! at last everybody does come, at the rate of a brown hunt, which is about a step and a half in ten seconds.

#### The First Discovery of Columbus.

By the Author of "Specimens of the Early Poetry of France."

[The crew of Columbus, having lost all hope of land, and finding that what he had thought so proved but clouds, began to murmur against this bold Italian, and determined to give him only three days longer to fulfil his promises.—The first of these days he became convinced, by the sunset, that land was near—in the night he espied lights. Two hours after midnight, 11th of Oct., 1492, land was clearly visible. The island on which they landed was Guanahana, which they called St. Salvador.]

"The howling winds forbid us  
To trust the fatal main—  
Oh turn our wand'ring vessel  
To harbor once again!  
Why to this 'bold Italian'  
Our lives, our hopes confide:  
No golden land awaits us  
Beyond the shoreless tide—  
How long shall he deceive us  
With boasting vain and loud?  
And when we gaze for land,  
He can show us but a cloud!"

The gallant leader heard,  
But he listen'd undismay'd,  
Tho' he saw their furious glances,  
And their daggers half display'd,  
No fear was in his soul,  
But his heart was wrung with woe;  
Shall he quail before their murmurs,  
And his glorious meed forgo?  
Had he braved the ocean's terrors  
In darkness and in night;  
And shall he furl his sails  
With the promised goal in sight?  
For he look'd towards the horizon  
And marked the setting sun;  
And, by its ruddy light,  
He knew his toil was done!

'Twas in the deepest midnight,  
As they cut the yielding wave,  
When not a star was shining  
To guide them, or to save,  
As in awful, hopeless, silence,  
Their onward course they steer,  
Far in the murky distance  
Lo!—glimmering lights appear!  
In breathless joy and wonder  
They watch the op'ning sky;  
And, with the morning, rise  
Their rapturous certainty.  
Thro' silvery vapor gleaming  
Extends the welcome strand,  
And trees, and rocks, and mountains,  
Before their view expand.  
They breast the foaming surges  
And shouting leap to shore,  
While every echo answers  
"God! and Saint Salvador!"

[FOR THE NEW-YORK AMERICAN.]

**Musings.—By Flaccus, in the Country.**  
**SERENADE.**"Avec toi tout est jouissance,  
Et rien sans toi!"

The night is still—but not my soul—  
How calm is nature's sleeping breast!—  
Would that, in mine, her quiet stole,  
And I, like her, were thus at rest.

The gentle moon looks mildly down,  
At her sweet gaze the vapours flee;  
But ah!—the clouds that round me frown,  
No beam of love will chase from me—

The night-bird, from his native tree,  
Pours on the air his lulling strain;  
But harshly thrills his melody,  
Amid the discord in my brain.

The winds, a load of sweets divine,  
From out the wood's deep bosom, bear;  
But ah!—the sighs that gush from mine  
Breathe only of the bitter there—

Not song of bird, nor glance of moon,  
Nor breath of woods, my smile inspires—  
Thy voice, thy face, thy sighs, alone,  
Can give the peace my soul requires—

No. 9—

W.

**FOLGER'S FLOATING DRY DOCK.**—We have examined the model of this new and ingenious invention, now exhibiting under the Exchange, and see no reason to doubt that it presents a mode, both cheap and effectual, of repairing—and building too for aught we see—ships, in Dry Dock.

The principle is simply this:—a floating cradle, water tight, and of the dimensions proportioned to the vessels to be docked, is constructed, with a falling gate at one extremity; this being lowered the cradle sinks, so that the vessel may pass into it—when by windlasses the gate is closed—the water within pumped out by a steam engine, and, as it is withdrawn, the vessel is shored up, and supported along the inner sloping walls of the cradle.

Several such docks, of sizes proportioned to merchant ships and vessels of war, would cost little, compared with a permanent Dry Dock, and would have the advantage of being available for use any where—without regard to locality—where they could float. We commend the invention to the notice of the public.

**RUSSIAN COMMERCIAL SPECULATION.**—The foreign journals contain articles attributing great activity to the Russian Government in seeking to open new sources of commerce, and to improve the old. One thing remarkable is, that in most of the projected enterprises a communication with India is contemplated, as is the case in the following speculation extracted from a Hamburg paper received yesterday:—

"It is said, that in the late journey of the Emperor Nicholas to Moscow, the plan for a junction of the Dnieper and the Duna, and for making these two rivers throughout navigable, was taken into consideration, and recognised as a practical undertaking, which, when completed, must have great influence on the half of Europe. While the Danube, being now navigated by steam-vessels, will become a more animated channel of commerce, and the routes of communication with India will be directed more and more to the east—while the intended railroad from Vienna to Galicia appears as a gigantic undertaking, there will be in future numerous ways of intercourse in that direction, and lead Asia to a higher degree of civilization.

"Russia wants nothing but such grand routes to acquire a rapid increase of prosperity and population, as it includes, by its geographical position, all the productions of the north and south. The line of the southern provinces begin to be an important branch of commerce, and will become more so when the intended channels of communication, which will be available at least six months in the year, shall be established. Among them a connexion of the north with the Wolga is spoken of, whether by means of canals or iron railroads is not determined."

Much employment for capital is presenting itself in the United States, and generally speaking it bears a good character with the monied interests of this country. Among the contracts lately entered into is a New York loan, for supplying the city with water, \$200,000. 5 per cent; a Maryland State loan, for canals, 400,000. 6 per cent; and an Alabama State loan, for railroads, 300,000. 5 per cent. The terms of the contract do not appear to be known here at present.—[English paper.]

**PARTNER WANTED.**

Wanted, a partner in an extensive Printing Establishment. No one need apply who is not a thoroughbred printer, competent to superintend and direct an office in which upwards of 30 persons are employed, and able to furnish \$3000 cash capital. The best of references will be given and required. Letters, with real name, may be addressed to P. P. P., Post Office, New-York, postage paid, and they will be promptly attended to. May-4

**TO TUNNEL MINERS, DRILLERS, &c.**

Wanted, immediately, 40 Tunnel Miners, (Cornish Miners will be preferred,) 80 Drillers, 50 Laborers, and two experienced Mine Blacksmiths, on the New York and Harlem Railroad, about five miles from the City. Liberal wages will be given, and cash payments made every fortnight. Apply at Mr. FOWLER'S, St. John's Hall, Frankfort street, New-York.

JOHN RUTTER, Contractor.

The Albany Argus, Philadelphia U. S. Gazette and Pennsylvania, will please copy this, and send their bills to the Railroad Company, 14 Wall street, New-York. 23-4

**NOTICE TO CONTRACTORS.**

Sealed Proposals will be received at the Hudson and Berkshire Railroad Company's Office, in the city of Hudson, until the 5th day of September next, for excavating and embanking 14 miles of their Road from Arnold's shop, near Great's, at Chatham Four Corners, to the state line, and also for constructing 8 Bridges, from 60 to 70 feet each, between the abutments. Plans of the masonry and superstructure of the bridges will be exhibited at the Railroad Office. Contractors will be required to furnish all the materials for bridges; and the masonry to be completed by the 1st of December next. The road to be graded for a double track, 24 feet wide. A part of the road will be heavy rock and gravel excavation. Profiles of this part of the route will be exhibited at the Railroad Office, in Hudson, and also at the Office of the Engineer, at Chatham Four Corners. The road will be divided into sections of one half and one mile each in length, and prepared for examination by the 10th of August.

Proposals will also be received for furnishing 500,000 feet, B. M., of White Oak Rails, 6 by 7 inches square, and 16 feet long. Also, 15,000 Oak or Chestnut Ties, 6 by 7 inches square, 8 feet long, or, if round, not less than 8 inches in diameter, at small end. Also, 500,000 feet of Chestnut, Pine, or Hemlock Sills, 4 by 10 inches, 12, 16, or 20 feet long.

The whole to be subject to the inspection of the Engineer, and to be delivered on the line of the road, by the 15th of April, 1835.

The remaining 18 miles of the route will be put under contract as soon as the line can be prepared.

Persons applying for contracts will be expected, unless personally known to the Engineer, to present with their proposals recommendations as to ability to perform their contracts.

Any information on the subject afforded at the Engineer's Office, Chatham Four Corners.

JAMES MELLE, President.

GEORGE RICH, Chief Engineer.

Hudson, Aug. 1, 1835.

31-3t

**AMES' CELEBRATED SHOVELS, SPADES, &c.**

500 dozens Ames' back-strap and plain Shovels,  
75 do do round-pointed do  
150 do do cast steel Shovels and Spades,  
100 do do Socket Shovels and Spades,  
150 do do steel plated Spades.

Together with Pick Axes, Churn Drills, and Crow Bars, steel pointed, made from Salisbury refined iron. For sale by his Agents,

WITHERELL, AMES &amp; CO.

2 Liberty street, New-York.

BACKUS, AMES &amp; CO.

8 State street, Albany.

34-yf

**RAILROAD IRON WORK,**

Of all kinds, made to order by GODWIN, CLARK & CO., Paterson, New-Jersey.

CAR WHEELS, BOXES, AXLES, and CAR SPRINGS, made and fitted complete, at short notice, and fair prices.

Orders addressed to them at Paterson, N. J., or 24 Broad street, N. Y., will meet with immediate attention.

Paterson, Aug. 19, 1835.

34-ly

**STEPHENSON,**

Builder of a superior style of Passenger Cars for Railroad.

No. 264 Elizabeth street, near Bloecker street, New-York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. J26 tf

**RAILROAD CASTINGS.**

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order car wheels, chairs and knees, and every other description of castings required for railroads. M-ly febl4

**RAILROAD AND CANAL MAP,**

Or a Map of the United States, 24 by 40 inches, on which is delineated all the Railroads and Canals in use, or in course of construction, and most of those in contemplation; together with a concise description of, or reference to, each, and containing over 70 pages of letter press. The map is on bank note paper, and put up in pocket form, with morocco cover, or in paper cover, and may be sent by mail to any part of the country Price \$2.

D. K. MINOR,

25 Wall street, New-York.

**RAILROAD CAR WHEELS AND BOXES, AND OTHER RAILROAD CASTINGS.**

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS.

Also, Flange Tires turned complete.

J8 ROGERS, KETCHUM &amp; GROSVENOR

**PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.**

Railroad Spikes of every description required, made at the Albany Spike Factory.

Spikes made at the above Factory are recommended to the public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to admit water.

Orders may be addressed to Messrs. FRANKLIN CORNING & CO., Albany, or to THOMAS TURNER, at the Factory, Troy, N. Y. sept.12-ly

**RAILWAY IRON.**

95 tons of 1 inch by 1/2 inc. Flat Bars in lengths of 290 do. 1 1/2 do. 14 to 16 feet, counter sunk 40 do. 1 1/2 do. holes, ends cut at an angle 800 do. 2 do. of 45 degrees, with splicing plates and nails to suit 800 do. 2 1/2 do. soon expected.

250 do. of Edge Rails of 36 lbs. per yard, with the requisite chairs, keys and pins.

Wrought Iron Rims of 30, 33, and 36 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels.

Axles of 2 1/2, 3, 3 1/2, 3 3/4, 4, and 4 1/2 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and incorporated Governments, and the Drawback taken in part payment.

A. &amp; G. RALSTON.

9 South Front street, Philadelphia. Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them. d7meowr

**SURVEYORS' INSTRUMENTS.**

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by

E. &amp; G. W. BLUNT, 154 Water street,

J21 6t

corner of Maiden lane.

**SURVEYING AND ENGINEERING INSTRUMENTS.**

The subscriber manufactures all kinds of Instruments in his profession, warranted equal, if not superior, in principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Goniometer, with two Telescopes—and a Leveling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes.

WM. J. YOUNG.

Mathematical Instrument Maker,

No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested.

Baltimore, 1833.

In reply to thy inquiries respecting the instruments manufactured by thee, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish thee the following information. The whole number of Levels now in possession of the department of construction of thy make is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accident to which all instruments of the kind are liable.

I have found that thy patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a revolving telescope, in place of the vane sights, leaves the engineer scarcely any thing to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,

JAMES P. STABLER, Sup't of Construction

of Baltimore and Ohio Railroad.

Philadelphia, February, 1833.

Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Germantown, February, 1832.

For a year past I have used Instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these Instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

HENRY R. CAMPBELL, Eng. Philad.

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, SEPTEMBER 5, 1835.

**NEW-YORK AND ERIE RAILROAD.**—We are gratified to learn that about 40 miles of this road along the valley of the Delaware is nearly ready to be put under contract, and that the work will be commenced this season. In addition to this, some thirty-five miles more, on this side of the Shawangunk mountain, will also be ready to be put under contract this fall; and that the work will be prosecuted with great vigor on the opening of the ensuing spring. This is as it should be; and we trust that the work will be looked upon by the next Legislature with less of jealousy than by the last.

It will be recollected by those who read the report made by Judge Wright to the Legislature, and published in this Journal, that Mr. Seymour, the Assistant Engineer, who had charge of the surveys on the eastern division, suggested the propriety of tunnelling this mountain—by which about one hundred feet elevation would be avoided. This suggestion was favorably received by the Company, but in order that a measure of such magnitude might be duly considered before it was undertaken, it was deemed advisable to take counsel from some of the ablest and most experienced Engineers in the country; and in accordance with this decision, JONATHAN KNIGHT, Esq., Chief Engineer of the Baltimore and Ohio Railroad, and MORDECAI ROBINSON, Esq., formerly of Virginia, but now, we believe, of Pennsyl-

vania, were invited by the Company to examine this route. In compliance with this invitation, those gentlemen have passed over the ground in company with Judge Wright, Mr. Seymour, and some of the Directors, and have advised the tunnelling of the mountain, as suggested in the report of the Engineer, to the extent of about half a mile, and at a cost of about \$150,000. By this measure the elevation will be overcome by locomotive power alone, and the inconvenience of stationary power avoided at that point altogether.

Messrs. Knight and Robinson have also, we understand, expressed much confidence in the feasibility of the entire route of the road, and have concurred with Judge Wright in recommending a plan of the whole work, which will reduce its cost below the original estimate made by the Directors—which opinions will serve to confirm those who were before confident, and convince those who doubted, of the practicability and entire success of this important work.

We shall endeavor to give the very able report of these gentlemen in our next.

**ENLARGEMENT OF THE ERIE CANAL.**—We find, in a late number of the *Utica Observer*, an able communication upon the subject of the enlargement of the Erie Canal. It treats the subject coolly and dispassionately, yet in a manner which shows the writer to be master of the subject on which he writes, and that he duly appreciates the importance, now that we can do so, of correcting those errors which, for want of experience in its construction, were almost unavoidable.

It is highly important, in a second effort, that the plan adopted should be fully equal to the prospective demand. What does it matter, now that it has been tested, and found capable of sustaining itself upon almost any scale of magnificence which may be adopted, in its enlargement, if it cost ten, or even fifteen millions, if the business of the country will warrant it? At this day, the question should not be *what will it cost,*

but rather *what will the business require within the next fifty years!* Answer this question, and then make the work for the least money possible. It is therefore highly important that the people at large should be heard upon the subject—and we would recommend that meetings be held for that purpose, especially in this city; for no part of the country is more deeply interested in the measure than the city of New-York.

**AUBURN AND SYRACUSE RAILROAD.**—The Auburn Journal of 26th August says, "by a notice to contractors, in our advertising columns, it will be seen that the contracts upon this road are soon to be made. The route, for a good part of the distance, is already decided upon, and the intermediate space will be settled in the course of a week or two."

The completion of this road will surely be of immense importance to that flourishing village. The citizens of Auburn will secure to themselves, by their enterprise and energy, the immense travel which they would have lost, if the Railroad were to be made along the line of the Canal. Let them complete this road in a substantial manner, and they cannot be deprived of the travel.

While upon this subject, we would call attention to the description of that beautiful and flourishing village, which will be found in this number of the Journal. To the correctness of most of it, we bear testimony from long acquaintance, and doubt not of its becoming one of the most extensive manufacturing towns in the interior of the State.

It affords us pleasure to be able to lay before our readers information from authentic sources in relation to those flourishing inland towns which are rapidly growing to be cities.

The river is in excellent condition, and the canal is in the "full tide of successful experiment." Four steamboats were busily engaged, this morning, in taking in cargo.

The weather is remarkably cool, the effect, no doubt, of heavy rains to the north, so that we confidently anticipate an additional and considerable rise of the river by Wednesday.—[Pittsburg Gaz., Aug. 31.]

[For the American Railroad Journal.]

*Auburn—its present growth; its future prospects; its railroad; its manufacturing power, &c.*

Public attention is awakened to the advantages and value of property at Auburn. Real estate is cheaper there than it is in any other growing village in our State. There has not been a period from its foundation in 1805 to the present time, when it has a population of 6 or 7000 inhabitants, that it has not been in a healthy progressive state from its own inherent energy; and whoever looks upon it now will discover no appearance of decay, but in its beautiful dwellings, scattered in every direction, and in its long ranges of three and four story stores of hewn stone, its magnificent hotels, its numerous and splendid churches, and other public edifices, completed and in the progress of erection, will see much to gratify his taste and assure him that he is in a thriving village. When he reflects that this place was once upon the great turnpike thoroughfare, but by the construction of the canal, which passes it at a distance of 8 miles, it was thrown in the back ground, he will naturally look around him for the causes of its constant growth and present apparent prosperity. A little observation and familiarity with the surrounding country will satisfy him. He will discover that it is a central point in one of the most fertile regions of the globe, and that it must always command the trade of the country lying between the Cayuga and Skaneateles lakes; that it is in the neighborhood of the quarries of plaster, (or gypsum,) which supply the farmers with that article in Pennsylvania and New-York, and near to the supplies and manufactories of salt at Montezuma and Salina; and that it has within a few miles of it navigation by the canal, by the Cayuga and Seneca lakes, by the Seneca river and the great lakes, Ontario, &c., to all parts of our continent. This country, abounding in wealth, from its agricultural productions and its mines, and the means of transportation, must have a vast amount of internal commerce. Its only disadvantage, which is its want of means of transportation to the great channels of internal commerce, is soon to be removed by the construction of the *Auburn and Syracuse Railroad*.

A railroad company is formed under an act of the Legislature with power to transport persons and merchandize from Auburn to Syracuse. The stock has been wholly taken by the citizens of the two villages and the intermediate and surrounding country. The surveys are now completed, except that a part of the line is to be re-examined. The company intend to complete the work in the course of the next season. The engineers estimate the whole cost of the road, which is to be made in the most substantial manner, at \$300,000. The capital of the company is \$400,000. The distance is about 26 miles.

This road, in addition to being a part of the line of the great thoroughfare, will

have the advantage, not only of carrying goods and produce, as part of the great western trade, but also, of the local transportation from Auburn and its vicinity, and intermediate country, to the canal at Syracuse. The amount of this business is almost incalculable. It embraces the merchandize and country produce which is bought and sold at Auburn; the produce of the inexhaustible stone quarries and lime at Auburn; the raw materials and manufactures at the State Prison, which employ constantly 700 hands; the trade through Owasco lake from Homer and its surrounding country; the trade from Skaneateles, Camillus, Marcellus, &c., and also the great manufacturing power of the village. To these sources of revenue, which must make it one of the most profitable railroads in the State, may be added the great travel which the business between the two places must necessarily create.

**Manufacturing Power.**—The water power at Auburn is immense. The small amount of it which has yet been improved does not, perhaps, so much exhibit a want of enterprise among its citizens as it does the remarkable fact, that it has so long escaped the prying scrutiny of speculation. It may, perhaps, be accounted for by the fact, that enterprise has, for a few years past, followed closely the line of public improvement, and neglected many advantages not directly in its course. Within a mile from the centre of the village, upwards of 130 feet of perpendicular fall can be created in the Owasco creek: a never failing stream, which issues from a lake, two miles from the village, forming a basin 12 miles long, with an average of one and a half mile wide. The stream is subject to no floods: the water gradually rising and falling in the lake about five feet in the course of a year. The bottom of the creek is limestone rock, and the banks convenient for damming and erecting works. An incorporated company is about constructing a canal for navigation, as well as hydraulic purposes, from the lake to the village, which will afford them a head of forty feet water, and enable them to discharge the water from their works into the pond of another owner in the centre of the village. The amount of flouring mills, manufactories, machinery and mechanics, which the water power at this village may put in operation, is incalculable. There can be no doubt, that from its position in the centre of a fertile and populous country, where provisions are abundant, the excellence of building materials, the perennial supply of water, its equable discharge, its great reservoir, its immense fall, its access to market, that Auburn is one of the best, if not the very best, manufacturing stations in our State. It is destined, beyond all question, to become within a very few years, from the number and magnificence of its public and private structures, and the beauty of the surrounding country, one of the largest and most desirable and popular of our interior cities.

[From the Utica Observer.]

*An Appeal to the Citizens of Oneida county, on the Enlargement of the Erie Canal*

The importance of the project which was authorized by the last Legislature, to wit., the enlargement of the Erie Canal, demands the most serious attention of the citizens of Oneida. Their interests it is apparent is common with many other counties of the state, indeed all that have an interest in the navigation of the Canal must be concerned in this measure, which is designed to extend its capacity, the economy of its navigation and its general usefulness. But we appeal especially to the citizens of our own county, with whom we feel a common interest in its character for its intelligence and enterprise, and also for its prosperity. To you, fellow citizens, we look for an attentive examination of a project which deeply affects your interest.

Had any man predicted at the time the Erie Canal had its original dimensions settled, that in less than 10 years after its completion the Legislature would have authorized the doubling of its locks, and the enlargement of its dimensions, and that this would be done because the Canal had already about reached its capacity with single locks, he would no doubt have been considered a visionary, whose opinion was entitled to no more weight than a dream. But, chimerical as it would have appeared, experience has unfolded its reality; yes, in less than 8 years the Canal Commissioners recommend the construction of a second set of locks, and in less than 9 the Governor recommends the enlargement of the Canal, as a necessary measure in connection with the doubling of the locks.

In his last annual message to the Legislature, the Governor, in relation to doubling the locks, says, "I regret that the measure was not accompanied with another almost equally necessary, providing for the enlargement of the capacity of the Canal: for I deem it important that the new locks should be made with reference to this latter improvement." The Canal Commissioners on the subject, (see their report of January 1835, Assembly Documents 143,) remark,— "But on the eastern section of the Erie Canal, the crowd is already considerable and rapidly increasing." \* \* \* \* "It is the common navigable strait between the Atlantic and the great western lakes, and by position designed to accommodate the trade and travel of the enterprising and rapidly increasing population of the territories bordering on those lakes and their tributaries, almost illimitable in extent and inexhaustible in fertility. The necessity, now felt, of affording increased capacity to the Canal east of Syracuse, will in a few years be felt in its whole extent: the precise period may be disputed, but the event is certain." Page 20 of same report, the Commissioners say, "If, in the spirit of an enlightened and liberal policy, adequate capacity shall be afforded to the Canal, our western brethren will be accommodated, and their comforts increased; the resources of the state be augmented; a rich and increasing commerce will excite and reward the industry, enterprise, and skill of our citizens, in agriculture, arts, and commerce; and the state, by affording the utmost facility to that busy intercourse of trade, which improves the moral and social relations of civilized life, will at once confer on its own citizens the most lasting benefits, and on all others, in the only measure in which a bountiful Providence permits states to do them good—the greatest benefits and

blessings. "The Commissioners, therefore, respectfully submit to the Legislature that provision be now made by law for all improvements in the Canal which the Legislature shall deem necessary. The extent of these once settled, every step in the progress will be uniform, consistent, and tend to the desired result. The limits of the canal once prescribed beyond the reach of probable change, our own citizens will be the better enabled to make their contiguous and substantial improvements and direct their energies, to the increase of their wealth and happiness. The citizens of other states, in these improvements, once authorised, will find a perfect guarantee, that the products of their industry, through this Canal, will always find a free and easy transit to and from the Atlantic and the Lakes,—and trade and transportation will be invited to it, by the strong inducements of interest."

The Canal Committee of the Assembly, to whom this subject was referred, made a special report, (see Assembly Documents 354,) which, together with the document above quoted from, should be carefully read by every citizen who thinks himself worthy to reflect on the interests of the public. The committee remark—"The history of the past fully confirms the opinion entertained by those who have had the opportunity of observing the progress of our internal trade, that the time is not very far distant when the business on the Erie Canal will require the constant use of double locks, with all the advantages of an enlarged Canal and the consequent increase in the tonnage of boats."

"Within the last eight years the business on the Canal has nearly doubled, although but a small portion of that business has been derived from places beyond our own limits. Still our resources are but partially developed, and without regarding the trade from other quarters, it is not too much to anticipate that the Canal in its present condition will soon be inadequate to the wants of our own citizens. It is estimated that one seventeenth part only of the trade on the Erie Canal, is from parts without the limits of our own state; and yet the business during the last season was nearly or quite equal to the capacity of the Canal for its accommodation. It is already estimated that the detentions of a boat making a trip from Albany to Buffalo and back, during the most active season of navigation, are equal to the loss of two days; and this difficulty must increase with the increase of internal trade."

"Although but a small part of the revenue of the Erie Canal has thus far been derived from abroad; the progress of settlement and cultivation in the great and fertile regions of the west, which must naturally seek a market through the state of New-York, affords the most satisfactory assurance that the tonnage on the Canal will very soon be doubled, without taking into account the increase of our own trade."

In the reports referred to, there is much interesting matter in relation to the importance of securing to the state the trade of the extensive territory beyond its borders, which from its physical geography will most naturally seek New-York as the avenue of communication to the Atlantic. This trade is highly important to the state in general, in regard to the revenue it will produce. The city of New-York has a deep interest in its full development, and it will greatly augment business in the vicinity of this great thoroughfare. But to us, in Oneida, the great object is to have an easy and cheap communication to the Atlantic

market. The influence of the question of enlargement on the economy of transportation, is highly interesting to all concerned in the navigation of the Canal, and particularly to the agricultural interest. It is obvious that our agricultural productions constitute a large item in the tonnage of the Canal, and when taken in connection with the heavy articles of merchandize, salt, lime, and gypsum, consumed by the agricultural portion of our community, the interest of the farmers of our county, in obtaining cheap transportation, will appear far greater than that of other citizens: and demands from them a corresponding attention to the great enterprise under consideration.

In relation to the economy of transportation, the Canal Commissioners in their report before referred to, observe: "The increased width and depth of water would afford a canal of easier traction, and in the navigation of which, boats would be less exposed to injury than they are at present from contact with each other, or the banks. A moderate increase in the length would add much to the tonnage of the boat, and if the cross sections were the same, would require but a small addition to the power of traction. In truth if the Canal and boats were enlarged in this manner, to double the tonnage now usual, the crews to manage and the teams to move the boats would be about the same as now employed on the Canal."

On this point the Canal Committee in their report (before quoted from) says: "By doubling the locks, and increasing the capacity of the Canal, so that it will admit boats of 120 tons burthen, will reduce the charges for transportation more than 50 per cent. exclusive of tolls, which will be a reduction of over 25 per cent in the aggregate expense; and the Canal will be in a condition to accommodate more than four times the present amount of business." A reduction of 25 per cent. on the freight now constituting the regular tonnage, is itself of great importance. Last year it was estimated that more than \$3,000,000 was paid for transportation; twenty-five per cent. would be a saving of \$750,000—or more than half the tolls—and when the business reaches four times the amount of last year, this item will be three millions per annum. When this period arrives, we could afford to pay half the present tolls and have a navigation cheaper than the present Canal would be free of toll. But there is another, and to our county perhaps more important, advantage in this reduction of expense: in the facility it will afford of sending to market articles that will hardly bear transportation at present rates. The soil and climate of Oneida county in general is better adapted to produce the coarse grains than wheat. At times, the Atlantic market will enable us to pay transportation on these products, but the price is not always sufficient. If the reduction contemplated may be realized, then our corn, oats, and barley would become articles of cash value at fair rates. We could rely upon a fair cash price for our corn, with as much certainty as the farmer in Monroe does for his wheat. The importance of the contemplated reduction is too apparent to need further demonstration, to an intelligent community; and we only call attention to the leading points on this subject, believing our fellow-citizens will not be slow to see their importance, or to pursue such measures as will secure the object.

From the quotations before made, it will have been seen that, whether we regard the capacity that will be required, or the

economy of its navigation, the enlargement of the Erie Canal is highly important. The opinions given are not those of men enamored with a darling project that has flattered to recommend it but their enthusiasm, but they are the result of indubitable facts: facts that are open to the investigation of all that feel an interest in the subject. The facts have indeed compelled the adoption of opinions more rapidly than most men were willing to yield assent to the evidence of their senses, the mind being reluctant to keep pace with the rapidly accumulating demands of business. The subject has not received the attention its great importance demands from an intelligent community. This is obvious from the fact that, in all the recommendations, no definite dimensions are proposed, and it is known that the Legislature authorised nothing specific, but gave the Canal Board authority to settle such dimensions as they should deem proper. The Canal Committee proposed that the enlargement should be sufficient for boats of 120 tons, but the dimensions most suitable for this they left to be decided by the Canal Board.

The Canal Board have had a meeting and decided to enlarge the Canal to 6 feet deep and 60 feet wide: but have also authorised an estimate of the cost of 6 feet deep and 60 feet wide, and of 7 feet deep and 70 feet wide, to be submitted to them at a meeting to be held the 20th of October next. The authority for the estimate may be considered a tacit expression of the Board, that they will re-consider this matter at their October meeting. The dimensions, as settled, are believed to be entirely incompatible with the prospective demands of the business, and it is therefore proposed to examine the question.

The Canal was originally constructed 4 feet deep, and the water has subsequently been raised from 3 to 9 inches generally. The boats draw usually 2½ feet, and rarely exceed 32 inches, and carry an average burthen of about 35 tons. To raise the water from 15 to 21 inches is, therefore, all that will be practically obtained in additional depth over the present water. It may be asked, why do not the boats draw a greater depth? The reason is, the sand and mud that is deposited in many places on the bottom of the Canal, forms bars that are liable to ground boats of greater draft, and the delay to which boats of deeper draft are subject to, prevents their general adoption. As a further reason, it is generally believed that boats do not manage as easily when drawing near the bottom. The Board propose to lengthen the chamber of the locks 15 feet, which will increase the capacity of the boat. It must be kept in mind, that a small boat may navigate a Canal of less comparative dimensions than a larger one. A small boat may be controlled and its direction more readily changed in the danger of contact with other boats, or objects against which it is liable to run, than a larger one; consequently the large boat requires more liberal proportions in the Canal it navigates.

The present Canal is adapted (as appears by a table in the report of the Canal Commissioners) to boats of about 30 tons burthen, to afford the most favorable traction at a moderate velocity, and a Canal of about 6 feet deep, 60 feet wide, and locks of 105 feet chamber, (as directed by the Canal Board,) would by the same calculation be suitable for boats of about 70 tons burthen. But the Erie Canal boats are estimated to average about 35 tons, and in some instances boats have carried 50 tons. Judging from the usual practice on the present Ca-

connected with the fact that a large boat will require more proportioned dimensions in the Canal, we are not warranted in calculating the enlarged Canal as adapted to boats of more than 70 tons burthen, or double the present capacity; and when the locks are doubled equal 4 times the present capacity with single locks. Is this calculation at all commensurate with the prospective magnitude of the trade to be accommodated? The Canal Committee in their report recommend such a Canal as will accommodate boats of 120 tons burthen; and by a table given in their report, as also in the report of the Canal Commissioners, it appears that a Canal adapted to the most favorable navigation of boats of 130 tons burthen, requires 8 feet depth of water and 80 feet width at surface. But the dimensions settled by the Canal Board will only be sufficient for about half this burthen. Now, it is not pretended, such a Canal will not float a larger boat, nor that a larger one could not be navigated: but it is settled by the rule of calculation referred to, that such a size is necessary, for the most economical and convenient navigation. This is also corroborated by experience on the Erie Canal, when the average load exceeds the rule of calculation only about one sixth; and it is apparent the rule should not be exceeded when applied to larger boats, if safety, convenience, and economy in the navigation, is to be secured.

In adopting a liberal plan for the boats in general use, we shall have the advantage of a navigation, that in seasons of great pressure in business, an additional 20 or 30 tons may be taken in the boat that usually carries 120 tons, a consideration of great importance.

The Canal Commissioners consider it important, as will be seen in the quotation from their report, that such dimensions should be settled as will meet the prospective demands of the trade, and thereby avoid the necessity of further enlargement: which is no doubt the correct view of the subject. The inhabitants of towns, villages, and cities on the Canal, will desire to make permanent improvements on its banks; which will render further enlargement expensive, and a severe encroachment on the established business arrangements of the country; it will be less expensive to make all necessary enlargements at one, than at two different times; and the work may be better done.

When the Canal was commenced, its success and ultimate productiveness, was, in the view of a large portion of the citizens of the state, highly problematical; and many believed it would load the state with debt, only to be relieved by heavy taxation. But the problem has been solved by experience, which now exhibits the most conclusive demonstration, and will leave us wholly without excuse, if we fail to meet the question, on the scale demanded, by the clearest evidence of its prospective magnitude and importance.

The Canal Commissioners, in their report, say, "that doubling the locks will not double the capacity of the Canal." This is obvious, as no lock can be placed so conveniently for the navigation as the one that lays directly on the towing-path. Boats will enter and leave this more conveniently, and with less delay than they can the 2d lock. A 3d lock should never be thought of, as the delay in passing a 3d set on the eastern section would greatly embarrass the navigation, if only one towing-path was used. The passing each other on one path, of such a number of boats as would require 3 set of locks, would produce delay and ma-

terially enhance the expense of navigation. Very little reflection is required to show, that the most economical navigation would be that which required only one set of locks, which is a further consideration for a canal of liberal dimensions, that the navigation may not be subjected to the delay incident to the necessary use of the 2d set of locks, when it is practicable to avoid it. To remedy this by a towing-path on the berme side, is considered by the Canal Commissioners, in their report, as incompatible with the accommodation of business on its borders, as also the convenient navigation of the Canal itself: We are, therefore, brought to a single towing-path and a double set of locks, as affording the maximum capacity of the canal.

From the suggestion of the Canal Commissioners and our own observation, we infer that the 2d set of locks would do about two-thirds the business of the 1st set: and if the capacity of the boat is doubled, we may estimate the entire capacity of the Canal when enlarged to 6 feet deep and 60 feet wide, in comparison with the present capacity as 10 to 3, or a fraction over 3 times.

By the report of the Canal Committee, it appears the business on the Canal has, excepting a small fraction, been confined to our own state. In view of the increased facilities that will be afforded by the enlarged Canal, in cheapening transportation, the improvements that may confidently be expected in our agriculture, the extension of our mechanic and manufacturing operations, and the tributaries that will be created by new lateral Canals, can we entertain any reasonable doubt, the business of our own state will alone double in the course of the next twelve or fifteen years? Since the completion of the Canal it has doubled in about eight years. If then the Canal is made 6 feet and 60, at the end of fifteen years we shall have it fully occupied for single locks, by the business of our own state; and the only resort to provide for further increase of our own business would be in doubling the locks; and if no other trade was to be provided for, this subject might be considered a reasonable provision. But when we look beyond the limits of our own state, and traverse the extensive and fertile regions that will naturally seek this channel as the avenue of intercourse with the Atlantic market—a district just emerging from a wilderness, and filling up with an intelligent and enterprising population,—can we doubt for a moment, that the capacity of the canal should be at least as large as will accommodate boats of the capacity recommended by the Canal Committee, to wit: 120 tons burthen. It is not necessary to enter on any contested ground, for there will be as much as we can accommodate by a Canal on the most liberal scale, that will seek this route in preference to any other, if we provide the means for its accommodation. But if our means are inadequate, still a large share will press into the Canal, and we must feel the delays and embarrassments it will unavoidably produce, in the enhanced price of transportation.

If this project was one that might load the state with a heavy debt, that could only be paid by imposing a general tax on its citizens, then, however bright might be the prospects of its ultimate utility, to those immediately interested in its navigation, there would be reason to proceed with greater circumspection in the degree to which the improvement should be carried. But on this point there is no further ground to doubt. On the contrary, there is the most ample reason to conclude that the surplus

revenue will in a few years, (at most 4 or 5,) pay the difference between the cost of 6 and 8 feet depth. It is believed by men familiar with this work, that the difference between 6 and 8 feet depth and corresponding width will not be more than \$4,000,000. But to provide most liberally, suppose it cost \$5,000,000 more; it will not require the revenue on the present tolls, over and above its maintenance, more than 4 or 5 years, and then we shall have a navigation that may be considered good for the next 50 years. Is it wise to do less?

We do not censure the Canal Board; they have been compelled to make their decision without any expression of the wishes of their fellow-citizens on the subject; for until their decision was published, we were slumbering over this important matter. We have been informed that one of the considerations that influenced the Board was, that no public meeting of citizens or their memorial indicated the importance in which they viewed the project of enlargement. But, as before observed, the Board have left this subject with a tacit expression, that they hold it open for re-consideration in October next. Let us then lose no time in obtaining such an expression of opinion, by public meetings and memorials, as will leave the Board no ground to doubt, that to comply with the wishes of their fellow-citizens, as well as to meet the magnitude of the object, a Canal of 8 feet in depth, and from 70 to 80 feet in general width, is indispensable.

While surrounded by pressing calls of business, we have briefly called your attention to some of the considerations involved in this project, and we hope, fellow-citizens, you will take such measures as will secure your own interest, and promote the honor and prosperity of the state.

Shall a work of eminent usefulness, deeply affecting the interest of the state, fail to receive that degree of perfection which is demanded by the clearest demonstrations of its importance? It is not for the benefit, or to please the ambition of an individual, who may control the destinies of millions, to gratify a love of splendid things; but, on the simple principle of usefulness, in affording the means of easy communication to market for a numerous people, it is a magnificent project, and peculiarly demands the attention of a government that is formed for purposes of utility. The means of accomplishment are fully provided in the work itself; not the least prospect of embarrassing the state with tax to defray the cost, can be indulged. It is indeed the grand artery, through which circulates the elements of our prosperity. Shall it then be said, the people of the State of New-York have not the sagacity to appreciate the importance, or the enterprise to promote a work so deeply affecting their interest, and which at the same time is of so easy an accomplishment? They have only to say the word, and the work is done. And what will be done? Let every citizen who regards the interests or the honors of the state, read carefully the reports that have been referred to, and reflect on the importance of the project, and we feel assured that an efficient effort will be put forth to accomplish the work on a scale that will be commensurate with its importance, and, in point of utility, will render it an imperishable monument of the wisdom and enterprise of a free people.

[From the Newark Dat. Adv.]

NEW-JERSEY RAILROAD.—We have received from an authentic source the following statement of the number of passengers carried on the Railroad between Newark and New York, since its opening for use, which, it will be recollected, was in the

middle of September last. The immense number of passengers which have passed over the Road, and particularly the great and constant increase, notwithstanding the large patronage which the Steamboats and Stages are receiving, demonstrates we think, conclusively, that in a year or two, the intercourse between our town, and the city of New York, will be almost like a continuous ferry communication.

The facilities now afforded our citizens for carrying on their business with the Emporium, furnishes a substantial cause for the present great and pervading prosperity of Newark, and (whatever may be the mania in other places,) justifies the steady advance of real estate in all parts of the town.

*Statement of the number of passengers carried on the New Jersey Railroad between Newark and New York, from Sept. 15, 1834, to August 1, 1835.*

From September 15, 1834, to March 1, 1835, 51-2 months, there were carried an average number of	7,594 passengers per month, or	41,712
From March 1, 1835, to April 1, 1835,		8,516
From April 1, " to May 1, "		10,036
From May 1, " to June 1, "		12,540
From June 1, " to July 1, "		13,923
From July 1, " to August 1, "		16,923

Total	109,940
If the number for August be the same as July,	16,223
And half that number to the 15th Sept.	8,111

**The total number carried in a year will be 196,483**

The Cincinnati Gazette of the 23d instant, says, that the Ohio River, at this time, is becoming quite low; affording sufficient water only for light draught steamboats to Wheeling. We are informed that the average depth of water in the channel above, is not more than twenty-six inches.

There is only three feet water in the Louisville Canal.

The Pittsburgh Gazette of the 28th inst., says, that the river is in good navigable condition, and from the present appearance of the weather, we judge that we will have more rain, and an additional rise of water.

The Cincinnati Gazette of 23d August says, that in consequence of repairs to the aqueduct, on the lower level of the Miami Canal, about ten miles from the city, the Canal has been only in partial operation for the last two weeks. It will be nearly the same length of time before it is fully repaired, so that boats can travel the entire route.

In addition to the daily line of packet boats between Cincinnati and Dayton, there is to be a new one established soon. Two of the boats, the *Richard Hans* and *Buffalo*, have already come down the Ohio river from Portsmouth, to take their places in the line, whenever the water in the locks will admit their passage up.

[From the Boston Atlas.]

**PUBLIC LANDS IN MAINE, No. 1.**—As the Timber Land mania is raging with such violence at this time, we have been induced to look a little into the subject, with the view of furnishing such information as might be interesting or important to our readers. We have been indebted for the following facts, to a series of articles, written by a gentleman thoroughly acquainted with the subject, and originally published in the Portland Advertiser.

About forty years ago, that tract of country now comprising the counties of York, Cumberland, Lincoln, Kennebec, and a little of the south part of Oxford, constituted the great Lumber Region of Maine. The whole country east of Lincoln and north of Kennebec, and the southern towns of Oxford, contained probably less than two thousand families. Machias was then an old establishment, and its lumber men had penetrated to some distance up the West and East rivers; but more than nine-tenths of their timber was still standing.—Quoddy contained about one hundred fishermen, but was to all intents an unknown land. "The rivers from there to St. George had hardly begun to strew sawdust in the way of the salmon." Logs had been brought down the Saggs from the Fryeburg and the Omisees, but no visible impression had been made on their immense forests. The

Presumpscot at that time had hardly floated a pine above Sebago lake. The more enterprising of the lumberers were beginning to bring logs down the Little Androscoggin, the then remote wilderness of Hebron. On the Great Androscoggin, the pine forests at any distance from the river were hardly touched higher than Lewiston. The Kennebec and its tributaries, as high up as Sandy river, had yielded a portion of their timber to the market.—But one hundred and thirty townships, of six miles square, would comprise all the territory on which any considerable quantity of pine timber had been cut in Maine. A very large portion of these were covered with dense forests of the best of pine, nine-tenths of which was still standing. In general this territory was even then as well timbered as any other part of the District.

The population of this tract was then about equal to that which is now in the counties of Penobscot and Somerset alone. To the men of that day, the timber within its limits seemed inexhaustible.—But where is it now? There is not a pine in the region large enough to tempt the axe of a Penobscot lumberman.

Since that day, and in some cases before, the lumberers have either been the pioneers of the agricultural settlers, or have followed immediately on their footsteps. No township has been long settled before destruction has overtaken its pine timber.— This destruction has been, and is still proceeding, in advance of the settlement, to an extent, and with a rapidity, that can hardly be credited. Since the period of which we have been speaking, about one hundred and fifty towns have begun and settled, and the timber, in those of them that contained any, is now wholly cut off. Besides these, there are one hundred additional townships; some of which are partly settled, and in all of which, containing any timber of consequence, the best and largest part of it is gone.

**RAILROAD ACCIDENT.**—On Monday afternoon, as the Locomotive and train of cars, from Saratoga to Ballston, came to where the old Saratoga road crosses the railroad, about half a mile east of the latter place, a one horse wagon, with a man and woman in it, stopped on the track; the engine came up at the moment, crushed the wagon, killed and mangled the woman in a shocking manner, and killed the horse—the man escaped unimpaired.

**IRISH RIOTS ON THE WARREN AND ERIE CANAL.**—Very serious riots have occurred on this Canal between two militant parties of the Irish employed in its construction. The *Corkonians* appear to have been the strongest, until the *Fardowns*, the rival faction, were reinforced, when both parties prepared for battle, and commenced arming with every thing they could lay their hands upon. Three kegs of powder were taken sordidly from a wagon on the road, and several citizens' houses were entered and robbed of muskets. A bloody battle was to have been fought between them on the 12th instant, the Anniversary of the Battle of the Boyne, but some volunteer companies from Fort Wayne and Logan's Fort, made their appearance, and Messrs. the *Corkonians* and the whole chivalry of the *Fardowns*, scampered like "brave Belgians." About one hundred were taken prisoners, and fourteen of the ringleaders, including Sullivan, a very active and conspicuous one of the number, were taken to Indianapolis, for safe custody. Quiet had been completely restored. [Con. & Eng.]

**STEAM ENGINES IN GLASGOW.**—To such an extent is the business of steam engine making now carried on here, that there are thirteen firms engaged in it. Some of the works are more like national than private undertakings. Three houses alone employ upwards of a thousand persons. Dr. Cleland has ascertained that in Glasgow and its suburbs there are thirty-one different kinds of manufactures where steam engines are used, and that in these, and in the collieries, quarries, and steamboats, there are 355 steam engines, equal to 7,366 horse power—average power of engines rather more than 20 horse each,—[Ency. Brit., 7th edition.]

*Improved Draft of the Hull of a Steam-boat.*

*Note.*—The dimensions and distances are not written, as the draft is drawn on a scale, viz., 32 feet to an inch.

**To the Editor of the Mechanic's Magazine:**

SIR,—The favorable reception you gave an article of mine in your last number, has induced me to offer the annexed draft of the hull of a steamboat, with an *elevated deck*, and an *arched or semi-circular bracing*, the objects of which are the more effectually to guard against the boat being thrown out of shape by the weight of the engine, boilers, &c., &c., and the depression of the bow and stern; or the necessity of building them with such heavy materials as to cause

them to draw too much water for extreme speed, or the navigation of shallow waters; added to which, the raising of the deck in the centre (in this draft two feet) not only enables light and air to be more easily introduced to the cabins, but also brings the upper surface immediately under the water-wheel shafts, which both passengers and engineers must admit is a very desirable improvement.

I had prepared a full explanation of the draft according to my views, but upon deliberation concluded that, to those who are competent to judge of it, any explanation that I could give would be superfluous, preferring to defend its merits, if doubted, either in person or through the same medium this is given; at the same time, with all due deference, challenging a refutation of its advantages or origin, with the writer, although I am well aware that on the latter ground I shall be met with the fact, that two boats lately built are now running, each of which have improvements somewhat similar to the above, but it is no less a fact, that the design from which this draft is taken was made by me twenty-one months since, which can be duly substantiated by a

YOUNG ENGINEER.

Aug. 10, 1835.

#### New Hydrometer—Query.

To the Editor of the Mechanics' Magazine:

SIR,—In June, 1831, the notice now enclosed ran the rounds of all the London papers. It reads "a piece of metal," but what metal is not stated. May I request you to say in your next, whether zinc, platina, copper, or any other? If you are not aware which kind, please desire information in your valuable work.

Respectfully, your reader,

ASMODEUS.

July 18, 1835.

"A NEW HYDROMETER.—A new instrument to measure the degrees of moisture in the atmosphere, of which the following is a description, has been recently invented by M. Baptiste Lendi, of St. Gall. In a white flint bottle is suspended a piece of metal about the size of a hazel-nut, which not only looks extremely beautiful, and contributes to the ornament of a room, but likewise predicts every possible change of weather 12 or 14 hours before it occurs. As soon as the metal is suspended in the bottle with water, it begins to increase in bulk, and in 10 or 12 days forms an admirable pyramid, which resembles polished brass, and it undergoes several changes till it has attained its full dimensions. In rainy weather this pyramid is constantly covered with pearly drops of water; in case of thunder or hail, it will change to the finest red, and throw out rays; in case of wind or fog, it will appear dull and spotted; and previously to snow, it will look quite muddy. If placed in a moderate temperature, it will require no other trouble than to pour out a common tumbler full of water and put in the same quantity of fresh."

Any of our friends or correspondents who will solve this question, will much oblige.

[From the London Mechanics' Magazine.]

#### ANTIS' IMPROVED CHIMNEYS.

SIR,—If the following paper, abridged from *Hazard's Register of Pennsylvania*, will tend at all to a discontinuance of the revolting practice of employing climbing boys in chimneys, I shall be happy to see it in your valuable and instructive publication.

Yours faithfully, A. Z.

To construct a chimney which would carry smoke has been found in practice one of the most precarious objects of mechanism. So little has the theory of smoke and draft been understood, that if ever a chimney was constructed to draw well, it was evidently a matter of accident; for no mechanic seemed to have any rule for constructing chimneys which would ensure a good one. We have been extremely gratified within a few days, by the inspection of a flue, and a set of fireplaces, constructed upon a plan entirely new in principle, invented by Mr. Henry Antis. We had not the pleasure of seeing Mr. Antis' model; but we saw the practical effect of his discovery, by a chimney and fireplaces in operation, in the house of Mr. Joseph Wallace, in Front street, the success of which is complete, and triumphantly sustains Mr. Antis' theory on the subject. His theory is, that cold atmospheric air tends to the centre of gravity, till it meets with some obstruction, which gives it another direction; that heated or magnified air is exactly vertical in motion; that hence, the flue to carry it off should be perfectly vertical, and in no place of smaller dimensions than at the bottom or first inlet. He maintains that it matters not how many inlets there be to it, provided the area of a cross section of the flue be equal to those of all the inlets combined; it may be greater, but must never be smaller. He therefore starts with a single flue from the cellar, regulating the size to cover the area of all the contemplated inlets from bottom to top. He carries it up all the way of the same size, in exact perpendicular direction; nor need the wall be more than the width of one brick in thickness. Wherever he wants a fireplace, he attaches jambs of the usual shape, leaving the common perpendicular wall of the flue for a back, throwing an arch across at the proper place in the usual form, covering it tight to the back wall. Immediately opposite or below the covering of the arch, he leaves a horizontal aperture in the flue, the whole width of the fireplace, from jamb to jamb, in size according to calculation previously made, and according to the height of the arch, which, for jambs from twenty-four to thirty inches high, must not be less than three inches perpendicular in the opening.

There seems to be philosophy in this theory; and practice, so far as tried, proves that there is truth in it; and we have no doubt the plan will, on a little further trial, be universally adopted by builders.

Beneath each grate, fitted in a fireplace, is an opening left, which descends

obliquely into the flue. In this opening, on a level with the hearth, is a fire grate fixed, through which the ashes descend from the grate above. And such is the effect, that while a strong current of air is produced by the heat from the fire in the grate, through the horizontal aperture above, a moderate draught is also maintained in the oblique one below, which carries off all the dust; so that from a coal fire not a particle of dust escapes into the room. He also affixes a valve to each inlet, hung in such an ingenious manner, that the mere pulling of a small brass knob closes it entirely; and thus, in case the chimney should take fire, all the currents of air may be stopped in a moment, and the fire dies at once. Not a particle of soot can ever enter your room or your fireplace; for that, as well as the ashes, all descend to the bottom of the flue in the cellar, where an opening, with a sheet iron door, is constructed, from which these articles can be taken, and through which a sweep may enter and perform his duties, without disturbing the business, or amusements, or quiet, of any part of the family. Where necessary, he also carries up side flues in the jambs, by which air can be introduced, to regulate the temperature of your room, or the force of your draughts.

The advantages of this improvement are,

- 1st. Fewer materials are used, which cheapens the work.
- 2d. Less room is engrossed by dead brickwork.
- 3d. No annoyances from soot or ashes in your rooms—not even when a sweep ascends to clean out your flue.
- 4th. Power to regulate the temperature of your rooms, without opening doors or windows.
- 5th. Perfect security against smoke in every room in your house.

#### AGRICULTURE, &c.

This communication, together with another, from an esteemed correspondent, both received in time, was by some means mislaid at the proper period for publication; they are both from practical men, and of much consequence to other practical men, although somewhat out of season for this year, to be omitted entirely—and we therefore give them now, trusting to the good memory of those who may be benefitted by them to apply them next year.

East Lyme, Giant's Neck, April, 1835.

To the Editor of the New-York Farmer:

SIR,—Living retired in a dark corner of the world, I have seen your paper the last winter, and find many valuable rules in farming in your paper; I will give you a plan of planting potatoes. If you think it worth publishing, I have no objection.

The first thing get your ground well prepared by ploughing, it should be mellow and soft, I think twice ploughing preferable. Then spread your manure on the furrows from ten to twenty or thirty loads to the acre, just as you have it to spare, then take a large iron tooth harrow, and harrow the

manure well into the ground as well as possible; then furrow your ground with an old fashion Dutch plough, if you have one without any share, just to make a mark, say two inches deep. I prefer large potatoes for planting, they should be cut into two or three pieces, calculating to have three good eyes on a piece, plant one piece in a hill, calculating to have your rows two and a half feet apart, and eighteen inches between hills.

The reason I have for cutting potatoes is this, a small or middling size potatoe has, many times, as many eyes as a large one. Therefore when you plant them, you have too many shoots in a hill, and these increase your number of potatoes, and not the quantity, but rather diminish the quantity; in planting the large ones cut, you have a greater quantity, and better quality, they are more sizeable or larger. Potatoes are much better to grow top of the ground, they produce better, the quality is better, and much less labor to raise them; potatoes should have a sharp peaked hill, when you hill them up the last time. The plan is simple, I recommend farmers to try it.

Respectfully yours,  
G.

[From the Tennessee Farmer.]

**SAVING CLOVER SEED.**—The two great objects to be attended to, in raising clover seed with profit, are—first, to secure the production of as large a crop to the acre as practicable—and secondly, to harvest the crop in such a manner as to bring as large a portion of the seed into the barn and to leave as small a portion of it as possible in the field.

To attain the first object, that of securing a large product, we have in our preceding numbers, in observations on the culture of clover, given the necessary directions, we will now only repeat, that the main things to be attended to are the following:—1st, That the land be fertile. 2d, That it be well prepared before sowing the seed, as heretofore directed. 3d, That a sufficient quantity of seed be sown to the acre. 4th, That it be evenly distributed over the ground. 5th, That whenever the land requires its aid, gypsum or plaster be sown on the clover. And 6th, That it be not injured by injudicious or excessive grazing. If these particulars be well attended to, an acre of ordinary land will produce three bushels of seed in a common season, often more.

We now come to speak of the more difficult and laborious operation of safely and economically harvesting and securing it. This requires care and attention. The great objects to be aimed at are, to cut the seed at the period when there is the largest portion of ripe seed on the ground, in that stage of maturity which will admit of its being collected into the barn, and so to handle it as to prevent the seed from being shattered off and left on the field, while straw or baulm only is collected in the barn. It is, we believe, to the improvident and ruinous neglect of strict attention to these two latter objects, that most farmers may attribute their failure in making clover seed. We will lay before our readers the results of our own observation and experience on these important points, hoping that those of our patrons, who may have discovered a better mode of effecting these objects than the one recommended, will yet communicate to us their practice in time to enable us to lay it before the public in our next number.

**Time of Cutting.**—As the clover seed, from the time the first heads ripen, until the close of the season, are daily arriving

at maturity, the great desideratum is to ascertain the precise period when there is on the ground the greatest portion of ripe seed in a state which will admit of its being collected and brought into the barn. If the clover be cut before this period, there must evidently be a loss sustained, from the immaturity of too large a portion of the seed. If the cutting be deferred beyond this period, an equal, and perhaps a greater loss, will be sustained, from the impossibility of saving the seed first ripened, generally the best, on account of its being so easily shattered off. We would recommend, as the most eligible time for cutting, the period when about two thirds of the heads have become ripe and assumed a black color, many of the others, at this time of a brown color, will ripen after cutting.

**Mode of Cutting.**—Where the clover has not flooded, and is high enough to admit of it, by far the most expeditious, and in every point of view the most eligible mode of cutting, is to cradle it as we do grain, only throwing it into double swarths, that is laying the clover cut from two lands in one swarth. If the grass be so short as to require it, a strip of linen may be fastened on the fingers of the cradle so as to prevent the heads falling through them.

**Mode of Curing.**—If this crop be not heavy and the weather be good, the swarths may lie undisturbed for several days, until the hay be perfectly cured; it should then, in the morning or evening, while sufficiently moist from the dew, to prevent its shattering off too easily, be gently raked into small bunches, such as can be conveniently raised with a fork and laid on the wagon. When not too damp, these bunches should be hauled to the barn, and either stowed away in mows, or, which is best, threshed off, and either immediately cleaned, or else the heads stowed away in a room prepared for the purpose until winter, to be then threshed or trodden out. But should there be rain on them, or should they be suffered to remain in the field any considerable length of time after being raked up, these bunches must with a fork be gently turned bottom upwards, and laid in a new place, after every rain to which they may be exposed, and after every two or three days they may have lain in the field in fair weather. This is necessary to prevent the seed from being injured by the heat and moisture to which they will have been exposed, from the sun, the rain, and the moisture of the earth. After being sufficiently cured, while dry, let the seed be gently laid on the wagon or sled, and hauled to the barn, using every necessary precaution to ensure that as little of it as possible be left in the field or scattered along the road.

**Mode of Cleaning.**—Various methods are practised for cleaning the seed from the chaff. The only two as far we know used in this country, are treading it out with horses, or cleaning it in a threshing machine: the first is tedious, laborious, filthy and unwholesome, both to man and beast, the latter is far preferable in every respect, but as all are not provided with threshing machines, and as therefore many must still continue to tread out their seed, we will submit a few observations on the mode of performing this operation. Having covered the barn floor with seed in the chaff to the depth of from 12 to 18 inches, put on the horses and tread one day, the next morning run the chaff through a fan, much of it will have been beaten to dust and will be blown away, as will also the light chaff having no seed, and that from which the seed has been separated,

but much the larger portion of the seed, still enveloped in the chaff, will be found in the rear of the fan; this, having been separated from the empty chaff adjoining it, must be again spread on the floor, and having added another portion of untrodden chaff, the horses must be again put on and made to tread it another day, when it should be again run through the fan as before; the produce of this will far exceed that of the first day's treading, but still much good seed will be found immediately in the rear of the fan not yet separated from the chaff—this must be again spread on the floor, and a new addition be made of untrodden chaff, and this process must be repeated until the whole crop is trodden out. The seed, after passing through the fan, should first be run through a sieve, sufficiently coarse to permit the clover seed to pass through, but retaining all larger seeds and trash. It should then be again run through a finer sieve, retaining the clover seed, but permitting the passage through of all smaller substances; by these two processes, the clover seed will be thoroughly cleansed from all kinds of filth and prepared for market. The only advantages derived from cleaning the seed rather than sowing it in the chaff, are the ascertaining with greater certainty the quantity sown and the ensuring a more equal distribution of the seed—where, therefore, a sufficient quantity can be afforded to ensure the desired thickness in, every part of the ground, sowing in the chaff will not only do as well, but it to be preferred, as it is believed more likely to come up and to stand.

In reply to our correspondent's 3d query, as to the time of ploughing under clover for wheat, we would recommend that it be done so soon as a considerable portion of the seed has become ripe—the wheat should then be sown and well harrowed in, but the land should by no means be again ploughed, until the wheat has been taken off.

As to briars and sedge grass, we refer our subscriber to what we have said in former numbers, and in the present—the sedge grass he will find easily subdued, if the ground be ploughed and harrowed in the winter; pasturing and deep ploughing are the only effectual modes we have tried for extirpating briars and sprouts, we have much confidence however in the efficacy of the mode described in the receipt published in this number.

Harmon's threshing machine will thresh out, if properly attended to, from five to ten bushels of clover seed, and from 150 to 200 bushels of wheat per day. This machine will cost about fifty dollars, exclusive of the house and millwright's work; this is the only machine for cleaning clover seed used in this part of the country—of which we are apprised; we have used it for two years past with great advantage, especially in cleaning clover seed.

[From Hovey's Gardener's Magazine.]

*Notices of some of the Gardens and Nurseries in the Neighborhood of New-York and Philadelphia; taken from Memoranda made in the Month of March last.*  
By C. M. H.

THE ESTABLISHMENT OF MR. G. C. THORBURN, SEEDSMAN AND FLORIST, in Liberty street; (formerly the property of our excellent correspondent, now of Hallett's Cove.) demands mention for its judicious and tasteful arrangement, and for the fine variety of plants it contains. All

though not so much attention may be given to their growth, as in nurseries where the cultivation of plants is the sole business of the proprietor, still they have the appearance of strength and health, and well fitted for exportation to various parts of the country.

It is now upwards of thirty years since our correspondent, Grant Thorburn, Esq., first commenced the business of a seedsmen in New-York. After a series of years of toil and labor, in endeavoring to establish himself and his business in the confidence of the public, he was subjected to the great loss of nearly all his property, which was destroyed by fire. A few years afterwards he was also nearly ruined by his attempting to raise seeds, which could not be imported, in consequence of the late war. This expensive method of procuring seeds in this country, with the little knowledge of their growth at that time, could not otherwise than prove an unprofitable and fruitless attempt; he however again resumed his former business, and by the help of friends was enabled to establish the foundation of what the establishment now is. Mr. Thorburn's sons were, a few years since, connected with him in the business; one of them left, and it was carried on by himself and eldest son. Mr. Thorburn has lately retired from the business altogether, and given it up to his son, Mr. G. C. Thorburn, who now conducts the whole.

We have been thus particular in mentioning these facts, although they may be already well known to most of our readers, for many reasons; the first of which is, that we cannot but think the establishment of such a place, in the very centre of so large and populous a city as New-York, and at a time when gardening was little known, has been of exceedingly great importance in spreading, and much more extensively diffusing, a general taste for floricultural pursuits. The nursery of the Messrs. Prince, on Long Island, and of others in Philadelphia, date their origin at a much earlier day, but they are not situated where the public could have that easy access to them that they have had at this place. We have no hesitation in saying, that this establishment has tended as much toward the dissemination of a taste for gardening pursuits, as any nursery or garden in our country. Who has not noticed Lawrie Todd, as our correspondent still styles himself, in the various papers and periodicals of which he is a frequent contributor? Who has not listened to his oft-told story of his first landing upon the shores of our country—of his future success—of his great, if it cannot be called lucky, success in acquiring a competent fortune; few indeed there are, especially those interested in Horticulture, who have visited, or passed through New-York, who have not availed themselves of the opportunity of walking through the establishment of the Messrs. Thorburn.

This place, as most of our readers are probably aware, has lately been sold for an immense sum of money, realizing al-

most a fortune to its former owner. It is soon to be razed to the ground, and the place, which has long been the resort of the horticulturist and the florist—where for many years the gorgeous tulip has arrayed itself, and the hyacinth given out its fragrant odor, where the dahlia, the pride of the autumn, has reared its magnificent head, and where even winter appeared with not half its rigors, by the continuous bloom of the snowy white Camellia, through the dreary weather,—is to be built up with blocks of stores or dwellings. The value of land in New-York will soon cause every garden, as it has nearly already, to be removed without the city.

In the green-house we did not find many flowers in bloom; here, as well as at Mr. Hogg's, an immense number of bouquets of flowers are cut throughout the winter, and more particularly in the months of February and March. We saw, however, in flower, *Amaryllis formosissima* and some other species. *Camellia japonica*, var. *imbricata*, was splendidly in flower: we believe this was the only place where we observed it in bloom during our visit. It has since flowered at Col. Perkins', in Brookline, and also in our garden. It is one of the finest of *Camellias*; it is figured in Chandler's illustrations of the *Camellia*, and in the Botanical Register; in the former, the flower is represented of a deep crimson color, and is stated as occasionally being striped with white; in the latter, it is striped or edged with white, exactly the same as the three different plants which we have had the opportunity of seeing. It is rather singular that it should have been described as being of a deep crimson color: the plant at Col. Perkins' had several flowers upon it, all of which were nearly alike. Here were also fine large plants of *C. variegata*, *C. incarnata*, and others with several flowers expanded. Mr. Thorburn's stock of *camellias* is large, and contains a fine variety; we noticed among the rest, *colvillii*, *reticulata*, *eximia*, &c. Here were some fine plants of *Magnolia grandiflora* raised from seed; *Pandanus* (sp.?) and large American aloes. Mr. Thorburn, sen., when he was last in England, brought home several vases, which, in March last, ornamented the green-house. Two plants of *Ardisia colorata*, were growing in two of them; the largest plant of the Indian rubber tree (*Ficus elastica*) we have ever seen, was growing at this place. It is a most admirable plant, and few are aware of its great beauty when plunged out in the border, or if large plants, placed in vases, and set upon the lawn, or among the shrubbery of the flower garden; its large, strong, thick, fleshy, and deep-green leaves, have a noble appearance; it is also a fine ornament to the green-house or conservatory. *Pæonia moutan*, var. *Banksii*, was in flower, with several blossoms expanded; several pots of *lachenalias*, and *hyacinths* were in full bloom. We here observed several plants, of a species of beet, which are grown for the beauty of their leaves and footstalks,

some of which are of a bright yellow, and others of a deep crimson. Many other plants we noted down, but as they were not in flower, our enumeration of them would not be of interest to our readers. We have lately understood that Mr. G. C. Thorburn intends removing early in the fall; to what place we are not informed.\*

**NURSERY OF MESSRS. SHAW & THORBURN, HALLET'S COVE, LONG ISLAND.**—This nursery has been established within a few years. It is about twenty acres in extent, and situated near the landing of the ferry at Hell-Gate; the distance, we believe, of about five or six miles from the city. It was first established under the direction of Mr. John Thorburn, who erected a large and extensive green-house, and also one or two smaller ones, for the forcing of flowers for the purpose of cutting bouquets during winter, with which he supplied (and still continues to) his brother in New-York. About a year since, Mr. Shaw, formerly of the old Botanic Garden, was taken in a partner, and the business is now conducted in their name.

Their collection of plants is quite large, and embraces many fine and choice kinds. In *camellias* and *geraniums* they are very rich; they have, also, a fine collection of *amaryllises*, including many of the seedlings raised at Colville's. Among the *camellias* we saw in flower, varieties *florida*, *coccinea*, (*Alnuds splendens*), *variegata*, *Woodsii*, *incarnata alba plena*, *compacta*, *anemoneflora alba*, and a kind supposed *concinna*; the latter was extremely beautiful; but the label having been lost, or accidentally exchanged, it was misnamed. There was here a good stock of *rhododendrons* and *azaleas* of the newer kinds, including the *R. altacelerence*, *morterii*, *Russellianum*, &c. The green-house is divided by a glass partition, and one part is kept at a considerable higher temperature than the other, answering the purpose of a hot-house or stove. In this we observed that curious and singularly beautiful plant the Canary bird flower, (*Tropæolum peregrinum*), covered with its copious wreaths of flowers; this plant, like many other twiners or climbers, is remarkable for the footstalks of its leaves, answering the purpose of tendrils; it quickly attaches itself to any thing in its way, and often attains to a great height: we should think that this plant extended several feet, and had open several hundred flowers. We mentioned this plant not long since (204) as being in bloom in Mr. R. Buist's, Philadelphia. We then gave it the specific name of *pentaphyllum*, with some observations on a new genus, &c. We wrote from memory without any reference, and inadvertently fell into this error: it will be found corrected in the present number, in our notices of new plants. We again state that it is easily propagated from cuttings or seeds, and that it is deserving a place in every green-house. Among the *amaryllises* we observed in flower John-

\* He has removed to John st., near Broadway.

sonia, venusta, and several other equally beautiful kinds. Here was a good stock of the cacti, and we noticed a plant of *C. mallisoni*, a splendid new hybrid. We observed many other fine things in the stove compartment, but want of time prevented our making a memorandum of them.

In a small pit or green-house adjoining the larger one, we observed a large number of roses, and flowers in bloom, for cuttings for bouquets. In this were placed several camellias which had been budded the preceding fall, and had taken well. The method of budding was different from that in general use: the bud is prepared by taking off a piece of the bark with the bud attached, cutting it exactly of the same size as the piece taken out of the stock, in order that the edges may meet as close as possible. The size of the bud will vary according to the strength of the wood; but in general it should be about half or five-eighths of an inch in length, and one or two eighths in breadth: the whole should be covered with grafting wax, as bass matting alone will not keep the air from the bud. This method answers very well for increasing the camellia, the wood of which is so hard, that the old method of inserting the bud under the bark cannot be performed with much certainty. We here observed *Erica baccans*, with its elegant tufted heads of rosy-colored flowers, in full bloom; the common *Keria japonica* was flowering, trained to the back wall. *Lupinus mutabilis*, that new splendid annual, was throwing up spikes of flowers; the plants were taken from the flower border, and placed in pots, early in the fall, our summers being scarcely long enough for it to open its flower buds in the open air; its changeable flowers are extremely showy. There was also here a fine stock of that gem of the garden we have so frequently noticed, the *Petunia phoenicea*. Messrs. Shaw & Thorburn's gardener appeared very industrious and well informed, and the plants under his care looked exceedingly well.

**TO DESTROY THE CANADA THISTLE.**  
—Cut them off near the ground, when they are full in the blow or a little past. This process I have tried for three years, and find that it entirely eradicates them from the fields by once mowing. I have noticed several modes of destroying this noxious weed in the Cultivator, but find none attended with so small expense as mine, which has induced me to send you the above. **SOLOMON W. JEWETT.**  
Weybridge, Vt., July 23, 1835.

**Remark.**—In confirmation of the above, we can state, that in 1834 we unexpectedly found a quarter of an acre of rank thistles in a piece of grass ground recently laid down. They were in full bloom when the grass was mown. The present year, the number was apparently diminished five-sixths, and what remained were stunted dwarf plants. The thistle spreads most in ploughed ground and in highways, where they are rooted among by the hogs.—[Cultivator.]

**THE GENESSEE FLATS.**—We have often heard of the extraordinary fertility of these fine lands; but the annexed paragraph from the *Mount Morris Spectator*, even exceeds our previous conceptions of the extent of that fertility.

**GOING AHEAD!**—Mr. Editor: Please give the following a place in your paper for the benefit of the Genessee Valley farmers: Messrs. Geo. and Philo Mills have harvested this season, from twenty-seven acres of the Genessee Flat lying near this village, 1,270 bushels of wheat; threshed, cleaned, and delivered the same to B. & J. Campbell, in four days, for one dollar per bushel. Can the far-famed "West," beat this.

Forty-seven bushels of clean wheat to the acre, and that not in a small field of two or three acres, but for 27 acres, cannot, we may well believe, be exceeded, either in the "far famed West," or elsewhere.

We may add, that this is part of the land offered for sale, in the columns of this paper, by B. W. Rogers.

To the Editor of the New-York American.

Dear Sir,—I observe in the American of last evening, an article taken from the *Mount Morris Spectator* of 20th August, in which it is stated that on 27 acres of the Genessee Flats, P. & G. Mills, who are tenants of mine, had raised this season 1270 bushels of wheat, being 47 bushels per acre.

As this appears to have excited your surprise, and as the *Mount Morris Editor* has pleasantly challenged the "far West" to beat it, and as the fine lands of the Genessee Valley, at a distance from the great travelled road, are too little known, permit me to state some additional facts respecting them.

Mount Morris is in Livingston County, six miles beyond Genesee. When there in July last, General Mills informed me that from 80 acres of the Mount Morris Flats, lying in one body, he raised the last year 3,200 bushels of wheat of best quality, and that it was accurately measured under his own inspection, being 40 bushels per acre.

The 27 acres are not of superior quality to the adjoining flats, and not equal to some of the Leicester flats on the opposite side of the Genessee river. As in your notice of the above you refer to these, as being some of the lands advertised for sale by me in your country paper, permit me to state, that, on farm No. 1, containing 400 acres, lying in Leicester, there are at least 350 acres, in every respect equal to, and on farm No. 2, containing 170 acres, more than half is superior, in quality to the above 27 acres.

From 170 acres lying in one body in number one, Dr. Wm. C. Dwight, the present tenant, raised two years since, twelve thousand eight hundred bushels of shelled corn, being upwards of 75 bushels per acre; and on number two, in the summer of 1834 he had 20 acres in wheat, in one body, which averaged 48 bushels per acre; two acres of the best of which he measured off, and of these the produce was 52 bushels per acre.

The editor states that the 1270 bushels of wheat were threshed, cleaned, and delivered in four days. It is customary on these flats to have the thrashing machines taken to the stacks of wheat on the field, by which much labor and time are saved. Some of the large farmers there also make use of machines for cutting the grain, which are moved by horse power. With one of these, one man, with a pair of horses, can cut 12 to 15 acres of wheat between sun-rise and sun-set. The wheat as cut falls upon a platform, and connected with the machine is a revolving rake, which takes the grain from the platform, and places it on the ground precisely in the proper quantity for a sheaf; and though all that is required of the binder, is to make the bands, and bind up the sheaves, I have seen nine active binders busily employed in keeping up with the cutting machine. The work is done with not one-fourth the waste of grain, which takes place in the usual mode of cradling or reaping.

These machines of course are only calculated for fields, free from stumps and brushwood, and cost about 160 dollars each.

If you think this communication of sufficient importance to interest your readers, do with it as you please. Yours, respectfully,

B. WOOLSEY ROGERS.

NEW-YORK AMERICAN.

AUGUST 29—SEPTEMBER 5, 1835.

**DISCOVERIES IN THE MOON.**—We commence to-day, and will finish to-morrow, the republication, from one of the penny papers, the *Sun*, of a narrative of discoveries, which has the merit of great talent and unquestionable originality. Few things of the sort have been more successful in making their way to general belief—and if scepticism afterwards came in with its cold doubts, the ready believers could not but feel with certainty that they had, at least, been delighted.

We believe both the narrative and the discoveries are the production of this city, and they certainly evince knowledge, fancy, and acquirements, of a high order. We congratulate the *Sun* upon having such a coadjutor.

Great Astronomical Discoveries.

Lately made by Sir John Herschel, L. L. D., F. R. S. &c. at Cape of Good Hope.

[From the Supplement to the Edinburgh Journal of Science.]

In this unusual addition to our Journal, we have the happiness of making known to the British public, and thence to the whole civilized world, recent discoveries in Astronomy which will build an imperishable monument to the age in which we live, and confer upon the present generation of the human race proud distinction through all future time. It has been poetically said that the stars of heaven are the hereditary regalia of man as the intellectual sovereign of the animal creation. He may now fold the Zodiac around him with a loftier consciousness of his mental supremacy.

It is impossible to contemplate any great Astronomical discovery without feeling closely allied to a sensation of awe, and nearly a kin to those with which a departed spirit may be supposed to discover the unknown realities of a future state.—Bound by the irrevocable laws of nature to the globe on which we live; creatures, "close shut up in infinite expanse;" it seems like acquiring a fearful supernatural power when any of the remote and mysterious works of the Creator yield tribute to our curiosity. It seems almost a presumptions usurpation of powers denied us by the divine will, when man, in the pride and confidence of his skill, steps forth far beyond the apparently natural boundary of his privileges, and demands the secrets and familiar fellowship of other worlds. We are assured that when the immortal philosopher to whom mankind is indebted for the thrilling wonders now first made known, had at length adjusted his new and stupendous apparatus with a certainty of success, he solemnly paused several hours before he commenced his observations, that he might prepare his own mind for discoveries which he knew would fill the minds of myriads of his fellow men with astonishment, and secure his name a bright if not transcendent conjunction with that of his venerable father, to all posterity. And well might he pause! From the hour the first human pair opened their eyes on the glories of the blue firmament above them, there has been no accession to human knowledge at all comparable in sublime interest to that which he has been the honored agent in supplying; and we are taught to believe that, when a work, already preparing for the press, in which his discoveries are embodied in detail, shall be laid before the public, they will be found of incomparable importance to some of the grandest operations of civilized life. Well might he pause! He was about to become the sole depository of wondrous secrets which had been hid from the eyes of all men that had lived since the birth of time. He was about to crown himself with a diadem of knowledge which would give him a conscious pre-eminence above every individual of his species who then lived, or who had lived in the generations that are passed away. He paused ere he broke the seal of the casket which contained it.

To render our enthusiasm intelligible, we will state at once that by means of a telescope, of vast dimensions, and an entirely new principle, the younger Herschel, at his observatory in the Southern Hemisphere, has already made most extraordinary discoveries in every planet of our solar system; has discovered planets in other solar sys-

tems; has obtained a distinct view of objects in the moon, fully equal to that which the unaided eye commands of terrestrial objects at the distance of a hundred yards; has affirmatively settled the question whether this satellite be inhabited, and by what order of beings; has firmly established a new theory of cometary phenomena; and has solved or corrected nearly every leading problem of mathematical astronomy.

For our early, and almost exclusive, information concerning these facts, we are indebted to the devoted friendship of Dr. Andrew Grant, the pupil of the elder, and for several years past the inseparable coadjutor of the younger Herschel. The amanuensis of the latter at the Cape of Good Hope, and the indefatigable superintendent of his telescope during the whole period of its construction and operations, Dr. Grant has been enabled to supply us with intelligence, equal in general interest at least to that which Dr. Herschel himself has transmitted to the Royal Society. Indeed our correspondent assures us that the voluminous documents now before a committee of that institution contain little more than details and mathematical illustrations of these facts communicated to us in his own ample correspondence. For permission to indulge his friendship in communicating this invaluable information to us, Dr. Grant and ourselves are indebted to the magnanimity of Dr. Herschel, who, far above all mercenary considerations, has thus signally honored and rewarded his fellow laborer in the field of science. The following engravings of lunar animals and other objects, and of the phases of the several planets, are accurate copies of drawings taken in the observatory by Herbert Home, Esq. who accompanied the last powerful series of reflectors from London to the Cape, and superintended their erection; and he has thus recorded the proofs of their triumphant success. The engraving of the belts of Jupiter is a reduced copy of an imperial folio drawing by Dr. Herschel himself, and contains the results of his latest observation of that planet. The segment of the inner ring of Saturn, is from a large drawing by Dr. Grant.

We first avail ourselves of the documents which contain a description and history of the instrument by which these stupendous discoveries have been made. A knowledge of the one is almost essential to the credibility of the other.

#### THE YOUNGER HERSCHEL'S TELESCOPE.

It is well known that the great reflecting telescope of the late elder Herschel, with an object glass four feet in diameter, and a tube forty feet in length, possesses a magnifying power of more than six thousand times. But a small portion only of this power was ever advantageously applied to the nearer astronomical objects; for the deficiency of light from objects so highly magnified, rendered them less distinct than when viewed with a power of a third or fourth of this extent. Accordingly the powers which he generally applied when observing the moon and planets, and with which he made his most interesting discoveries, ranged from 220, 460, 750, and 900 times; although when inspecting the double and treble fixed stars, and the more distant nebulae he frequently applied the full capacity of his instruments. The law of optics, that an object becomes dim in proportion as it is magnified, seemed, from its exemplification in this powerful telescope, to form an insuperable boundary to further discoveries in our solar system. Several years, however, prior to the death of this venerable astronomer, he conceived it practicable to construct an improved series of parabolic and spherical reflectors, which, by uniting all the meritorious points in the Gregorian and Newtonian instruments, with the highly interesting achromatic discovery of Dolland, would, to a great degree, remove the formidable obstruction. His plan evinced the most profound research in optical science, and the most dexterous ingenuity in mechanical contrivance; but accumulating infirmities, and eventually death, prevented its experimental application. His son, the present Sir John Herschel, who had been nursed and cradled in the observatory, and a practical astronomer from his boyhood, was so full convinced of the value of the theory, that he determined upon testing it at whatever cost. Within two years of his father's death, he completed his new apparatus and adapted it to the old telescope with nearly perfect success. He found that the magnifying power of 6000 times, when applied to the moon, which was the severest criterion that could be selected, produced, under these new reflectors, a focal object of exquisite distinctness, free from every achroma-

tic obscurity, and containing the highest degree of light which the great speculum could collect from that luminary.

The enlargement of the angle of vision which was thus acquired, is ascertained by dividing the moon's distance from the observatory, by the magnifying power of the instrument; and the former being 240,000 miles, and the latter 6000 times, leaves a quotient of 40 miles, as the apparent distance of that planet from the eye of the observer. Now it is well known that no terrestrial objects can be seen at a greater distance than this, with the naked eye, even from the most favorable elevations. The rotundity of the earth prevents a more distant view than this with the most acute natural vision, and from the highest eminences; and, generally, objects seen at this distance, are themselves elevated on mountainous ridges. It is not pretended, moreover, that this forty miles telescopic view of the moon presented its objects with equal distinctness, though it did in equal size to those of this earth so remotely stationed.

The elder Herschel had nevertheless demonstrated that with a power of 1,000 times he could discern objects in this satellite of not more than 122 yards in diameter. If therefore the full capability of the instrument had been elicited by the new apparatus of reflectors constructed by his son, it would follow in mathematical ratio that objects could be discerned of not more than 22 yards in diameter. Yet in either case they would be seen as mere feeble, shapeless points, with no greater conspicuity than they would exhibit upon earth to the unaided eye at the distance of forty miles. But although the rotundity of the earth presented no objection to a view of these astronomical objects, we believe Sir John Herschel never insisted that he had carried out these extreme powers of the telescope in so full a ratio. The deficiency of light, though greatly economized and concentrated, still maintained some inverse proportion to the magnitude of the focal image.—The advance he had made in the knowledge of this planet, though magnificent and sublime, was thus but partial and unsatisfactory. He was, it is true, enabled to confirm some discoveries of former observers, and to confute those of others.—The existence of volcanoes discovered by his father and by Schroeter of Berlin, and the changes observed by the latter in the volcano in the *Mare Crisium*, or Lucid Lake, were corroborated and illustrated, as was also the prevalence of far more extensive volcanic phenomena. The disproportionate height attributed to the lunar mountains—whilst the celebrated conical hills, encircling valleys of vast diameter, and surrounding the lofty central hills, were distinctly perceived. The formation which professor Fraunhofer uncharitably conjectured to be a lunar fortification, he ascertained to be a tabular buttress of a remarkable pyramidal mountain; lines which had been whimsically pronounced roads and canals, he found to be keen ridges of singularly regular rows of hills—and that which Schroeter imagined to be a great city in the neighborhood of *Maurius*, he determined to be a valley of disjointed rocks scattered in fragments which averaged at least a thousand yards in diameter. Thus the general geography of the planet, in its grand outlines of cape, continent, mountain, ocean and island, was surveyed with greater particularity and accuracy than by any previous observer; and the striking dissimilarity of many of its local features to any existing on our own globe, was clearly demonstrated. The best enlarged maps of that luminary which have been published, were constructed from this survey; and neither the astronomer nor the public ventured to hope for any great accession to their developments. The utmost powers of the largest telescope in the world had been exerted in a new and felicitous manner to obtain them, and there was no reasonable expectation that a larger one could ever be constructed, or that it could be advantageously used if it were. A law of nature, and the finitude of human skill, seemed united in inflexible opposition to any farther improvement in telescopic science, as applicable to the known planets and satellites of the solar system. For unless the sun could be prevailed upon to extend a more liberal allowance of light to these bodies, and they be induced to transfer it for the generous gratification of our curiosity, what adequate substitute could be obtained? Telescopes do not create light, they cannot even transmit unimpaired that which they receive. That any thing fur-

ther could be derived from human skill in the construction of instruments, the labors of his illustrious predecessors, and his own, left the son of Herschel no reason to hope. Huygens, Fortina Gregory, Newton, Hadley, Bird, Short, Dolland, Herschel, and many others, all practical opticians, had resorted to every material in any wise adapted to the composition either of lenses or reflectors; and had exhausted every law of vision which their study had developed and demonstrated. In the construction of his last amazing specula Sir John Herschel had selected the most approved amalgams that the advanced stage of metallic chymistry had combined; and had watched their growing brightness under the hands of the artificer with more anxious hope than ever lover watched the eye of his mistress: and he has nothing further to expect than they had accomplished. He had the satisfaction to know that if he could leap astride a cannon ball and travel upon its wings of fury for the respectable period of several millions of years, he would not obtain a more enlarged view of the distant stars, than he could now possess in a few minutes of time; and that it would require an ultra-rail road speed of 50 miles an hour, for nearly the live long year, to secure him a more favorable inspection of the gentle luminary of night. The interesting question, however, whether this light of the solemn forest, of the treeless desert, and of the deep blue ocean as it rolls; whether this object of the lonely turret, of the uplifted eye on the deserted battle field, and of all the pilgrims of love and hope of misery and despair, that have journeyed over the hills and valleys of this earth, through all the eras of its unwritten history to those of its present voluminous record; the exciting question whether this "observed" of all the sons of men, from the days of Eden to those of Edinburgh, be inhabited by beings, like ourselves, of consciousness and curiosity, was left for solution to the benevolent index of natural analogy, or to the severe tradition that it is tenanted only by the hoary solitudes whom the criminal code of the nursery had banished thither for collecting fuel on the sabbath day.

The limits of discovery in the planetary bodies, and in this one especially, thus seemed to be immutably fixed: and no expectation was elevated for a period of several years. But, about three years ago, in the course of a conversation with Sir David Brewster upon the merits of some ingenious suggestions by the latter, in his article on optics in the Edinburgh Encyclopedia, (p. 644,) for improvements in the Newtonian Reflectors, Sir John Herschel adverted to the convenient simplicity of the old astronomical telescopes that were without tubes, and the object glass of which, placed upon a high pole, threw its focal image to a distance of 150, and even 200 feet. Dr. Brewster readily admitted that a tube was not necessary, provided the focal image were conveyed into a dark apartment, and there properly received by reflectors. Sir John then said, that if his father's great telescope, the tube alone of which, though formed of the lightest suitable materials, weighed 3000 lbs., possessed an easy and steady mobility with its heavy observatory attached, an observatory moveable without the incumbrance of such a tube was obviously practicable. This also was admitted, and the conversation became directed to that all-invincible enemy, the paucity of light in powerful magnifiers. After a few moments silent thought, Sir John distinctly inquired whether it would not be possible to effect a transference of artificial light through the focal object of vision! Sir David, somewhat startled at the originality of the idea, paused awhile, and then hesitatingly referred to the infrangibility of rays, and the angle of incidence. Sir John, grown more confident, adduced the example of the Newtonian Reflector, in which the infrangibility was corrected by the second speculum, and the angle of incidence restored by the third. "And," continued he, "why cannot the illuminated microscope, say the hydro-oxygen, be applied to render distinct, and if necessary, even to magnify the focal object?" Sir David sprang from his chair in an ecstasy of conviction, and leaping half-way to the ceiling, exclaimed "Thou art the man." Each philosopher anticipated the other in presenting the prompt illustration that if the rays of the hydro-oxygen microscope passing through a drop of water containing the larvae of a gnat, and other objects invisible to the naked eye, rendered them not only keenly distinct, but firmly magnified to dimensions of many feet; so could the same artificial light, passed through the faintest focal object of a telescope, both distinctly, (to coin a new word for

the extraordinary occasion) and magnify, its feeble component members. The only apparent desideratum was a recipient for the focal image which should transfer it without infringing it, to the surface on which it was to be viewed under the varying light of the microscopic reflectors. In the various experiments, made during the few following weeks, the co-operative philosophers decided that a medium of the purest plate glass (which is said they obtained, by consent, be it observed, from the shop window of Mons. Desanges, the jeweller to his ex-majesty Charles X., in High street) was the most eligible they could discover. It answered perfectly with a telescope which magnified 100 times, and a microscope of about thrice that power.

Sir John Herschel then conceived the stupendous fabric of his present telescope. The power of his father's would still leave him distant from his favorite planet forty miles; and he resolved to attempt a greater magnifier. Money, the wings of science as the sinews of war, seemed the only requisite, and even the acquisition of this, which is often more difficult than the task of Sisypheus, he determined to achieve. Fully sanctioned by the high optical authority of Sir David Brewster, he laid his plan before the Royal Society, and particularly directed to it the attention of the President, His Royal Highness the Duke of Sussex, the ever munificent patron of science and the arts.—It was immediately and enthusiastically approved by the committee chosen to investigate it, and the chairman, who was the Royal President, subscribed his name for a contribution of \$10,000, with a promise that he would zealously submit the proposed instrument as a fit object for the patronage of the privy purse. He did so without delay, and his Majesty on being informed that the estimated expense was \$70,000, naively enquired if the costly instrument would conduce to any improvement in navigation? On being informed that it undoubtedly would, the sailor King promised a *carte blanche* for the amount which might be requisite.

Sir John Herschel had submitted his plans and calculations in adaption to an object glass of twenty-four feet in diameter: just six times the size of his venerable father's. For casting this ponderous mass, he selected the large glass-house of Messrs. Hartly and Grant (the brother of our invaluable friend Dr. Grant) at Dumbarton. The material chosen, was an amalgamation of two parts of the best crown with one of flint glass, the use of which, in separate lenses, constituted the great achromatic discovery of Dolland. It has been found, however, by accurate experiments, that the amalgam would as completely triumph over every impediment, both from infrangibility and discoloration, as the separate lenses. Five furnaces of the metal, carefully collected from productions of the manufactory of both the kinds of glass, and known to be respectively of nearly perfectly homogeneous quality, were united, by one grand conductor, to the mould; and on the 3d of January, 1833, the first cast was effected. After cooling eight days, the mould was opened and the glass found to be greatly flawed within eighteen inches of the centre. Notwithstanding this failure a new glass was more carefully cast on the 27th of the same month, which on being opened during the first week in February, was found to be immaculately perfect, with the exception of two slight flaws so near the line of its circumference that they would be covered by the copper ring in which it was designed to be enclosed.

The weight of this prodigious lens was, 14,896 lbs. or nearly seven tons after being polished; and its estimated magnifying power 24,000 times. It was therefore presumed to be capable of representing objects in our lunar satellite of but little more than eighteen inches in diameter, provided its focal image of them would be rendered distinct by the transference of artificial light. It was not, however, upon the mere illuminating power of the hydro-oxygen microscope, as applied to the focal pictures of this lens, that the younger Herschel depended for the realization of his ambitious theories and hopes. He calculated largely upon the most illimitable applicability of this instrument as a second magnifier which would supersede the use, and infinitely transcend the powers of the highest magnifiers in reflecting telescopes.

So sanguinely, indeed, did he calculate upon the advantages of this splendid alliance, that he expressed confidence in his ultimate ability to study even the entomology of the moon, in case also

contained insects upon the surface. Having witnessed the completion of his great lens, and its safe transportation to the metropolis, his next care was the construction of a suitable microscope, and of the mechanical frame work for the horizontal and vertical action of the whole. His plans in every branch of his undertaking having been intensely studied, even to their minutest details, were easily and rapidly executed. He awaited only the appointed period at which he was to convey his magnificent apparatus to its destination.

A correspondence had for some time passed between the Boards of Longitude of England, France and Austria, with a view to improvements in the tables of longitude in the southern hemisphere; which are found to be much less accurate than those of the northern. The high opinion entertained by the British Board of Longitude of the principles of the telescope, and of the profound skill of its inventor, determined the government to solicit his services in observing the transit of Mercury over the sun's disk, which will take place on the 7th of November in the present year; and which, as it will occur at 7h. 47m. 55s. night, conjunction, mean time; and at 8h. 12m. 22s. middle, true time, will be invisible to nearly all the northern hemisphere. The place at which the transits, both of Mercury and of Venus have generally been observed by the astronomers of Europe, when occurring under these circumstances, is the Cape of Good Hope; and no transit of Venus having occurred since the year 1769, and none being to occur before 1874, the accurate observation of the transits of Mercury, which occur more frequently, has been found of great importance both to astronomy and navigation. To the latter useful art, indeed, the transits of Mercury are nearly as important as those of Venus; for although those of the latter planet have the peculiar advantage of determining exactly the great solar parallax, and thence the distances of all the planets from the sun, yet the transits of Mercury, by exactly determining the place of its own node, independently of the parallax of the great orb, determine the parallax of the earth and moon, and are therefore especially valuable in lunar observations of longitude. The Cape of Good Hope has been found preferable, in these observations, to any other station in the hemisphere.—The expedition which went to Peru, about the middle of the last century, to ascertain, in conjunction with another in Lapland, the true figure of the earth, found the attraction of the mountainous regions so strong as to cause the plumb-line of one of their large instruments to deflect seven or eight seconds from the true perpendicular; whilst the elevated plains at the cape unite all the advantages of a lucid atmosphere with an entire freedom from mountainous obstruction.—Sir John Herschel, therefore not only accepted the appointment with high satisfaction, but requested that it might commence at least a year before the period of the transit, to afford him time to bring his ponderous and complicated machinery into perfect adjustment, and to extend his knowledge of the southern constellations.

His wish was immediately assented to, and his arrangements being completed, he sailed from London on the 4th of September, 1834, in company with Dr. Andrew Grant, Lieut. Drummond, of the Royal Engineers, F. R. A. S. and a large party of the best English mechanics. They arrived after an expeditious and agreeable passage, and immediately proceeded to transport the lens, and the frame of the large observatory, to its destined site, which was a piece of table land of great extent and elevation, about thirty-five miles north-east of the Cape town; and which is said to be the very spot on which De la Caille, in 1750 constructed his invaluable solar tables, when he measured a degree of the meridian, and made a great advance to exactitude in computing the solar parallax, from that of Mars and the Moon. Sir John accomplished the ascent by means of two relief teams of oxen, of eighteen each, in about four days; and, aided by several companies of Dutch boers, proceeded at once to the erection of his gigantic fabric.

The ground plan of the structure, is in some respects similar to that of the Herschel telescope in England, except that instead of circular foundations of brickwork, it consists of a series of parallel circles of railroad iron, upon wooden frame work; so constructed that the turn-outs, or rather turn-ins, from the largest circle, will conduct

the observatory, which moves upon them, to the innermost circle, which is the basis of the lens works; and to each of the circles that intervene. The diameter of the smallest circle is 23 feet; that of the largest our correspondent has singularly forgotten to state, though it may be in some measure computed from the angle of incidence projected by the lens, and the space occupied by the observatory. The latter is a wooden building fifty feet square and as many high, with a flat roof and gutters of thin copper. Through the said proximate to the lens, is an aperture four feet in diameter to receive its rays, and through the roof another for the same purpose in meridional observations. The lens, which is enclosed in a square frame of wood, and braced to its corners by bars of copper, is suspended upon an axis between two pillars which are nearly as high as those which supported the celebrated quadrant of Uleg Beg, being one hundred and fifty feet. These are united at the top and bottom by cross pieces, and strengthened by a number of diagonal braces; and between them is a double capstan for hoisting the lens from its horizontal line with the observatory to the height required by its focal distance when turned to the meridian; and for elevating it to any intermediate degree of altitude that may be needed. This last operation is beautifully regulated by an immense double sextant, which is connected and moves with the axis of the lens, and is regularly divided into degrees, minutes, and seconds; and the horizontal circles of the observatory, being also divided into 360 degrees and minutely subdivided, the whole instrument has the powers and regularity of the most improved theodolite. Having no tube, it is connected with the observatory by two horizontal levers, which pass underneath the floor of that building from the circular basis of the pillars; thus keeping the lens always square with the observatory, and securing to both a uniform and simple movement. By means of these levers, too, and a rack and windlass, the observatory is brought to any degree of approximation to the pillars that the altitude of an observation may require; and although, when at the nearest station it cannot command an observation with the great lens with in about fifteen degrees of the meridian, it is supplied with an excellent telescope of vast power, constructed by the elder Herschel, by which every high degree can be surveyed. The field of view, therefore, whether exhibited on the floor or on the wall of the apartment, has a diameter of nearly fifty feet, and, being circular, it has therefore an area of nearly 1865 feet. The place of all the horizontal movements having been accurately levelled by Lieut. Drummond, with the improved level of his invention which bears his name, and the wheels both of the observatory and of the lens-works being facilitated by friction rollers in patent axle boxes filled with oil, the strength of one man applied to the extremity of the levers, is sufficient to propel the whole structure upon either of the rail road circles; and that of two men applied to the windlass, is fully adequate to bring the observatory to the basis of the pillars. Both of these movements, however, are now effected by a locomotive apparatus, commanded within the apartment by a single person, and showing, by means of an ingenious index, every inch of progression or retrogression.

We have not thus particularly described the telescope of the younger Herschel, because we consider it the most magnificent specimens of philosophical mechanism of the present or any previous age, but because we deemed an explicit description of its principles and powers an almost indispensable introduction to a statement of the sublime expansion of human knowledge which it has achieved. It was not fully completed until the latter part of December, when the series of large reflectors for the microscope arrived from England; and it was brought into operation during the first week of the ensuing month and year.—But the secrecy which had been maintained with regard to its novelty, its manufacture, and its destination, was not less rigidly preserved for several months, respecting the grandeur of its success. Whether the British Government were sceptical concerning the promised splendor of its discoveries, or wished them to be scrupulously veiled until they had accumulated a full-orbed glory for the nation and reign in which they originated, is a question which we can only conjecturally solve. But certain it is that the astronomer's royal patrons enjoined a masquerade taciturnity upon him and his friends, until he should have officially communicated the results of his great

experiment. Accordingly, the world heard nothing of him or his expedition, until it was announced a few months since, in the scientific journals of Germany, that Sir John Herschel, at the Cape of Good Hope, had written to the Astronomer Royal of Vienna, to inform him that the portentous comet predicted for the year 1835, which was to approach so near this trembling globe that we might hear the roaring of its fires, had turned upon another scent, and would not even shake a hair of its tail over our hunting-grounds. At a loss to conceive by what extra authority he had made so bold a declaration, the men of science in Europe who were not acquainted with his secret, regarded his "postponement," as his discovery was termed, with incredulous contempt; and continued to terrorize upon the strength of former predictions.

#### NEW LUNAR DISCOVERIES.

Until the 10th of January, the observations were chiefly directed to the stars in the southern signs, in which, without the aid of the hydro-oxygen reflectors, a countless number of new stars and nebulae were discovered. But we shall defer our correspondent's account of these to future pages, for the purpose of no longer withholding from our readers the more general and highly interesting discoveries which were made in the lunar world.—And for this purpose, too, we shall defer Dr. Grant's elaborate mathematical details of the corrections which Sir John Herschel has made in the best tables of the moon's tropical, sidereal, and synodic revolutions; and of those phenomena of the syzygies on which a great part of the established lunar theory depends.

It was about half past nine o'clock on the night of the 10th, the moon having then advanced within four days of her mean libration, that the astronomer adjusted his instruments for the inspection of her eastern limb. The whole immense power of his telescope was applied, and to its focal image about one half of his microscope. On removing the screen of the latter, the field of view was covered throughout its entire area, with a beautifully distinct and even vivid representation of *basaltic rock*. Its color was a greenish brown, and the width of the columns, as defined by their interstices on the canvas, was invariably twenty-eight inches. No fracture whatever appeared in the mass first presented, but in a few seconds a shelving pile appeared of five or six columns width, which showed their figure to be hexagonal, and their articulations similar to those of the basaltic formation at Staffa. This precipitous shelf was profusely covered with a dark red flower, "precisely similar," says Dr. Grant, to the Papaver Rhaean, or rose-poppay of our sublimity cornfields; and this was the first organic production of nature in a foreign world, ever revealed to the eyes of men."

The rapidity of the moon's ascension, or rather of the earth's diurnal rotation, being nearly equal to five hundred yards in a second, would have effectually prevented the inspection or even the discovery of objects so minute as these, but for the admirable mechanism which constantly regulates, under the guidance of the sextant, the required altitude of the lens. But its operation was found to be so consummately perfect, that the observers could detain the object upon the field of view for any period they might desire. The specimen of lunar vegetation, however, which they had already seen, had decided a question of too exciting an interest to induce them to retard its exit. It had demonstrated that the moon has an atmosphere constituted similarly to our own, and capable of sustaining organized, and therefore, most probably, animal life. The Basaltic rocks continued to pass over the inclined canvas plane, through three successive diameters, when a verdant declivity, of great beauty, appeared, which occupied two more. This was preceded by another mass of nearly the former height: at the base of which they were at length delighted to perceive that novelty, a lunar forest. "The trees," says Dr. Grant, "for a period of ten minutes, were of one unvaried kind, and unlike any I have seen, except the largest class of yews in the English church yards, which they in some respects resemble. These were followed by a level green plain, which, as measured by the painted circle on our canvas, of forty-nine feet, must have been more than half a mile in breadth; and then appeared as fine a forest of firs, unequivocal firs, as I have ever seen cherished in the bosom of my native mountains.

Wearied with the long continuance of these, we gradually reduced the magnifying power of the

microscope, without eclipsing either of the reflectors, and immediately perceived that we had been insensibly descending, as it were, a mountainous district of highly diversified and romantic character, and that we were on the verge of a lake, or inland sea; but of what relative locality or extent, we were yet too greatly magnified to determine. On introducing the feeblest achromatic lens we possessed, we found that the water whose boundary we had just discovered, answered in general outline to the Mare Nubium of Riccioli, by which we detected that instead of commencing, as we supposed, on the eastern longitude of the planet, some delay in the elevation of the greater lens, had thrown us nearly upon the axes of her equator. However, as she was a free country, and we not as yet attached to any particular province, and, moreover, since we could at any moment, occupy our intended position, we again slid in our magic lenses to survey the shores of the Mare Nubium. Why Riccioli so termed it, unless in ridicule of Cleomenes, I know not; for fairer shores never angel coasted on a tour of pleasure. A beach of brilliant white sand, girt with wild castellated rocks, apparently of green marble, and varied at chasms, occurring every two or three hundred feet, with grotesque blocks of chalk or gypsum, and feathered and festooned at the summits with the clustering foliage of unknown trees, moved along the bright wall of our apartment until we were speechless with admiration. The water, wherever we obtained a view of it, was nearly as blue as that of the deep ocean, and broke in large white billows upon the strand. The action of very high tides was quite manifest upon the face of the cliffs, for more than a hundred miles; yet, diversified as the scenery was during this and a much greater distance, we perceived no trace of animal existence, notwithstanding we could command at will a perspective of a foreground view of the whole. Mr. Holmes, indeed, pronounced some white objects of a circular form, which he saw at some distance in the interior of a cavern, to be bona fide specimens of large cornu ammonis; but to me they appeared merely large pebbles, which had been chafed and rolled there by the tides. Our chase of animal life was not yet to be rewarded.

Having continued this close inspection nearly two hours, during which we passed over a wide tract of country, chiefly of a rugged, and apparently volcanic character; and having few additional varieties of vegetation, except some species of lichen, which grew every where in great abundance, Dr. Herschel proposed that we should take out all our lenses, give a rapid speed to the panorama, and search for some of the principal valleys known to astronomers, as the most likely method to reward our first night's observation with the discovery of animated beings. The lenses being removed, and the effulgence of our unutterably glorious reflectors left undiminished, we found, in accordance with our calculations, that our field of view comprehended about twenty five miles of the lunar surface, with the distinctness both of outline and detail which could be procured of a terrestrial object of the distance of two and a half miles: an optical phenomenon which you will find demonstrated in Note 5.—This afforded us the best landscape views we had hitherto obtained, and although the accelerated motion was rather too great, we enjoyed them with rapture. Several of these famous valleys which are bounded by lofty hills of so perfectly conical a form as to render them less like works of nature than of art, passed the canvass before we had time to check their flight; but presently a train of scenery met our eye, of features so entirely novel, that Dr. Herschel signalled for the lowest convenient gradation of movement. It was a lofty chain of obelisk shaped, or very slender pyramids, standing in irregular groups, each composed of about thirty or forty spires, every one of which was perfectly square, and as accurately truncated as the finest specimens of Cornish crystal. They were of a faint lilac hue, and very resplendent. I now thought that we had assuredly fallen on productions of art; but Dr. Herschel shrewdly remarked that if the Lunarians could build thirty or forty miles of such monuments as these, we should ere now have discovered others of a less equivocal character. He pronounced them quartz formations, of probably the wine colored amethyst species, and promised us, from these and other proofs which we had obtained of the powerful action of the laws of crystallization in this planet, a rich field of mineralogical study.

On introducing a lens, his conjecture was fully confirmed; they were monstrous amethysts of a diluted claret color, glowing in the intensest light of the sun! They varied in height from sixty to ninety feet, though we saw several of a still more incredible altitude.

They were observed in a succession of valleys divided by longitudinal lines of round breasted hills, covered with verdure and nobly undulated; but, what is most remarkable, the valleys which contained these stupendous crystals were invariably barren, and covered with stones of a ferruginous hue, which were probably iron pyrites. We found that these curiosities were situated in a district elevated about half a mile above the valley of the Mare Fecunditatis, of Mayor and Riccioli; the shores of which soon hove in view. But never was a name more inappropriately bestowed.—From "Dan to Bersheba" all was barren,—the sea-board was entirely composed of chalk and flint, and not a vestige of vegetation could be discovered with our strongest glasses. The whole breadth of the northern extremity of this sea, which was about three hundred miles, having crossed our plane, we entered upon a wild mountainous region abounding with more extensive forests of larger trees than we had before seen—the species of which I have no good analogy to describe.—In general contour they resembled our forest oak; but they were much more superb in foliage, having broad glossy leaves like those of the laurel, and tresses of yellow flowers which hung, in the open glades, from the branches to the ground. These mountains passed, we arrived at a region which filled us with astonishment. It was an oval valley, surrounded, except at a narrow opening towards the south, by hills, red as the purest vermillion, and evidently crystallized; for wherever a precipitous chasm appeared—and these chasms were very frequent, and of immense depth,—the perpendicular sections presented conglomerated masses of polygon crystals evenly fitted to each other, and arranged in deep strata, which grew darker in color as they descended to the foundations of the precipices. Innumerable cascades were bursting forth from the breasts of every one of those cliffs, and some so near their summits, and with such great force, as to form arches many yards in diameter. I never was so vividly reminded of Byron's simile, "the tail of the white horse in the Revelations." At the foot of this boundary of hills was a perfect zone of woods surrounding the whole valley, which was about eighteen or twenty miles wide, at its greatest breadth, and about thirty in length. Small collections of trees of every imaginable kind, were scattered about the whole luxuriant area; and here our magnifiers blessed our panting hopes with specimens of conscious existence. In the shade of the woods on the south eastern side, we beheld continuous herds of brown quadrupeds, having all the external characteristics of the bison, but more diminutive than any species of the bes genus in our natural history. Its tail was like that of our bos grunniens; but in its semicircular horns, the hump on its shoulders, the depth of its dew-lap, and the length of its shaggy hair, it closely resembled the species to which I first compared it. It had, however, one widely distinctive feature, which, we afterwards found common to nearly every lunar quadruped we have discovered; namely, a remarkable fleshy appendage over the eyes, crossing the whole breadth of the forehead and united to the ears. We could most distinctly perceive this hairy veil, which was shaped like the upper front outline of the cap known to the ladies as Mary Queen of Scots cap, lifted and lowered by means of the ears. It immediately occurred to the acute mind of Dr. Herschel, that this was a providential contrivance to protect the eyes of the animal from the great extremes of light and darkness to which all the inhabitants of our side of the moon are periodically subjected.

The next animal perceived would be classed on earth as a monster. It was of a blueish lead color, about the size of a goat, with a head and beard like him, and a single horn, slightly inclined forward, from the perpendicular. The female was destitute of the horn and beard, but had a much longer tail.—It was gregarious, and chiefly abounded on the acclivitous glades of the woods. In elegance of symmetry, it rivalled the antelope, and like him it seemed an agile sprightly creature, running with great speed, and springing from the green turf with all the unaccountable antics of a lamb or

kitten. This beautiful creature afforded us the most exquisite amusement. The mimicry of its movements upon our white painted canvass, was as faithful and luminous as that of animals within a few yards of a camera obscura when seen pictured upon its tympan. Frequently when attempting to put our fingers upon its beard, it would suddenly bound away into oblivion, as if conscious of our earthly impertinence; but then others would appear, whom we could not prevent from nibbling the herbage, say or do what we would to them.

On examining the centre of this delightful valley, we found a large branching river, abounding with lovely islands, and water-birds of numerous kinds.—A species of grey pelican was the most numerous; but a black and white crane with unreasonably long legs and bill, were also very common. We watched their piscivorous experiments a long time, in hopes, of catching sight of a lunar fish; but although we were not favored in this respect, we could easily guess the purpose for which they plunged their long necks so deeply beneath the water. Near the upper extremity of one of these islands, we obtained a glimpse of a strange amphibious creature of a spherical form, which rolled with great velocity across the pebbly beach, and was lost sight of in the strong current which set off from this angle of the island. We were compelled, however, to leave this prolific valley unexplored on account of clouds which were evidently accumulating in the lunar atmosphere, our own being perfectly translucent. But this was itself an interesting discovery, for more distant observers had questioned or denied the existence of any humid atmosphere in this planet.

The moon being now low on her descent, Dr. Herschel inferred that the increasing refrangibility of her rays would prevent any satisfactory protraction of our labors, and our minds being actually fatigued with the excitement of the high enjoyments we had partaken, we mutually agreed to call in the assistants at the lens, and reward their vigilant attention with congratulatory bumpers of the best "East India Particular." It was not, however, without regret that we left the splendid valley of the red mountains, which, in compliment to the arms of our royal patron, we denominated "the Valley of the Unicorn;" and it may be found in Blunt's map, about midway between the Mare Fœcunditatis, and the Mare Nectaris."

The nights of the 11th and 12th being cloudy were unfavorable to observation; but on those of the 13th and 14th further animal discoveries were made of the most exciting interest to every human being. We give them in the graphic language of our accomplished correspondent:—

"The astonishing and beautiful discoveries which we had made during our first night's observation, and the brilliant promise which they gave of the future, rendered every moonlight hour too precious to reconcile us to the deprivation occasioned by these two cloudy evenings; and they were not borne with strictly philosophical patience, notwithstanding our attention was closely occupied in superintending the erection of additional props and braces of the twenty-four feet lens, which we found had somewhat vibrated in a high wind that arose on the morning of the 11th. The night of the 13th [January] was one of pearly purity and loveliness. The moon ascended the firmament in gorgeous splendor, and the stars, retiring around her, left her the unrivalled queen of the hemisphere. This being the last night but one in the present month, during which we should have an opportunity of inspecting her western limb, on account of the libration in longitude which would thence immediately ensue, Dr. Herschel informed us that he should direct our researches to the parts No. 2, 11, 26, and 30, in Blunt's map, and which are respectively known in the modern catalogue by the names of Endymion, Cleomedes, Longrenus, and Petavius. To the careful inspection of these, and the regions between them and the extreme western rim, he proposed to devote the whole of this highly favored night. Taking then our twenty-five miles breadth of her surface upon the field view, and reducing it to a slow movement, we soon found the first very singularly shaped object of our inquiry. It was a highly mountainous district, the loftier chains of which form three narrow ovals, two of which approach each other in slender points, and are united by one mass of hills of great length and elevation; thus presenting a figure similar to that of a long skein of thread, the bows of which have been gradually spread open from their connecting knot. The third oval looks also like

a skein, and lies as if carelessly dropped from nature's hand in connection with the other; but that which might fancifully be supposed as having formed the second bow of this second skein, is cut open, and lies in scattered threads of smaller hills which covers a great extent of level territory. The ground plan of these mountains is so remarkable that it has been drawn; and in Blunt's, which is the best, it agrees exactly with my description. Within the grasp, as it were, of the broken bow of hills last mentioned, stands an oval shaped mountain enclosing a valley of immense area, and having, on its western ridge, a volcano in a state of terrible eruption. To the northeast of this, across the broken, or what Mr. Holmes called "the vagabond mountain," are three other detached oblong formations, the largest and last of which is marked F in the catalogue, and fancifully denominated the Mare Mortuum, or more commonly the "Lake of Death." Induced by a curiosity to divine the reason of so sombre a title, rather than by any more philosophical motive, we here first applied our hydro-oxygen magnifiers to the focal image of the great lens. Our 25 miles portion of this great mountain circus, had comprehended the whole of its area, and of course the two conical hills which rise within it about five miles from each other; but although this breadth of view had heretofore generally presented its objects as if seen within a terrestrial distance of two and a half miles, we were, in this instance, unable to discern these eternal hills with any such degree of distinctness. There did not appear to be any mist or smoke around them, as in the case of the volcano which we had left in the southwest, and yet they were comparatively indistinct upon the canvass. On sliding in the gas-light lens, the mystery was immediately solved. They were old craters of extinct volcanoes, from which still issued a heated though transparent exhalation that kept them in an apparently oscillatory or trembling motion, most unfavorable to examination. The craters of both of these hills, as nearly as we could judge under this obstruction, were about 15 fathom deep, devoid of any appearance of fire, and of nearly a yellowish white color throughout. The diameter of each was about nine diameters of our painted circle, or nearly 450 feet; and the width of the rim surrounding them about 1000 feet; yet, notwithstanding their narrow mouths, these two chimneys of the subterranean deep had evidently filled the whole area of the valley in which they stood with the lava and ashes with which it was encumbered, and even added to the height, if not indeed caused the existence of the oval chain of mountains which surrounded it. These mountains, as subsequently measured from the level of some large lakes around them, averaged the height of 2800 feet, and Dr. Herschel conjectured from this and the vast extent of their abutments, which ran for many miles into the country around them, that these volcanoes must have been in full activity for a million of years. Lieut. Drummond, however, rather supposed that the whole area of this oval valley was but the exhausted crater of one vast volcano, which in expiring had left only these two imbecile representatives of its power. I believe Dr. Herschel himself afterwards adopted this probable theory, which is indeed confirmed by the universal geology of the planet. There is scarcely a hundred miles of her surface, not even excepting her large seas and lakes, in which circular or oval mountainous ridges may not be easily found; and many, very many of these having numerous inclosed hills in full volcanic operation, which are much lower than the surrounding circles, admit of no doubt that each of these great formations are the remains of one vast mountain which has burnt itself out, and left only these wide foundations of its ancient grandeur. A direct proof of this is afforded of a tremendous volcano now in its prime, which I shall afterwards notice. What gave the name of "The Lake of Death" to the annular mountain I have just described, was, I suppose, the dark appearance of the valley which it encloses, and which to a more distant view than we obtained, certainly exhibits the general aspect of the waters on this planet. The surrounding country is fertile to excess; between this circle and No. 2 (Endymion) which we proposed first to examine, we counted no less than twelve luxuriant forests, divided into open plains, which waded in an ocean of verdure, and were probably prairies like those of North America. In three of these we discovered numerous herds of quadrupeds similar to our friends the bison in the Valley of the Unicorn, but of much larger size; and scarcely

a piece of woodland occurred in our panorama which did not dazzle our vision with flocks of white or red birds upon the wing.

"At length we carefully explored the Endymion. We found each of the three ovals volcanic and sterile within; but without, most rich, throughout the level regions around them, in every imaginable production of a bounteous soil. Dr. Herschel has classified not less than thirty-eight species of forest trees and nearly twice this number of plants, found in this tract alone, which are widely different to those found in more equatorial latitudes. Of animals, he classified nine species of mammalia, and five of oviparia. Among the former is a small kind of reindeer, the elk, the moose, the horned bear, and the biped beaver. The last resembles the beaver of the earth in every other respect than in its destitution of a tail, and its invariable habit of walking upon only two feet. It carries its young in its arms like a human being, and moves with an easy gliding motion. Its huts are constructed better and higher than those of many tribes of human savages, and from the appearance of smoke in nearly all of them, there is no doubt of its being acquainted with the use of fire.—Still his head and body differ only in the points stated from that of the beaver, and it was never seen except on the borders of lakes and rivers, in which it has been observed to immerse for a period of several seconds.

"Thirty degrees farther south, is No. 11, or Cleomedes, an immense annular mountain, containing three distinct craters, which have been so long extinguished that the whole valley around them, which is eleven miles in extent, is densely crowded with woods nearly to the summits of the hills. Not a rod of vacant land, except the tops of these craters, could be described, and no living creature except a large white bird resembling the stork. At the southern extremity of this valley is a natural archway or cavern, 200 feet high, and 100 wide, through which runs a river that discharges itself over a precipice of grey rocks 80 feet in depth and then forms a branching stream through a beautiful champagne district for many miles. Within twenty miles of this cataract is the largest lake, or rather inland sea, that has been found throughout the seven and a half millions of square miles which this illuminated side of the moon contains. Its width from east to west, is 189 miles, and from north to south, 266 miles. Its shape to the northward is not unlike that of the bay of Bengal, and it is studded with small islands, most of which are volcanic. Two of these, on the eastern side, are now violently eruptive; but our lowest magnifying power was too great to examine them with convenience, on account of the cloud of smoke and ashes which beclouded our field of view; as seen by Lieut. Drummond, through our reflecting telescope of 2000 times, they exhibited great brilliancy. In a bay, on the western side of this sea, is an island 55 miles long, of a crescent form, crowded through its entire sweep with the most superb and wonderful natural beauties, both of vegetation and geology. Its hills are pinnacled with tall quartz crystals, of so rich a yellow and orange hue that we at first supposed them to be pointed flames of fire; and they spring up thus from smooth round brows of hills which are covered as with a velvet mantle. Even in the enchanting little valleys of this winding island, we could often see those splendid natural spires, mounting in the midst of deep green woods, like church steeples in the vale of Westmoreland. We here first noticed the bar palm tree, which differs from that of our tropical latitudes only in the peculiarity of very large crimson flowers, instead of the spadix protruded from the common calx. We, however, perceived no fruit on any specimens we saw; a circumstance which we attempted to account for from the great (theoretical) extremes in the lunar climate. On a curious kind of tree-melon we nevertheless saw fruit in great abundance, and in every stage of inception and maturity. The general color of these woods was a dark green, though not without occasional admixtures of every tint of our forest seasons. The hectic flush of autumn was often seen kindled upon the cheek of earliest spring, and the gay drapery of summer, in some places, surrounded trees leafless as the victims of winter. It seemed as if all the seasons here united hands in a circle of perpetual harmony. Of animals, we saw only an elegant striped quadruped, about three feet high, like a miniature Zebra, which was always in small herds on the green sward of the hills; and two or three kinds of long tailed birds which we judged to be golden and blue pheasants. On the shores,

however, we saw countless multitudes of univalve shell fish, and among them some huge flat ones which all three of my associates declared to be *cornu ammonis*; and I confess I was here compelled to abandon my skeptical substitution of pebbles.—The cliffs all along these shores were deeply undermined by tides; they were very cavernous, and yellow crystal stalactites larger than a man's thigh were shooting forth on all sides. Indeed every foot of this island appeared to be crystalized; masses of fallen crystals were found on every beach we explored, and beamed from every fractured head land. It was more like a creation of an oriental fancy, than a distant variety of nature brought by the powers of science to ocular demonstration. The striking dissimilitude of this island to every other we had found on these waters, and its near proximity to the main land, led us to suppose that it must some time have been a part of it; more especially as its crescent bay embraced the first of a chain of smaller ones which ran directly thither. This first one was a pure quartz rock, about three miles in circumference, towering in naked majesty from the blue deep without either shore or shelter. But it glowed in the sun almost like a sapphire, as did all the lesser ones of whom it seemed the king. Our theory was speedily confirmed; for all the shore of the main land was battlemented and spired with those unobtainable jewels of nature, and as we brought our field of view to include the utmost rim of the illuminated boundary of the planet, we could still see them blazing in crowded battalions as it were, through a region of hundreds of miles. In fact, we could not conjecture where this gorgeous land of enchantment terminated; for as the rotary motion of the planet bore these mountain summits from our view, we became further remote from the western boundary.

"We were admonished by this to lose no time in seeking the next proposed object of our search, the *Langrenus*, or No. 26, which is almost within the verge of the libration in longitude, and of which, for this reason, Dr. Herschel entertained some singular reasons.

"After a short delay in advancing the observatory upon the levers, and in regulating the lens, we found our object and surveyed it. It was a dark narrow lake seventy miles long, bounded on the east, north and west, by red mountains of the same character as those surrounding the valley of the Unicorn, from which it is distant to the south west about 160 miles. This lake, like that valley, opens to the south upon a plain not more than ten miles wide, which is here encircled by a truly magnificent amphitheatre of the loftiest order of lunar hills. For a semi-circle of six miles these hills are risen, from their brow to their base, as perpendicularly as the outer walls of the Colosseum at Rome; but here exhibiting the sublime altitude of at least two thousand feet, in one smooth unbroken surface. How nature disposed of the huge mass which she thus prodigally carried out, I know not; but certain it is that there are no fragments of it left upon the plain, which is a declivity without a single prominence except a billowy tract of woodland that runs in many a wild vagary of breadth and course to the margin of the lake. The tremendous height and expansion of this perpendicular mountain, with its bright crimson front contrasted with the fringe of forest on its brow, and the verdure of the open plain beneath, filled our canvass with a landscape unsurpassed in unique grandeur by any we had beheld. Our 25 miles perspective included this remarkable mountain, the plain, a part of the lake, and the last graduated summits of the range of hills by which the latter is nearly surrounded.—We ardently wish that all the world could view a scene so strangely grand, and our pulse beat high with the hope of one day exhibiting it to our countrymen in some part of our native land.—But we were at length compelled to destroy our picture, as a whole, for the purpose of magnifying its parts for scientific inspection. Our plane was of course immediately covered with the ruby front of this mighty amphitheatre, its tall figures, leading cascades, and rugged caverns. As its almost intermediate sweep was measured off upon canvass, we frequently saw long lines of some yellow metal, hanging from the crevices of the horizontal strata in wide net work, or straight pendant branches. We of course concluded that this was virgin gold, and we had no assay-master to prove the contrary. On searching the plain, over which we had observed the woods roving in all the shapes of clouds in the sky, we were again delighted with

the discovery of animals. The first observed was a quadruped with an amazingly long neck, head like a sheep, bearing two long spiral horns, white as polished ivory, and standing in perpendicular parallel to each other. Its body was like that of a deer, but its fore legs were most disproportionately long, and its tail, which was very bushy and of a snow whiteness, curled high over its rump, and hung two or three feet by its side. Its colors were bright bay and white, in brindle patches, clearly defined but of no regular form. It was found only in pairs, in spaces between the woods, and we had no opportunity of witnessing its speed or its habits. But a few minutes only elapsed before three specimens of another animal appeared, so well known to all that we fairly laughed at the recognition of so familiar an acquaintance in so distant a land. They were neither more nor less than three good large sheep, which would not have disgraced the farms of Leicestershire, or the shambles of Leadenhall market. With the utmost scrutiny we could find no mark of distinction between these and those of our native soil; they had not even the appendage over the eyes, which I have described as common to lunar quadrupeds. Presently they appeared in great numbers, and on reducing the lenses, we found them in flocks over a great part of the valley. I need not say how desirous we were of finding shepherds to these flocks, and even a man with blue apron and rolled up sleeves, would have been a welcome sight to us, if not to the sheep; but they fed in peace, lords of their own pastures, without either protector or destroyer in human shape.

"We at length approached the level opening to the lake, where the valley narrows to a mile in width, and displays scenery on both sides, picturesque and romantic beyond the powers of a prose description, imagination borne on the wings of poetry, could alone gather similes to portray the wild sublimity of this landscape, where dark behemoth crags stood over the brows of lofty precipices, as if in ramparts in the sky; and forests seem suspended mid air. On the eastern side there was one soaring crag, crested with trees, which hung over in a curve like three-fourths of a gothic arch, and being of a rich crimson color, its effect was most strange upon minds unaccustomed to the association of such grandeur with such beauty. But whilst gazing upon them in a perspective of about half a mile, we were thrilled with astonishment to perceive four successive flocks of large winged creatures, wholly unlike any kind of birds, descend with a slow even motion from the cliffs on the western side, and alight upon the plain. They were first noticed by Dr. Herschel, who exclaimed, "Now, gentlemen, my theories against your proofs, which you have often found a pretty even bet, we have something worth looking at; I was confident that if ever we found beings in human shape, it would be in this longitude, and that they would be provided by their Creator with some extraordinary powers of locomotion: first exchange for my number D." This lens being soon introduced, gave us a fine half mile distance; and we counted three parties of these creatures, of twelve, nine and fifteen in each, walking erect towards a small wood near the base of the eastern precipices. Certainly they were like human beings for their wings had now disappeared, and their attitude in walking was both erect and dignified. Having observed them at this distance for some minutes we introduced lens H. z. which brought them to the apparent proximity of eighty yards; the highest clear magnitude we possessed until the latter end of March, when we effected an improvement in the gas-burners. About half of the first party had passed beyond our canvass; but of all the others we had a perfectly distinct and deliberate view. They averaged four feet in height, were covered, except on the face, with short and glossy copper-colored hair, and had wings composed of a thin membrane, without hair, lying snugly upon their backs, from the top of the shoulders to the calves of the legs.—The face, which was of a yellowish flesh color, was a slight improvement upon that of the large orang outang, being more open and intelligent in its expression, and having a much greater expansion of forehead. The mouth, however, was very prominent, though somewhat relieved by a thick beard upon the lower jaw, and by lips far more human than those of any species of the simia genus. In general symmetry of body and limbs they were infinitely superior to the orang outang; so much so, that, but for their long wings, Lieutenant Drummond said that they would look as well on a

parade ground as some of the old cockney militia! The hair on the head was a darker color than that of the body, closely curled, but apparently not woolly, and arranged in two curious semi-circles over the temple of the forehead. Their feet could only be seen as they were alternately lifted in walking; but, from what we could see of them in so transient a view, they appeared thin, and very protuberant at the heel.

"Whilst passing across the canvass, and whenever we afterwards saw them, these creatures were evidently engaged in conversation; their gesticulation, more particularly the varied action of their hands and arms, appeared impassioned and emphatic. We hence inferred that they were rational beings, and although not perhaps of so high an order as others which we discovered the next month on the shores of the Bay of Rainbows, they were capable of producing works of art and contrivance. The next view we obtained of them was still more favorable. It was on the borders of a little lake, or expanded stream, which we then for the first time perceived running down the valley to the large lake, and having on its eastern margin a small wood. Some of these creatures had crossed the water and were lying like spread eagles on the skirts of the wood. We could then perceive that their wings possessed great expansion, and were similar in structure to those of the bat, being a semi-transparent membrane, expanded in curvilinear divisions by means of straight radii, united at the back by the dorsal integuments. But what astonished us very much was the circumstance of this membrane being continued from the shoulders to the legs, united all the way down, though gradually decreasing in width. The wings seemed completely under the command of volition, for those of the creatures whom we saw bathing in the water, spread them instantly to their full width, waved them as ducks do theirs to shake off the water, and then as instantly closed them again in a compact form. Our further observation of the habits of these creatures, who were of both sexes, led to results so very remarkable, that I prefer they should be first laid before the public in Dr. Herschel's own work, where I have reason to know they are fully and faithfully stated, however incredulously they may be received. \* \* \*

The three families then almost simultaneously spread their wings and were lost in the dark confines of the canvass, before we had time to breathe from our paralyzing astonishment. We scientifically denominated them the *Vespertilio-homo*, or man-bat; and they are doubtless innocent and happy creatures, notwithstanding some of their amusements would but ill comport with our terrestrial notions of decorum.—The valley itself we call the Ruby Coliseum, in compliment to its stupendous boundary, the six mile sweep of red precipices two thousand feet high. And the night, or rather morning, being far advanced, we postponed our tour to Petavious (No. 20) until another opportunity."

We have of course faithfully observed Dr. Grant's private injunction to omit those highly curious passages in his correspondence, which he wished us to suppress, although we do not clearly perceive the force of the reasons assigned for it. It is true the omitted paragraphs contain facts which would be wholly incredible to readers who do not carefully examine the principles and capacity of the instrument with which these marvellous discoveries have been made; but so will also nearly all of those which he has kindly permitted us to publish; and it was for this reason that we considered the explicit description which we have given of the telescope so important a preliminary. From these, however, & other prohibited passages which will be published by Dr. Herschel, with the certificates of the civil and military authorities of the colony, and of several Episcopal, Wesleyan, and other ministers, who, in the month of March last, were permitted, under the stipulation of temporary secrecy, to visit the observatory and become eye witnesses of the wonders which they were requested to attest, we are confident his forthcoming volumes will be at once the most sublime in science, and the most intense in general interest, that ever issued from the press.

The night of the 14th displayed the moon in her mean libration; or full; but the somewhat humid state of the atmosphere being for several hours less favorable to a minute inspection than to a general survey of her surface, they were chiefly devoted to the latter purpose. But shortly after midnight the last veil of mist was dissipated, and the sky being as lucid as on the former evenings, the attention of the astronomers was arrested by the remarkable

outlines of the spot marked Gycho, No. 18; in Blunt's lunar chart; and in this train they added treasures to human knowledge which angels might well desire to win.

# SUMMARY.

LETTERS have been received from an officer on board the Delaware, dated off Malta, 26th June, 1835—officers and crew all well. The Delaware was going immediately to Tripoli.

It is understood that the Delaware will sail for the U. States as soon as the Constitution reaches Port Mahon.

DON THOMAS GENER.—It is with deep feelings of regret we learn that this eminent individual died at Matanzas, about the 16th August. The immediate cause of this deplorable and unexpected event, was the overturning of a carriage—by which he received some mortal hurt.

We know few individuals in any country, whose loss should be more truly looked upon, as one to all lovers of freedom, to all good men. A man of head, of heart, and of hand, Don Thomas Gener lacked but an appropriate sphere, to make himself felt as one fitted to decide the destinies of nations. With the high acquirements and high qualities of a Statesman, he combined much simplicity of character—and all the gentler social virtues. As a philanthropist, a friend, a husband, and a father—his memory will endure, while the grateful hearts, which in all those relations he gladdened, shall continue to beat.

To Cuba—of which glorious island no one better understood than he, the vast resources, and possible futurity—great indeed, is the cause of mourning—at this untimely death.

AN Act to prohibit the circulation of small Bills, passed March 31, 1835.

The People of the State of New York, represented in Senate and Assembly, do enact as follows:

SECTION 1. It shall not be lawful for any person or corporation to pay, give, or offer in payment, or in any way circulate or attempt to circulate, as money, at any time after the first day of September next, within this State, any bill, note, or other evidence of debt, purporting to be issued by any body corporate, of a denomination less than two dollars: and it shall not be lawful for any person or corporation to pay, give, or offer in payment, or in any way circulate or attempt to circulate, as aforesaid, at any time after the first day of September, One Thousand Eight Hundred and Thirty Six, any such bill, note or other evidence of debt of a denomination less than Five Dollars, or of a denomination between Five Dollars and Ten Dollars.

§ 2. Any person offending against any of the provisions of the foregoing section, shall forfeit for every offence five times the nominal value of any such bill, note or other evidence of debt, to be recovered with costs of suit in the name and for the use of any person who shall sue for the same, and prosecute such suit to judgment in any court having cognizance thereof.

§ 3. It shall not be lawful for any corporation having banking powers in this State, at any time after thirty days from the passage of this Act, to issue or in any manner put in circulation, any note, bill or other evidence of debt, of any denomination less than Two Dollars; and it shall not be lawful for any such corporation, at any time after the first day of September next, to issue or in any manner put in circulation, any such bills, notes or other evidences of debt of any denomination less than Three Dollars; and it shall not be lawful for any such corporation, at any time after the first day of March, One thousand Eight hundred and Thirty-six, to issue or in any manner put in circulation, any such bills, notes or other evidences of debt, of a denomination less than Five Dollars; nor shall it be lawful for any such corporation at any time hereafter, to issue, or in any manner put in circu-

lation, any such bills, notes or other evidences of debt of a denomination between Five and Ten Dollars.

§ 4. Any such corporation violating the provisions of the foregoing section shall forfeit one hundred dollars for each bill issued or put in circulation contrary thereto, to be recovered in the name and for the use of any person who may sue therefor; the court of chancery may by injunction, restrain such corporation and its officers from exercising any of its corporate rights, privileges or franchises, and from collecting or receiving any debts or demands and from paying out, or in any way transferring or delivering to any person any of the moneys, property, or effects of such corporation, until such court shall further order.

§ 5. Any person who shall purchase or take at a discount, any bill, note or other evidence of debt, purporting to be issued by any banking corporation or body corporate, not chartered by the laws of this State, and the circulation of which is prohibited by this act, shall, in addition to the forfeiture provided by the second section of this act, also forfeit for every such offence, the sum of fifty dollars to be recovered with costs, in the manner provided by said second section; and any incorporated company in this State, that shall, by its officers, agents or servants, take or receive in the course of its business any such bill, note or other evidence of debt, purporting to be issued by any corporation not chartered by the laws of this State, shall, on conviction thereof, forfeit its charter.

§ 6. So much of the act, entitled "An act to prohibit the circulation of bills of banks not chartered by the laws of this State, under the denomination of five dollars," passed April 30, 1830, as is inconsistent with this act, is hereby repealed.

§ 7. The fifth and sixth sections of this act shall take effect on the first day of September next.

While we feel it our duty to notify all, whom this paper may reach, of the actual law on this subject, (which in brief is that all notes under five dollars, of foreign banks, and all notes under two dollars, of New York banks, are now prohibited,) we must add the expression of our belief, that this law, like that against small notes from other States, which has for the last five years been on our statute books—will in effect be—a dead letter. Neither the public sentiment, nor the public convenience, sanction the law, and against them, no such law can be executed.

PACKET SHIP SHEFFIELD.—The passengers by the Sheffield have presented Captain F. P. Allen a very elegant silver pitcher (made in Marquand's best style), in testimony of their sense of his liberality, gentlemanly attention, and nautical skill, during her late passage from Liverpool to this port.

The editor of the Transcript has discovered, by reference to the town records of Boston, that Geo. R. T. Hewes, "the man of a hundred years, who visited us last July," and was tosted every where as "the last of the tea-party," was born on the 25th of August, 1742—from which it seems that the old gentleman has been adding seven years to his age—he being in fact only ninety-three.—[Ib.]

Mr. J. Orville Taylor is on his return from a tour throughout the state, having been lecturing in the different counties on the deficiencies of common schools. We are gratified to learn from him, that he has succeeded in awakening a very lively interest in the behalf of our district schools, and has received from gentlemen in every part of the State a hearty co-operation, and the warmest welcome.—[Oneida Whig.]

SENECA FALLS.—The population of Seneca Falls village is 2,525; of which 1,296 are males, and 1,231 females. In 1825 that village contained only 265, and 1610 in 1831. Hydraulic operations and business generally have kept pace with the population.

PERILOUS BALLOON ASCENSION.—We learn from the Lynchburg Virginian, that Mr. Hobart returned to that place on Tuesday last, after a most perilous flight through the upper regions. The balloon was cut from the cord at seven o'clock, and in less than an hour he landed near Walker's church, in Prince Edward county—distant about 38 miles! We, says the paper, regret that Mr. Hobart has not yet been able to prepare a description of his dangerous journey. We must, there-

fore, content ourselves for the present with stating a few of the prominent particulars.

In a very few minutes after the balloon left the earth it was lost to view by passing into a cloud. Mr. Hobart informs us, that, after that time, he lost sight of the earth entirely. At half past seven he took his last observation, when he was upwards of three miles from the earth. About that period he saw two brilliant meteors, one in the north, and the other in the west—the latter seeming to approach him, but disappearing without coming in contact, very much to Mr. H's relief, who feared the ignition of the gas. Shortly after, he encountered a severe gale, the balloon and car being whirled to an immense height, he supposes not less than 26,000 feet from the earth, from the effects produced upon his respiration and sense of hearing—finding it extremely difficult to breathe, and being entirely unable to hear. He attempted to operate on the safety-valve, but from his inability to hear, could not ascertain whether the gas escaped or not. In this situation he every moment feared the balloon would burst, and that some of his husband vessels would be ruptured. He soon found, from the elevation of the lower part of the balloon, that his apprehensions were in part realized. He began to descend with great velocity, and fortunately landed on a favorable spot, his fall being broken by a pine sappling, on which he alighted. He was hurled from the car, however, with considerable force, and was severely jarred by the fall, breaking his valuable barometer, and damaging some of his other instruments. Had he descended in the woods, by which he was nearly surrounded, he thinks his death would have been inevitable; and he evidently had a very narrow escape. On examining the balloon, it was found to have sustained a rent, near the top, of about twenty inches in length, and several parts in which it had previously broken and patched had all been re-opened. It is now completely ruined.

MICHIGAN.—An extra meeting of the Legislative Council, convened by the proclamation of the Governor, commenced at Detroit, on the 18th of August. The Governor sent to them a long message, recapitulating the whole history of the border controversy, and finally submitting for their decision, the compromise recommended by the Commissioners of the U. S., Messrs. Rush and Howard.

LATER FROM ENGLAND.—By the ship Trenton, at Boston, London papers to 25th July are received, one day later than before. They announce the close of the Irish church question, in the House of Commons, and the loss of the amendment, or rather division of the question, proposed by Sir Robert Peel, and so ably enforced in the speech we published last week—by a majority of 37. The vote was for the motion of Sir R. Peel 262, against 319.

Lord Stanley spoke in favor of the amendment, and Mr. Ward, Mr. Sheil, Mr. O'Connell, Lord Morpeth, and Lord John Russell against it. Lord John Russell stated in reply to a question put to him, that he should on the part of the Ministers, bring in a bill on the subject of tithes in England, at the next session.

It was asserted, on the authority of letters from Germany, that the Northern governments were preparing to acknowledge Don Carlos as King of Spain, and that Count Alarida, the agent of the latter at Vienna, had almost daily intercourse with Prince Metternich to settle the terms. It was supposed that the defeat of Don Carlos in his attempt to get possession of Bilbao, would operate unfavorably for his interests abroad.

LATER FROM FRANCE.—The packet ship Natchez, Captain White, arrived last night from Havre, bringing papers of that port and Paris to the 24th, inclusive.

The Toulon Journals of the 17th inst. state that the Cholera had been evidently on the decline there for several days, but they had received accounts of its having increased at Grasse and Frejus, and had also broken out on board the hulks at Nice, in consequence of which, the convicts had been sent to Villefranche. At Toulon, from being abandoned by their colleagues, three of the Municipal Counsellors have died from fatigue.

From the French papers, we learn that the want of money is severely felt in the Carlist army.—The last supplies of cattle by the French purveyors have not been paid for, and the troops are still

in want of provisions. The inhabitants of Navarre are again under apprehensions of seeing their country traversed by the armies. The large cattle which constitutes their wealth have almost wholly disappeared.

General Mina arrived at Toulon from Montpellier on the 17th ult., his wound being completely healed.

Letters from Vienna and Berlin announce in positive terms, the approaching acknowledgment of Don Carlos by the Northern Powers. This acknowledgment will, it said, counterbalance the quasi-intervention of France and England.

Letters from Algiers of the 12th ult., confirm the intelligence from that place and Oran, respecting the serious check experienced by the French. A more detailed account is given of the encounter but presents nothing further of consequence.

[From the Courier and Enquirer.]

#### TEXAS.

VELASCO.—Mouth of the Brazos River, August 3d, 1835.

The Mexican Government appears determined to extend the benefits of the political change about being made in the government of the Republic, to the Colony of Texas, or in other words, to establish here a despotic Military Government. But the occupation of the principal ports, and the stations of the Colony by the Mexican troops, presents great difficulties. The troops are all concentrated at San Antonio De Bexar, not a soldier having yet appeared at San Felipe, Brazoria, or Galveston Bay. The settlers are not opposed to the establishment of Custom Houses, but they appear determined to resist Military Government, especially in the department of Nacogdoches—situated on the frontier of the United States, where an efficient militia was formed, more than sufficient to resist any attack on that side, which, however, is not in the least apprehended, owing to the great distance from San Antonio de Bexar. The communications between Nacogdoches and the U. States, were perfectly free, and the arrivals from the western States were more considerable than last year. In some departments of the interior of the Colony, the militia is under organization, whilst in others the people remain quiet, watching the movements of the Mexican troops. Should these invade San Felipe and Brazoria, the whole country will soon be in arms; a provisional government will then be established at Nacogdoches, and the independence of the Colony, or its union with the United States at once declared.

A Mexican Government Schooner has been cruising for some days past on the coast, and is at present at the mouth of the river Brazos.

Senor Zavala arrived here a few days back, and was well received by the settlers.

Colonel Austin is daily expected from New Orleans, but being now considered a supporter of the administration of Santa Anna, he has lost his former popularity in the Colony. For my part I think this accusation against the persecuted Colonel, unfounded, and I confidently hope it will turn out so.

The Colony continues healthy, and the crops very good.

Mexico.—We have received, via New Orleans, Mexican papers to the 28th July. The general Congress of the Union met again at the City of Mexico, on the 19th of the same month, with the customary ceremonies, on which occasion the Vice President Barragan, in a speech to the Representatives, exhorted them to take into consideration the present state of affairs, to ascertain closely the wishes of the people as regards the reforms in the constitution, and the establishment of a system of government calculated to put an end to the evils of civil war, and to secure permanent order and tranquillity to the country. The Count of Tagle, President of the House of Representatives, replied to the Vice President in a long speech, in which we find the usual professions of patriotism, and personal pledges by the House, to promote the liberty, peace, and welfare of the Mexicans, &c. No motion of importance had yet been made in either House.

The country remained quiet. The ship Montezuma was to leave Vera Cruz the 1st instant.

#### RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order car wheels, chairs and knees, and every other description of castings required for railroads. R-ly 16b14

#### PARTNER WANTED.

Wanted, a partner in an extensive Printing Establishment. No one need apply who is not a thoroughbred printer, competent to superintend and direct an office in which upwards of 30 persons are employed, and able to furnish \$3000 cash capital. The best of references will be given and required. Letters, with real name, may be addressed to P. P. P., Post Office, New-York, postage paid, and they will be promptly attended to. May-17

#### TO CONTRACTORS FOR EXCAVATION AND MASONRY.

PROPOSALS will be received at the Office of the Philadelphia and Reading Rail Road Company, in Philadelphia, on the 19th and 20th days of October next, for the Grading and Masonry, of about sixteen miles of the Rail Road between Pottsgrove and Norristown.

In this distance, a large amount of heavy work, deserving the attention of skillful and competent Contractors, is to let. The Jobs of most magnitude, are a Tunnel 600 yards long, and a Bridge across the Schuylkill, near Phoenixville.

Plans and profiles of the line, and drawings of the different constructions on it will be exhibited, and all other information in relation to it will be afforded, on application at the Engineer's Office, at Pottsgrove, for ten days previous to the letting. MONCURE ROBINSON, C. E. Philadelphia, Sept. 2, 1835. a2 Saw1019

#### TO TUNNEL MINERS, DRILLERS, &c.

Wanted, immediately, 40 Tunnel Miners, (Cornish Miners will be preferred,) 80 Drillers, 50 Laborers, and two experienced Mine Blacksmiths, on the New-York and Harlem Railroad, about five miles from the City. Liberal wages will be given, and cash payments made every fortnight. Apply at Mr. FOWLER'S, St. John's Hall, Frankfort street, New-York.

JOHN RUTTER, Contractor.

The Albany Argus, Philadelphia U. S. Gazette and Pennsylvania, will please copy this, and send their bills to the Railroad Company, 14 Wall street, New-York. 23-17

#### NOTICE TO CONTRACTORS

Sealed Proposals will be received at the Hudson and Berkshire Railroad Company's Office, in the city of Hudson, until the 31st day of September next, for excavating and embanking 14 miles of their Road from Arnold's shop, near Groat's, at Chatham Four Corners, to the state line, and also for constructing 8 Bridges, from 60 to 70 feet each, between the abutments. Plans of the masonry and superstructure of the bridges will be exhibited at the Railroad Office. Contractors will be required to furnish all the materials for bridges; and the masonry to be completed by the 1st of December next. The road to be graded for a double track, 24 feet wide. A part of the road will be heavy rock and gravel excavation. Profiles of this part of the route will be exhibited at the Railroad Office, in Hudson, and also at the Office of the Engineer, at Chatham Four Corners. The road will be divided into sections of one half and one mile each in length, and prepared for examination by the 10th of August.

Proposals will also be received for furnishing 500,000 feet, B. M., of White Oak Rails, 6 by 7 inches square, and 16 feet long. Also, 15,000 Oak or Chestnut Ties, 6 by 7 inches square, 8 feet long, or, if round, not less than 8 inches in diameter, at small end. Also, 500,000 feet of Chestnut, Pine, or Hemlock Sills, 4 by 10 inches, 12, 16, or 20 feet long.

The whole to be subject to the inspection of the Engineer, and to be delivered on the line of the road, by the 15th of April, 1836.

The remaining 18 miles of the route will be put under contract as soon as the line can be prepared.

Persons applying for contracts will be expected, unless personally known to the Engineer, to present with their proposals recommendations as to ability to perform their contracts.

Any information on the subject afforded at the Engineer's Office, Chatham Four Corners.

JAMES MELLE, President.

GEORGE RICH, Chief Engineer.

Hudson, Aug. 1, 1835. 31-5t

#### AMES' CELEBRATED SHOVELS, SPADES, &c.

500 dozens Ames' back-strap and plain Shovels,  
75 do do round-pointed do  
150 do do cast steel Shovels and Spades,  
100 do do Socket Shovels and Spades,  
150 do do steel plated Spades.  
Together with Pick Axes, Churn Drills, and Crow Bars, steel pointed, made from Salisbury refined Iron. For sale by his Agents,

WITHERELL, AMES & CO.

2 Liberty street, New-York.

BACKUS, AMES & CO.

8 State street, Albany.

#### RAILROAD IRON WORK,

Of all kinds, made to order by GODWIN, CLARK & CO., Paterson, New-Jersey.

CAR WHEELS, BOXES, AXLES, and CAR SPRINGS, made and fitted complete, at short notice, and fair prices.

Orders addressed to them at Paterson, N. J., or 24 Broad street, N. Y., will meet with immediate attention. Paterson, Aug. 19, 1835. 34-1y

#### STEPHENSON,

Builder of a superior style of Passenger Cars for Railroads,

No. 264 Elizabethstreet, near Bleecker street, New-York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. 3961f

#### RAILROAD CAR WHEELS AND BOXES AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS.

Also, Flange Tires turned complete.

J8 ROGERS, KETCHUM & GROSVENOR

#### PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

Railroad Spikes of every description required, made at the Albany Spike Factory.

Spikes made at the above Factory are recommended to the public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to admit water.

Orders may be addressed to Messrs. ERASTUS CORNING & CO., Albany, or to THOMAS TURNER, at the Factory, Troy, N. Y. sept.12-ly

#### RAILWAY IRON.

95 tons of 1 inch by 1/2 inch, Flat Bars in lengths of 200 do. 1 1/2 do. 14 to 15 feet, counter sunk  
40 do. 1 1/2 do. 14 do. holes, ends cut at an angle  
800 do. 2 do. of 45 degrees, with splicing plates and nails to suit.  
soon expected.

260 do. of Edge Rails of 36 lbs. per yard, with the requisite chairs, keys and pins.

Wrought Iron Rims of 30, 33, and 36 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels.

Axles of 24, 28, 32, 34, 36, and 38 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment. A. & G. BALSTON.

9 South Front street, Philadelphia.

Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them. 47imeowr

#### SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by

E. & G. W. BLUNT, 154 Water street, corner of Maiden lane. J31 6t

#### SURVEYING AND ENGINEERING INSTRUMENTS.

The subscriber manufactures all kinds of Instruments in his profession, warranted equal, if not superior, in principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new: among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Goniometer, with two Telescopes—and a Leveling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes.

WM. J. YOUNG,

Mathematical Instrument Maker,

No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested. Baltimore, 1832.

In reply to thy inquiries respecting the instruments manufactured by thee, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish thee the following information. The whole number of Levels now in possession of the department of construction of thy make is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accidents to which all instruments of the kind are liable.

I have found that thy patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a revolving telescope, in place of the vane sights, leaves the engineer scarcely any thing to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,

JAMES F. STABLE, Sup't of Construction

of Baltimore and Ohio Railroad.

Philadelphia, February, 1833.

Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Germantown, February, 1833.

For a year past I have used Instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these Instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

HENRY R. CAMPBELL, Eng. Philad.

Germant. and Norrist. Railroad

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, SEPTEMBER 12, 1836.

**NEW-YORK AND ERIE RAILROAD.**—We hail with heart-felt satisfaction the approaching commencement of this noble work. It will be seen by the following notice, that the Company are prepared to put under contract FORTY MILES of the road; and we are assured by the Engineer that as much more will be ready for contract this fall. Thus it will be seen that the Company turn neither to the right nor to the left, but with a degree of firmness characteristic of the gentlemen who have embarked in the enterprise, they go *a-head*; and the result of their independence, firmness and perseverance, will be, to overcome sectional and local opposition, and to convince all, who have sense and honesty enough to be convinced of any thing, that their aim is to promote the general, and their country's, prosperity.

### NEW-YORK AND ERIE RAILROAD.

**TO CONTRACTORS.**—Proposals will be received at the Office of this Company, No. 12 Wallstreet, in the City of New York, until the 5th of November next, for the grading of forty miles of the Railroad, along the Delaware River, and extending from the mouth of the Callikoon Creek (about sixty miles west of Newburgh) to the village of Deposit, in the County of Delaware. This portion of the work is now staked out in convenient sections, generally averaging one mile in length. Plans and profiles of the line, and printed forms of the contracts, (in which stipulations will be inserted prohibiting the use of ardent spirits) will be ready for exhibition on, and after the 30th of September instant, at the Office of the Division Engineer of the Eastern Division of the New York and Erie Railroad, in the village of Deposit. The Company reserve the privilege of accepting only such proposals as they may deem for their advantage.

JAMES G. KING, President.

New York, Sept. 6th, 1836.

We give in this number an account, with engravings, of Daglish's Prize Rail—and it is to be hoped that some of our numerous Railroad Companies will test its value.

We owe an apology to our punctual correspondent at Avoylle Ferry for the apparent delay of his report for June, but it was received only a few days previous to that for July. We hope, therefore, that he will not discontinue his much esteemed favors—and it would be highly gratifying if he would give a brief description of the country in which he resides, and also of the adjoining territory of Texas, especially in the vicinity of *Nacogdoches*.

We have more than once been desired, by our readers, to ask P. G. V. for this information, which we now take the liberty of doing.

**ELIZABETHTOWN AND SOMERVILLE, N. J., RAILROAD.**—We have been favored with a Report of the Committee of the Board, in relation to the above named railroad, and its continuation to Belvidere; where it is to cross the Delaware and unite with the *Susquehanna and Delaware* Railroad, to Pittston, on the *Susquehanna*; and from thence to the New-York line, to connect probably with the New-York and Erie Railroad, either at Binghamton, or Tioga Point, or both,—as may be hereafter deemed expedient.

From the following abstract of the Report, it appears that the route is altogether feasible and highly eligible—that it passes through a section of country in New-Jersey rich, not only in agricultural productions, but also in minerals and manufacturing privileges—that it will open a direct and easy communication both with the *anthracite* and *bituminous* coal regions of Pennsylvania, and at the same time divert to this city much of the trade which now descends the *Susquehanna* to Baltimore, and the Delaware, to Philadelphia.

Our attention has been before attracted

to this route, and we have frequently referred to it, as one of great importance to the city of New-York—and the more we reflect upon it, the more important it appears to us.

We shall give the Report entire in our next.

The route proposed is from Elizabethtown in New Jersey to Somerville, thence to Clinton, thence to Phillipsburg, opposite Easton, thence to Baltimore, thence crossing the Delaware to the Water Gap, thence to Pittston on the *Susquehanna*, and thence by such routes as will be deemed most advantageous to join the N. York and Erie Railroad.

Acts of incorporation exist for these respective routes granted by Pennsylvania and New Jersey.

From Elizabethtown to Somerville, the curves for a railroad are few and of large radii—the maximum slope only 5 feet in a mile—distance 23 miles—short branches may be made from this to Rahway, Bridgetown, New Brunswick and Perth Amboy.

The route from Somerville to Clinton, 31 miles, of easy grade, 7 feet slope per mile.

From Clinton to Belvidere, 73 miles, easy descent by water courses.

But the most important part of this report is that which touches ourselves at New York. It is affirmed that at Pittston, a choice is presented to unite with the New York and Erie Rail Road at Binghamton, by the Leggett's Gap Rail Road, or at Shepherd's corner, near Tioga point, by the *Susquehanna* Rail Road, for both of which Pennsylvania has granted liberal charters. The distance then to Portland on Lake Erie, by the New York and Erie Rail Route is, it is said, 516 miles; making by this route only 439 miles from New York, or seventy miles nearer than by any other practical route. If the route from Pittston by the *Susquehanna* Rail Road to the New York line is adopted—it passes within nine miles of the bituminous coal regions of Bradford and Tioga counties, and the course of the Lycoming, which runs to the W. branch of the *Susquehanna* and the Towanda, which empties into the N. branch and interlock at their summit, opening an easy route with the Elmira and Williamsport Rail Road. Thus the bituminous coal of Bradford, and Tioga counties, and the anthracite of the valley of Lackawannock, reach New York and the Northern and Eastern portions of New Jersey—one hundred miles nearer by this than by any other route. It is estimated that 200,000 tons of bread stuffs, lumber, &c. annually descend the *Susquehanna*, from within 20 miles of the N. York line. Two millions of merchandise are annually consumed by the counties in that neighborhood. The forests abound in curled maple and other choice timber. The land is rich—the water power abundant. The trade of the tributaries of the *Susquehanna* will thus be thrown, also by a short route, upon Philadelphia. The Delaware Water Gap protects the whole route from all competition, giving it thus a natural monopoly.

[From the London Mechanics' Magazine.]

#### DAGLISH'S PRIZE RAILS AND PEDESTALS.

Dear Sir,—I herewith send you drawings of my parallel rail and joint and intermediate pedestals, with the mode of fastening them to the stone blocks or sleepers, and also of my method of keying the rails into their respective pedestal; for all which I obtained the premium lately offered by the London and Birmingham Railway Directors, with the exception of the mode of fastening the pedestals to the stone blocks, which the Committee of Reference are said to have thought inferior to the lewis-pin of Mr. Swinburn, to whom the Directors accordingly awarded a third of the premium. I have also added sketches of certain modifications of my rail and pedestals, which it might be advisable to adopt under particular circumstances, and in some peculiar localities.

Fig. 1 (No. 8 of the Competition) is an end-section of the parallel rail and joint-pedestal (the pedestal where two ends of different lengths of rail meet;) showing also the mode of keying the rail by cotter

bolts, (No. 3 of the Competition.) Fig. 2 is a plan of the above; and fig. 3 a side-section. The weight 50 lbs. per yard. The stone blocks are from 10 to 12 inches thick, and contain from 4 to 5 cubic feet; the cotter bolts are  $\frac{3}{4}$  inch round.

I have tried this form of rail against ten other forms of rail of the like weight per yard or thereabouts, not only by actually running heavy locomotive engines over them, but by means of the steelyard and lever, and have always found that it will carry more weight than any other with the least deflection. The simplicity of its construction, too, is greatly in favor of its being soundly made.

Fig. 4 is an end-section of the same kind of rail, with the intermediate pedestals; and fig. 5, a plan of the same.

The joint-pedestal is made of nearly twice the bearing of the intermediate ones, in order that the ends may be the more effectually secured.

The Secretaries of the London and Birmingham Railway state, in their letter to me announcing the award of the premium

in my favor, (with the exception aforesaid,) that the Committee of Reference did not consider that any one of the patterns or plans sent in fulfilled the conditions required by their advertisement, (that is to say, I presume, combined in one all the advantages sought for,) but that my form of rail and chair, (or pedestal,) and mode of fixing the rail to the chair, (according to the chair pattern, No. 3, and model, No. 8,) were the best as regards the two first conditions of the advertisement; while the method of fixing the chair to the stone block, shown in model No. 5, (Mr. Swinburn's,) was the best as regards the third condition; and that the Directors had, therefore, come to the unanimous resolution, that they should not be justified in giving the premium for any one individual pattern or plan, but that 70*l.* of it should be awarded to me, and 35*l.* to Mr. Swinburn.

On comparing, however, the statements in this letter with those in the pamphlet lately published by Mr. Barlow (one of the Committee of Reference,) containing an account of the experiments made by him

at Woolwich, and his Report thereon to the London and Birmingham Railway Directors, I must confess that I am quite at a loss to reconcile the two. For it appears from the latter, that Mr. Barlow not only made his experiments with my form of rail, which he pronounces to be by far the best, but recommends the mode which I proposed of fixing the pedestal to the stone block, and not Mr. Swinburn's.

Indeed, to all who are practically conversant with railways, it must seem as inexplicable as surprising, that the lewis-pin method should have been thought worthy of favorable mention at all, far less of being honored with a premium. Were such a mode of fastening adopted, (as it, most assuredly, never will,) it would not be long before the concussions from the passage of heavy locomotive engines, at great velocities, would infallibly split the stone to the depth of the lewis.

The mode of fastening practised by me, and approved of by Mr. Barlow, (though, strange to say, not treated with like favor by the Committee of Judges, of whom Mr. Barlow was one,) consists, as will be partly seen from inspection of the figures, in inserting plain cotter bolts through the stone, and countersinking the hole up from the bottom for the space of an inch and a half or two inches, so as to permit the point of the bolt to drop below the base of the pedestal. I first tried screw-bolts, but was obliged to abandon them in consequence of the nuts getting, through corrosion, so fast to the bolts as to twist the bolt-ends off before they would unscrew. Fifteen years' experience has now satisfied me that the plain cotter bolt is the only one that will answer.

Mr. Barlow speaks of this method of fastening as if it were the suggestion of Mr. Vignoles. But how he should have fallen into such a mistake, I cannot comprehend; for it was not only fully shown in the models I sent in to the London and Birmingham Railway Directors, but the advantages of it were particularly dwelt upon in the letter which accompanied them. To place this beyond all doubt, I will here repeat those passages of my letter which relate to this point:

"The pedestal for the joint I would particularly recommend to be fastened to the sleeper with cotter bolts; I would also prefer fastening all the intermediate ones in like manner, though they would answer to be well nailed in the usual way, but much better with cotter bolts, as you then derive the greatest effect from the parallel rail, by keeping every pedestal firmly down. If only nailed, this may prevent the intermediate pedestals becoming fulcrums, in which case the fibres of the upper surface of the rail are not called into tension in the same ratio with those on the under side of the rail, immediately between the pedestals, while the locomotive or any other heavy carriages are passing along the line."

Again:

"I prefer the mode of fastening the pedestals with cotter bolts as by far the most effectual for general use; if even they have to be fastened with smaller bolts, (say  $\frac{1}{2}$  inch diameter,) more especially when they can be thus secured at as cheap a rate as if fastened by nails. The holes for the small bolts can be drilled through the stone sleepers for less than the large holes necessary to receive the wooden plugs; and the small bolt and cotter will only cost a trifle more than the nail and wood plug, as both the bolts and cotters can be made by a machine for that purpose."

Mr. Vignoles, though he certainly did not

suggest the use of the cotter bolt, has done me the honor to cause it to be adopted in the construction of the Dublin and Kingstown Railway, instead of the nails or spikes commonly used.

Mr. Barlow makes some very forcible observations, (which, in noticing his pamphlet, you have judiciously transferred to your pages,) on the importance of exact fitting and fastening; but to show you that all practical men have not been so indifferent to these matters as Mr. Barlow imagines, and indeed somewhat broadly insinuates, I will, with your leave, make another short extract from my letter to the London and Birmingham Railway Directors, which has an immediate bearing upon this part of the subject:

"I am quite sure a velocity of from 50 to 60 miles per hour may be obtained upon a well-constructed railway, with greater safety than one of 20 miles, upon any of the present lines yet in operation; not only from their having too tight a rail and ill-constructed pedestal, but from the mode of fixing them, especially at the joints, which is the great cause of so much deflection and sudden action, both vertically and horizontally—so that it is not in the power of man to make a locomotive engine to stand the action they are subject to long together.

"I have frequently stated to Companies, that every public railway ought to be laid down as accurate and as firm as it is possible for hands to do them; and, when that is done, to put a steam engine upon them to plane the surface, the same as we do our slide-rails."

I must also use the freedom to observe that, correct as Mr. Barlow's views are, of the importance of executing all railways in the best possible style of workmanship, he shows, in nearly all that regards the details, great want of practical knowledge. Speaking of keying the rails to the pedestals, he says, that "if the rails and chairs must not be permanently fixed to each other by direct means, it ought not to be attempted by indirect means, viz. by cotter keys or wedges, for either these will hold the rail to the chair, or they will not; if they do hold fast, they produce all the mischief which permanent fixing would occasion; and if they draw, then they do no good, although they may still do mischief." Now, if the Professor ever had an opportunity of carefully watching for a summer's day the passing of heavy steam carriages and long trains of other heavy carriages over a railway, he would never have ventured such a statement. He would have witnessed, that it is scarcely in the power of man to fasten the rails permanently to the pedestals. Aware of the impracticability of doing so, I do not allow the D key proposed by me, (see fig. 1.) when used to key the rail to the joint-pedestal, to be driven with more than a single-hand hammer; and I also stop it at its place when driven, the key being here merely intended to act as a steadiment to the rail. For before a locomotive engine or heavy train has passed twice over the rails, the whole of the keys give or yield of necessity in such a manner as to allow the rails to expand or contract more than double what they really do, or are subject to, from the differences of temperature to which they are exposed. With respect, however, to the intermediate pedestals of the five-yard rails, the more soundly they are keyed to the rail the better, so as not to injure the pedestal by over-driving the key, as there is more latitude in the holes through the base of the pedestals where the bolts pass, than would compensate for treble the expansion and contrac-

tion the rails are subject to. Besides, each of the holes drilled through the stone blocks upon which the pedestals rest is drilled  $\frac{1}{4}$ th of an inch larger than the diameter of the bolts, and the pedestals can never be so hard cottered down to the surface of the stone but what they will give a little. All difficulties on this head I got completely over several years back, in both wrought and cast-iron railways, which have been laid under my direction. I could refer Mr. Barlow to several miles of railway which have been worked for years, and remain at present perfectly firm, without the least distortion, either vertically or horizontally.

Again: notwithstanding Mr. Barlow has actually proved by experiment that the parallel rail is superior to the parabolic, or fish-bellied rail, and has taken some pains to show the neutral axis, which has little or nothing to do with the best form of rail; yet he has forgotten to point out one of the most essential advantages which the parallel rail has over the parabolic rail, as I have frequently proved by the steelyard lever. I have found that by holding the ends of the rails firmly down, at the joint-pedestal especially, the parallel rail of fifty per yard will carry upwards of a ton more, with the same deflection, than they will do if the ends are allowed to rise, which they will of course do if the end-pedestals are merely nailed down in the bad and ineffectual manner hitherto usual, namely, by common rails or spikes. When the rails are kept firmly down by proper means, the intermediate pedestals become so many fulcrums, and the tension of the fibres of the upper parts of the rail is called into play, as will be readily understood from inspection of the following diagram, in which AA represent the points of tension, and BB the points of deflection.

I perceive further from Mr. Barlow's experiments, that he considers the best rail for strength ought to be from  $4\frac{1}{2}$  to  $4\frac{3}{4}$  inches deep, from the upper to the lower surface. I am quite confident, however, that it will be found that the best form of wrought iron rail ought not to exceed  $3\frac{3}{4}$  inches deep, or 4 inches at most; for by making the rail higher, not only will the pedestal be much weakened, but there will be no possibility of holding the pedestals firm on their base, by cotter bolts or any thing else, more particularly at the shunts and curvatures of the line of railway, and even the stone blocks will be continually shaken. It is well known in practice, that the lower any rail and pedestal can be kept, the less is the destruction in them, and the less the action on the foundation upon which the stone blocks are placed. It is also equally well known, that a sufficient wrought iron rail can be made of the depth I have stated, (namely  $3\frac{3}{4}$  or 4 inches,) to resist the action of a locomotive of 12 to 14 tons weight, at a speed of 40 or 50 miles per hour, (or even more if necessary,) if it is properly laid and adjusted.

I find that the different railway companies are now going to have their rails manufactured to weigh as much as 60 lbs. per single yard. The additional 10 lbs. per yard ought, in my humble judgment, to be employed partly to strengthen the lower edge, and make it to rest more firmly on its basis, and partly to increase the width of the upper surface; both in the manner shown in fig. 6, which is a sectional view of what I consider the best form of a rail of this weight.

My object in these modifications is to increase the adhesion of the locomotive engines, as well as to give a little more bearing on the peripheries of their wheels, in order to make them last longer.

I understand the Directors of the Birmingham and Liverpool Railway (the Grand Junction,) have recently given an order for one or two thousand tons of parallel rails, the upper and lower edges of which are both alike; and that they have been induced to give this form of rail a trial by certain persons in their employment, who lay claim to it as an invention of their own, and put it off (naturally enough) as superior to all others. Now, the fact is, that twelvemonths ago, I gave one of their engineers a set of drawings, of rails and pedestals, of a variety of forms, and this was one of them. And, in my letter to the Directors of the London and Birmingham Railway, before quoted from, I also expressly made mention of this form of rail, as one that might be employed, but pointed out, at the same time, certain objections to its use, which restrained me from proposing it for adoption. My words were these:

"I have hesitated with myself, whether or not to make a pattern with the upper and lower edges exactly alike, so as to be able to use either side, in case the former should prove a little unsound in any part, which has hitherto been frequently the case, especially at the ends, as I am fully aware that the more metallic material that can be brought to the lower side adds considerable strength to the rails; but as you seem disposed not to exceed 50 lbs. per single yard, a little would be lost in the depth and height of the rail. Allow me to assure you, that no public railway company will ever regret having sufficient strength in the rails at the beginning, and that they ought not, by any means, to confine themselves to a pound or two in the yard, in order to make the work as complete and substantial as possible at the commencement. But, as it is, after mature consideration, and taking every thing into question, I prefer the models I have furnished, (Nos. 8 and 3,) as the keys will be more effectual."

Fig. 8 is a section of the form of rail that I recommended, and would still recommend, for adoption, where it is desired to construct it, so that it may be inverted if necessary. It is what I call a "fancy rail," but ought to weigh at least 55 lbs. per yard.

Where a railway is intended for locomotive engines of only from eight to ten tons weight, a rail of the form represented in fig. 9, and weighing only 45 lbs. per yard, will be found to answer sufficiently well.

For America, where they have great difficulty in obtaining stone blocks, and are in the custom of fixing their rails on wooden sleepers of lengths varying from 30 to 50 feet, secured by cross sleepers, the best form of rail is that shown in fig. 7. I have been informed by American engineers that they can get plenty of a hard durable timber, very suitable for the purpose, for little more than the expense of cutting it down in the forests, and sending it to the saw mills to be cut into scantlings fit for immediate use; and that a railway bed of this description will last for nearly twenty years. Sometimes they lay their rails on cross sleepers only, dispensing with the side pieces. Several orders for rails of the form above referred to are now executing under my inspection for railway companies in America.

But to return to our own country: Mr. Barlow, I observe, says, "For the intermediate chairs, I think a slight modification of Mr. Stephenson's would best answer the purpose, that is, I would support the rail in

Fig. 8.

Fig. 9.

the chair simply by the ends of two plain-ended pins, so as to give it the requisite steadiness with as little friction as possible. Of course I would have these pins pointing horizontally, or upwards, instead of downwards, as they do in the chair in the question." The chair here alluded to is, I presume, that for which Mr. Stephenson, junior, some time ago took out a patent, instead of submitting it, as might have been expected, to the test of the open competition, which his employers, the London and Birmingham Railway Directors, thought best for the interests of the public. As I have not myself seen any drawing or description of this chair, I am not prepared to offer any decided opinion upon it; but if its excellence consists (as Mr. B.'s language seems to indicate,) in supporting the rail "simply by the ends of two plain-ended pins," it must be one of the most inefficient of all the contrivances ever designed for the purpose. Mr. B. might as well make use of two of his fingers, as two such "plain-ended pins;" for after a locomotive engine had passed once or twice over them, they would be (not crushed, perhaps,) but rendered of no manner of use whatever.

Mr. Barlow says in a note to the passage last quoted, "It may be worth consideration, whether if this mode of fixing were adopted, it would not be practicable and advantageous to introduce pieces of felt, or other substance, within the seat of the chair, which would greatly subdue the jars that take place between metal and metal."

A crowning instance this, of the little practical acquaintance Mr. Barlow has with the subject about which he has written so learnedly. I have said that he might as well make use of two of his fingers as two of Mr. Stephenson, Jun.'s pins (if Mr. Stephenson's they be); and so I now take leave to tell him that as far as any benefit is to be derived from the insertion of felt within the chair, he might as well insert a piece of his thumb-skin.

I will only, Mr. Editor, trespass further on your valuable space, to make another brief extract from my letter to the London and Birmingham Railway Directors, which

contains a suggestion for the further security of the rails, that seems to me not undeserving of general attention:

"I should also advise, that each joint-pedestal should be coupled with the opposite one by an extended round bar of three-fourths or seven-eighths diameter, with a washer welded on each end, so as to drop on the ends of the copper bolts in order to keep the railway in true gauge. This I have found of great service even on common railways."

Trusting to the interest and importance of the subject for a justification of the length to which this letter has extended,

I remain, dear Sir, yours, respectfully,

ROBERT DASLIGH.

Orrell Cottage, near Wigan, May 26, 1835.

(From the London Repository of Patent Inventions, &c.)

EXPERIMENTS ON THE PRESERVATION OF SHEET-IRON FROM RUST, IN INDIA. BY JAMES PRINSEP, Esq.—The proposed extensive employment of iron steam-boats, for the navigation of the Ganges, rendered it a desideratum to ascertain what varnish or composition would best preserve the exterior surface of such vessels from the rapid corrosion to which iron is so peculiarly subject in a hot climate. A series of experiments was undertaken with this view by myself, at the requisition of government; and it may perhaps be useful to record the principal results in a journal of science.

Two sets of six wrought-iron plates, each measuring 3 feet by 2 feet, were fixed to two iron triangles, the plates being prevented by studs from coming into contact with each other. The same varnishes were applied to both sets, one being intended for entire submersion under water, the other to be only half immersed, in order to [that it might] feel the united influence of air and water.

The following were the coatings applied:

1. Common coal-tar laid on hot, and the plate heated.
2. *Thetree* varnish of Ava, one coat. This took a very considerable time (two months) to dry, kept first in a cool room, and afterwards in a room heated by furnaces.\*
3. Native *Dhuna*, applied to the iron hot, in a thick uneven coat.
4. Best white-lead paint, three coats; allowed to dry and harden for nearly three months.
5. Coachmakers' varnish, two coats; dried rapidly.
6. Spirit varnish, several coats; warmed.
7. White wax, melted on the surface.
8. White wash, of pure lime water.
9. The surface of the iron plate cleaned and guarded with an edging of zinc, soldered on.
10. The natural surface of the rolled iron sheets, covered with its usual hardened grey oxide.

Many of the foregoing were employed from curiosity only, especially No. 6, the

\* Major Burney states, that three or four days are sufficient for the varnish to dry when laid on wood (Journal, vol. i. p. 172). I had not a damp vault in which to expose the plate as recommended by that officer, and that may partly account for the delay in drying; but all varnish and paint takes longer to dry on metal than on wood, from its non-absorbent nature.

spirit varnish, which had, on many occasions, proved quite ineffectual in preserving the surface of polished iron and steel from rust in the atmosphere of Calcutta.

The two frames were suspended as above described, one under water, the other half immersed, from one of the unused dredging boats, near the Chitpur lock gates, in the circular canal, where they were left undisturbed for three months, during a period of the year when the water of the canal was only slightly salt.

They were then taken up for examination, and presented the following appearances.

- | Plates under water.  | Plates half above water.  |
|--|---|
| 1. Tar—Perfectly preserved and free from rust.   | 1. Tar—A few dots of rust between wind and water.   |
| 2. Thetsee—Perfectly uninjured in appearance.  | 2. Thetsee—A line of rust at the level of the water.  |
| 3. Dhuna—White and pulverulent; soft and easily rubbed off while wet: rust here and there. | 3. Dhuna—Large cracks from the contraction of the part exposed to the sun, whitened where thick, black where thin; plate preserved above water. |
| 4. Paint—Almost wholly disappeared, and blotches of rust on the surface.                   | 4. Paint—Paint uninjured above water mark, and plate preserved, but below water entirely removed.   |
| 5. Copal varnish—Whitened, pulverulent, and soft; but not much oxidized.                   | 5. Copal varnish—In air less whitened, spots of rust breaking out every where.  |
| 6. Spirit varnish—Whitened and very rusty.   | 6. Spirit varnish—Very much corroded.   |
| 7. Wax—No trace of wax left, and very rusty.   | 7. Wax—This plate was all under water.  |
| 8. Lime—Flaky, peeled off, and very much corroded.   | 8. Lime—In air remains on and acts pretty well.   |
| 9. Zinc—The clean iron excessively corroded and bad: the zinc also oxidized.               | 9. Zinc—Much more rusty in the air than under water, where a kind of crust was formed.  |
| 10. None—The natural surface was a little whitened, and pretty well preserved.             | 10. None—Rusty on the edges, or where it had been scraped; elsewhere little injured.  |

The superior preservative power of coal-tar to all the substances tried, with the exception perhaps of the thetsee, was evident; the Burmese varnish labored under the disadvantage of being a single coat, otherwise it would, doubtless, from its hardness, its firm adherence, and its inalterability by water, prove fully equal as a lacquer to the coal-tar: the latter has, on the other hand, the advantage of drying and hardening as soon as laid on.

The change effected on the resinous varnishes is produced by an actual chemical combination with the water; the soft pulverulent matter is analogous to the white powder obtained by the addition of water to an alcoholic, or to an acid solution of resin.

The failure of the zinc guard, which was expected to act as an electro-positive protector to the iron, may, I think, be attributed to its being adulterated with lead, which being negative with respect to iron, would cause, as was actually the case, a more rapid oxidation of the latter metal: (the impurity of the zinc was afterwards fully proved.)

The wax and the white paint had entirely disappeared from the surface of the metal under water, before the plates were taken up; it is impossible, therefore, to say in what way their removal was effected.

The bituminous (coal-tar) coating was finally adopted, and it has been successfully applied to the iron steamer, the Lord William Bentinck, lately launched under Captain Johnston's superintendence.—[Journal of the Asiatic Society of Bengal.]

CHEMICAL EXAMINATION OF THE PETROLEUM OF RANGOON.—By ROBT. CHRISTISON, M. D., F. R. S. E., Professor of Materia Medica in the University of Edinburgh, &c.—At the close of the preceding session, the Council of the Society did me the honor of entrusting me with the chemical examination of several articles sent not long ago to the Society by Mr. Swinton, Secretary to the Government at Calcutta. The articles in question are, 1, Specimens of the *black varnish* used in different parts of Hindostan and the Burmese territories, with specimens of the juices of which these varnishes are said to be compounded. 2, Specimens of *naphtha* from Persia, and of *petroleum* from Rangoon. 3, Specimens of *wood-oil*, a variety of fluid turpentine. 4, Specimens of crude *caoutchouc*, and of solutions of it in wood-oil.

The only one of these articles which has hitherto yielded results of such interest as to induce me to lay them before the Society, is the petroleum of Rangoon, which appears to contain a compound inflammable principle hitherto unknown.

The petroleum of Rangoon, termed by Mr. Swinton earth-oil, and more generally in the East, ground-oil, is probably the same with what may be procured in various parts of our eastern dominions, by merely digging a few feet into the soil. In the vicinity of Rangoon it may be obtained in immense quantity for the mere trouble of digging it. It is used in Hindostan as pitch for all manner of wood-work; and is likewise a favorite external remedy for rheumatism, being employed for that purpose in the way of friction.

I am not aware that either this, or any of the European petroleum, has been subjected to careful analysis; and I should suppose no such analysis has been made, because no chemist, even with a careless examination, could have failed to observe that it contains a peculiar principle, the discovery of which would have given the analysis publicity.

The petroleum of Rangoon, at ordinary temperatures in this country, is a soft solid, of the consistence of lard. Its specific gravity, at the temperature of 60° Fahr., is 880, water being 1000. At the temperature of 86°, it is of the consistence of thin paste, and at 90° it melts completely, and forms a sluggish liquid, which acquires more fluidity as the temperature rises. Hence in the East, during the hot season, when it is dug for, it must be in the fluid state, and consequently entitled to its vulgar name of ground-oil. It has a powerful naphthous odor, different from that of most other petroleum.

It is impossible to analyze this petroleum by means of the ordinary chemical solvents. Most of these solvents, such as

the acids and alkalies, have little or no action on it, while alcohol, which acts feebly, and ether and the volatile oils, which act energetically, dissolve all its principles indiscriminately. The only practicable method of analysis, therefore, is the process by distillation.

When six ounces of petroleum were distilled, there was first procured, at a low heat, an ounce of nearly colorless naphtha; then another ounce of straw-yellow naphtha; then, at a higher heat, about another ounce, much more yellow, yet still fluid at 60° Fahr.; next, a considerable quantity of a yellowish liquid, which concreted at 60° into a loose mass, composed of numerous crystalline needles and plates, in a yellow naphthous fluid; and, as the distillation went on, this matter became more and more solid, but even towards the end was not firmer in consistence than lard. The residual matter in the retort, when the heat had been raised to full redness, was a spongy charcoal.

The naphtha, when rectified by a second distillation over a lamp, and then by a third distillation from the vapor-bath, is limpid and colorless, like sulphuric ether, and its density as 779. From the trials I have made, I consider that the Rangoon petroleum, when distilled on a large scale, will yield nearly a third of its volume of this colorless naphtha.

I need scarcely observe, that in eastern countries, where the fresh juice of the caoutchouc tree cannot be procured, the naphtha from the Rangoon petroleum may prove a useful article. Like other kinds of naphtha it freely dissolves, or rather softens, caoutchouc; which, after the evaporation of the solvent, is recovered with its original properties. When it is to be used for this purpose, however, it must be carefully separated by distillation from the crystalline matter I am presently to describe, which rises as the distillation advances, and gives the naphtha a yellow color. For if any material proportion of this impurity be present, the caoutchouc solution dries very slowly, and long retains a greasy surface.

The yellowish, concrete, crystalline matter, like the petroleum itself, is not acted on by the caustic alkalies, or by the strong acids. Alcohol dissolves it very sparingly; ether and the essential oils, freely and entirely. None of these solvents, therefore, is of any use for separating the crystalline matter from the mass. But I have succeeded in procuring it in a state of purity by the following process:

The mass being cooled down to about 40° Fahr. it was spread out on the filtering paper, and then subjected to strong pressure between many folds of common blotting paper. In this manner, an oily-like matter was taken up by the paper, and a pale yellowish white crystalline substance was left, which was subsequently deprived of its remaining color by repeated solution in boiling ether and re-crystallization. Ether dissolved it largely, forming a pale yellow solution, which, on being cooled by immersing the vessel in very cold water, became a soft mass of interwoven crystals. This mass was then

taken out, spread quickly on filtering paper, and immediately subjected to strong pressure between folds of blotting paper. The yellow coloring matter, which all remained in solution in the ether after it cooled, was thus, in a great measure, imbibed by the paper; and the crystalline matter was procured in a state of purity by repeating this process twice.

On first procuring this crystalline substance, I considered it as the same with the naphthaline procured not long ago from coal-tar by Mr. Kidd, as related in his paper in the Philosophical Transactions for 1821. This opinion I was led to form from the appearance of the crystals, the nature of the substance which yields them, and the process of distillation by which they were procured.

On a careful examination, however, I find that the crystalline principle of petroleum differs materially from that of coal-tar, as well as from every other known body; and I shall therefore beg leave to denominate it *Petroline*, according to the analogy suggested by the name of Mr. Kidd's crystalline principle.

As procured by the process described above, petroline forms foliaceous masses of small crystals of snowy whiteness, and bright pearly lustre. It is somewhat unctuous, and has a naphthous odor, which becomes very faint on exposure for some time to the air, and is removed altogether by boiling in alcohol. It fuses at 135° into a transparent, limpid, colorless fluid; but softens ten degrees lower. From a state of fusion it concretes on cooling into a translucent brittle mass, like wax, the density of which is 909 at 60° Fahr. At a temperature intermediate between the boiling point of water and a low red heat, the fluid boils, and distillation takes place. The greater part of the petroline condenses in the form of a fluid, which becomes, on cooling, a translucent waxy mass, with its original properties. But, owing to the elevated temperature required for its distillation, a part is decomposed, a little charcoal is left behind, and a small quantity of inflammable gas passes over with the undecomposed sublimate. When heated in the open air, it catches fire, and burns with a dense white flame and much black smoke.

Petroline is insoluble in water, cold or boiling. Boiling alcohol takes up a small quantity, not more than a 450th of its weight, and, on cooling, deposits the greater part in minute shining crystals. Boiling ether, its proper solvent, easily takes up a fifth of its weight, which, on cooling, is in a great measure separated in a congeries of micaceous crystals, so abundant as apparently to convert the ether into a solid mass. Oil of turpentine also dissolves it in large quantity, and so does naphtha.

Caustic potass and caustic ammonia in solution have no visible effect on this substance. When boiled with it, it simply fuses, rises to the surface, and is there found, on cooling, with its usual properties. Concentrated muriatic, nitric, and sulphuric acids, are equally without action, even when aided by the heat neces-

sary to boil each. It simply melts and rises to the surface, and, except that it becomes slightly yellow with nitric, and slightly brown with sulphuric acid, no change of property is perceptible. It has no action with acetic or oxalic acid.

With iodine, aided by a gentle heat, it quickly unites, forming a violet-colored fluid, which, on cooling, becomes a dirty greenish-brown solid, very soluble, like each of its elements, in sulphuric ether.

I have not made any inquiry into the other chemical relations of petroline, my object at present being merely to establish its claims to be considered a new principle, distinct from any other hitherto known. In its properties it resembles naphthaline more than any other substance; but, at the same time, it differs from that body in very many respects. Naphthaline volatilizes at common atmospheric temperatures; does not fuse under 180° Fahr.; and, when heated a little above 400°, boils and sublimes in fine micaceous crystals. It is heavier than water. It forms a rose-colored solution with acetic or oxalic acid; and with sulphuric acid it unites to form a peculiar acid, termed the sulpho-naphthalic, which, like other acids, neutralizes bases, and forms salts with them. A single glance will satisfy every one how completely this account of the properties of naphthaline differs from the description given above of the properties of petroline.

It remains for me to determine its elementary composition. This I have not hitherto found leisure to accomplish; but I am engaged in the requisite experiments at the present moment, and will soon make them known to the society. The experiments hitherto made merely enable me to say, that it contains a very large proportion of carbon.

*Appendix, December, 1834.*—A few months after the preceding paper was read before the Royal Society, the author observed in Buchner's Repertorium, an account of the discovery in 1830, by Dr. Reichenbach, of a crystalline principle in tar, to which that chemist gave the name of paraffine.\* As the properties of paraffine seemed from that account to be obviously identical with those of the petroline of the Rangoon petroleum, and as Dr. Reichenbach had ascertained its properties and composition fully, any farther investigation of the crystalline matter of petroleum appeared unnecessary. The original paper is now published, partly because allusions have been made to it in chemical works, and partly to serve as an introduction to the ulterior inquiry of Dr. Gregory on the same subject.

The author, soon after laying this paper before the Royal Society, examined by the same process the petroleum of St. Catherine's, near Edinburgh, of Rochdale, in Derbyshire, and of the island of Trinidad; but was unable to detect a similar crystalline principle in any of them.—[Transactions of the Royal Society of Edinburgh, Vol. xii., Part i., p. 118-123.]

\* A notice of Dr. Reichenbach's researches on Paraffine will be found in the Repertory, third series, vol. xv., p. 34, in the number for January, 1833.

ON THE FUSION AND APPEARANCE OF REFINED AND UNREFINED COPPER. By DAVID MUMMET, Esq.—The following are "a few extracts from experiments made some years ago, with a view to ascertain what effect would be produced upon the strength and malleability of copper, by retaining, to a certain extent, the alloy (chiefly tin) which is found in rough copper, and which it is the purpose of the copper refinery to discharge. In the first place, I obtained a quantity of shotted rough copper, made from the furnace in which the copper, though alloyed with other matters, first appears in its metallic form. These shots were light and flaky, hard when struck, but at the same time partially ductile. A quantity of pure shotted copper, made from the refinery, and having the form of flattened spheroids, and much denser than the other, was procured at the same time for the purpose of these experiments.

Exp. No. 1. A quantity of rough copper was fused in a black-lead crucible with nearly an equal bulk of charcoal, and poured into an open iron mould. The bar or ingot thus made was three-fourths of an inch thick, and when cold and broken, was found to have crystallized in converging striæ perpendicular to the upper and lower surfaces, and declining towards the outer edges of the bar. The grain was of a pale color inclining to gray, indicating the presence of tin.

Exp. No. 2. Three bars procured in this way were melted together in a black-lead crucible, without charcoal, and poured into a mould just at the moment when the melted copper put on a creamy appearance. When cold, the surface of the ingot thus obtained was less coppery-metallic than the surface of the ingot in the first experiment, where charcoal was used; from which it may be inferred that, owing to the absence of charcoal, a certain degree of refinement had taken place. The fracture possessed more of the red grain of good copper; the striæ were less distinct and less crystalline; and the surface, instead of being convex, as in the first experiment, was concave.

Exp. No. 3. Some of the pure shotted copper was fused in a black-lead crucible with an equal bulk of charcoal, and the resulting ingot presented a more clean and perfect mass of copper than the ingots obtained in Experiments No. 1 and No. 2. The fracture presented a series of brilliant striæ arranged from surface to surface, breaking off easily in the direction of the perpendicular fibre, a structure which seems wholly incompatible with extension or malleability.

Exp. No. 4. Some of the same pure copper melted similarly, but not poured into the mould until it had nearly lost its fluidity, formed an ingot less striated or crystallized than any of the former, with more of that minute deep orange-colored grain which is peculiar to pure and malleable copper. From the results of this experiment, and of No. 2, it would seem that when copper is poured into the mould

at as low a temperature as is consistent with perfect fluidity, the fracture is less crystallized, and the color approximates to that ruby grain which indicates the malleable state of copper.

Four bars, one from each of the foregoing experiments, were imbedded in burnt lime, shut up from the access of air, and exposed in crucibles to the same temperature. The pure copper bars (Nos. 3 and 4) were on the surface considerably oxidized, but those made from the rough copper (Nos. 1 and 2) were entirely free from oxide; and from this it may be inferred that the alloy (principally tin) which still remained in the copper, prevented waste or oxidation. The bar from Experiment No. 1 was not cut, but that from Experiment No. 2 retained about the same quantity of grained striæ as before the cementation; though, compared with a fracture of the same copper that had not been cemented, the grain was redder, the color more brilliant, and the metal more ductile. The bar from Experiment No. 3 was covered with a thin coating of crystallized oxide exceedingly soft; the striæ were more enlarged and adhesive, so that the copper, in cutting, tore out in flakes, which separately were soft and ductile. The bar from No. 4, when examined and compared with an uncemented one, was more open in the grain, redder, and more brilliant; but the quantity of depth of grain was nowise altered, although the metal cut softer, and was covered with a thin crust of shining oxide. From these details it may be presumed that cementation opens the grain, renders the bar less dense, but does not change the peculiar form of the arrangement. In each case, the copper after cementation was softer, a change which seems favorable to rolling cold. The impure or rough copper appears to be alloyed with another metal (no doubt tin,) which prevents that oxidation which pure copper in the same circumstances would undergo.

Besides the above, several bars were made from the rough copper by a slower fusion, and with a longer exposure to the charcoal, and it was observable, that the longer the exposure, and the slower the fusion, the more yellow and refined was the copper in the bar.

Some of the bars produced in the course of these experiments were attempted to be rolled; but the success was various. Of those made from the pure copper, some rolled better and others worse than any made from the rough copper; one or two bars of the latter were equally malleable with the former; but none rolled well either hot or cold. In those bars in which the striated arrangement was most perfect, the capacity for rolling was least, and those in which the minute granular fracture prevailed, generally rolled the best. It certainly does appear that (his tendency to crystallize, so destructive to malleability, is peculiar to English copper made from the crucible. There are occasions, no doubt, when, the proper temperature being hit upon, the bar would roll; but these occasions are so

rare and uncertain, that English copper made in this manner could not be relied upon in the manipulations connected with manufactures. There is no question that the arts in this country suffer from the peculiarity of English copper. For, in consequence of it the malleabilization of that metal is necessarily confined to the original process of refining practised on the great scale by the copper smelters. It is very different with Swedish and Russian copper, which I have seen melted in considerable quantities in large crucibles, cast into cakes or thick sheets, and afterwards rolled into boiler-plate and thin sheet-copper. This subject requires and deserves a scrupulous examination, with a view to discover the cause of the uniform tendency of English copper to crystallize; and that cause may, perhaps, be found in the process employed in this country for the smelting of copper ores, a process which, however economical and well calculated to overcome quantity, has never yet produced pure copper.—[London and Edinburgh Philosophical Magazine, May, 1835.]

[From the Journal of the Franklin Institute.]

*Abstract of the Specification of a Patent for a mode of manufacturing Wrought Nails, Tacks, or Spikes, by first preparing the material, rod, or pieces, from which they are to be made, in such a manner as greatly to facilitate the process of making them, and then operating upon the pieces so prepared by means of a machine particularly adapted to that purpose. Granted to WILLIAM C. GRIMES, York, York county, Pennsylvania, December 17th, 1834.*

The metal is first to be rolled or slit into rods, but not of the exact size and form of the body of the nail to be made, but they are to be broader one way, and thinner the other, the rods being usually about twice as broad as they are thick; the width and thickness of the rod, or piece, however, being such that, when it is staved, swaged, or compressed upon its sides, or edges, enough to bring it into a square form, it shall then be of the requisite thickness for the body of the nail, tack, or spike. The rod is to be cut off into the proper lengths for the nails, tacks, or spikes; they are to be cut square off at one end, the other being cut very obliquely across the rod, thus giving the requisite taper for forming the point to the nail, &c., which taper will be greater, or less, according to the obliquity of the cut across the rod. The nails, tacks, or spikes, so prepared, may be finished by various methods, as by forging, swaging, or compression; and the machinery to operate upon either of these principles, to effect the same end, is susceptible of an almost endless variety of modifications.

The machines that I have adopted for the purpose are made to operate upon the principles of swaging and compression, and are constructed as follows. The prepared piece is let or dropped into the upper end of an angular trough, or gutter, which stands inclined from a

vertical line about thirty degrees, (more or less.) The trough consists of two flat sides, joined at right angles, the angular point being downwards, so that, if the trough was placed in a horizontal position, its sides would rise at an angle of forty-five degrees from the horizon; the piece that forms this trough, or gutter, is the ridge, or rather one corner, of a triangular frame. Swages, or hammers, strike or act upon different sides of the nail as it descends along this trough, or gutter; these swages are placed in pairs, each pair striking upon the nail within the trough alternately, and consequently upon its different sides; their helves, at their outward ends, are jointed to the two lower angles of the frame, and in such position that they operate at right angles with each other.

The piece for the nail, &c., when dropped into the gutter, slides down to a moveable piece, or stop, that rises through the bottom of the trough, which arrests it for a moment, or until both swages have operated, when this stop recedes, and the piece instantly slides down until it is arrested by a similar stop, and is again struck by two other swages, and so on through any required number; three pair will, I apprehend, be sufficient in all cases. The last pair of swages, which are at the lower end of the trough, or gutter, fall upon, and grip the nail, while a heavy hammer, from below, strikes upon and heads the same. The heading hammer, swages, and stops, all receive their motion from cams fixed upon a revolving shaft, running up through the triangular frame. Two or more nails may be passing down the angular trough at the same time, as the stops, after allowing a nail to pass, immediately resume their position. The swages, hammer, &c., after being raised by the cams, are forced back upon the nail by suitable springs.

I intend sometimes to form or finish the nails by pressure, which is effected in the following, or in a similar, manner. The machine, when intended to finish the nail by pressure, is to be made, generally, like the preceding machine, but the triangular frame will be much shorter, as there will be the lower pair of swages only, the inclined trough, or gutter, having a single stop. The action upon the nail, &c., is to be very similar to that before described, being alternate, and upon different sides, but it is to remain in the same place till finished. After a few reciprocating or alternating motions of the jaws, one or both of them close or press upon the nail, and hold it whilst there is a head pressed upon it. In forming some nails, the alternating motion of the jaws may be unnecessary, as they may close upon the nail at once, and form it sufficiently by this single pressure.

There should be two pairs of shears for cutting off the rod, whether it is cut hot or cold; the cutting edges of these stand at right angles, or nearly so, but both pairs may be fixed upon short arms, standing out from a strong vibrating, or

semi-revolving, shaft; one pair to cut the rod off obliquely; and the other pair to cut it square. The two troughs, spouts, or gutters, into which the nails fall from the respective shears, may both lead to the same point, and terminate in one groove, or gutter, before it reaches the machine below.

I intend sometimes to cut the pieces for the nail from plates, instead of from rods. The plate should be of sound material, and rolled much broader than other nail plates. These plates are to be cut off transversely into pieces about two-thirds the length of two nails; from the sides or edges of these plates, the pieces for the nails are to be cut. The plate is to be held and turned over at each cut, in the manner followed in making cut nails, the length of nail, however, being only about two-thirds of the width of the plate; the shears being bent into such form as to run off to the edge of the plate; the piece thus cut off is brought to an acute point, being tapered less than half its length; the taper, or points, of the nails overlapping each other in the plate. This plate should be at a red heat when the nails are cut from it, if they are to pass directly into the machine; or they may be cut off cold, and afterwards heated and fed to the machine, as before specified.

What I claim as new, and as my invention, in the before described mode of preparing the pieces, or material, for wrought nails, and in the machine for finishing them, and for which I ask letters patent, is—1st, The cutting the rod obliquely, in the way described, to form in part, or wholly, the taper of the nail, tack, or spike, whereby mere pressure, or swaging, will suffice to finish the nail, &c.: the rods being broader one way, and thinner the other, than the body of the intended nail.

2d, I claim the manner of preparing the pieces for wrought nails, tacks, &c., to be finished in my machine, by cutting them out of plates of metal, as herein before shown. I do not claim the cutting with the grain of the metal generally, that having been previously done, but confine myself to the cutting into the form, and for the purpose, described. I claim the forming or finishing nails, tacks, or spikes, or other metallic articles, by swaging in, or as they descend an inclined trough, or gutter, after the manner, or upon the principle, herein before specified.

3d, I claim the finishing of nails, or similar articles, after being prepared as herein before shown, by alternate or simultaneous pressure, after the manner, or upon the principle, before specified.

WILLIAM C. GRIMES.

To the Editors of the *Mercantile & Advocate*.

Gentlemen: In your paper of Thursday, I observe you give "Indiana" credit for the following contemplated works:

1st. A steam-boat canal to unite the waters of the Lake with the Illinois River.

2d. A canal from Beardstown to the Sangamon River.

3d. A Railroad from Chicago to Galena, &c.

The above, and I believe all the improvements

you mentioned, are in Illinois exclusively, and with the exception perhaps of a small portion of the Chicago and Vincennes Railroad, are in contemplation. The Chicago and Illinois River Canal will probably be commenced in the spring, and would have been this spring had the Legislature given the Governor sufficient power to pledge the credit of the State for a loan to commence with. Your obedient servant, Illinois.

**NEW YORK AND ERIE RAILROAD.**—The people of the West look with earnest interest at the progress of this work,—not that it is of any consequence to us whether New York or Pennsylvania, which are engaged in honorable rivalry, shall secure our trade,—for the West will avail itself of the best accommodations afforded to it,—but that this Railroad will better serve our interests than any other work projected by either of these States. New York is the best and proper market for the West to go to. We would rather be conducted to that great central mart than any other. The New York Herald states that merchants from Tennessee, Kentucky, Ohio, and other regions, who have been in the habit of buying their goods in Philadelphia, are now purchasing them in New York, and remarks: "The whole commerce of the nation is fast concentrating here. This is the great mart of commerce—and the coming season will prove it." The indications of fall trade are said to be beyond any hitherto known, and the papers speak with exultation of the influx of trade from the West. But the spring trade: let us be accommodated here. This region will soon find it more profitable to get their spring goods through other channels, than to be retarded some five weeks in the opening of their trade, by the obstructions in Buffalo harbor, which last season was not cleared until the 15th of May. We believe it to be the unanimous opinion of merchants here, that their interests are intimately connected with the completion of the New York and Erie Railroad, which would place their spring business at least one month in advance of what it now is.—[Chicago American of 29th Aug.]

We are glad to see by the number of wooden blocks piled up in the rear of the Old Bridewell, that the experiment of paving a part of Broadway with wood, on the Russian plan, is in a fair way of soon being tried. Should the attempt prove successful, it will bring about a complete revolution in the mode of paving streets, and will form an improvement of vast importance. [We understand that the part of Broadway selected for the experiment, is in front of the two squares next above Murray street. Each of the small blocks of wood is of hexagonal shape; the whole are to be fitted together and driven up tightly, by a long strip of timber near the gutter at the sides; and the interstices between the blocks to be well payed with tar of pitch.—[Gazette.]

**CANAL TOLLS.**—There has been received for tolls on the New-York canals from the 15th to the 31st August, the sum of \$93,544 72. Add to this sum the tolls for the first two weeks, \$67,792 81, and it makes the total receipt for the month of August, \$161,337 53. This exceeds the collections for Aug. 1834, by the sum of \$24,649 70.

There has been received for tolls on all the State canals from the opening of navigation to the close \$863,228. This exceeds the collections up to the same time in 1834, by the sum of about \$154,000.—[Argus.]

A statistical account of the steam-engines in existence in France, taken under the direction of the Administration des Mines, has been completed up to the end of 1833, when there were 947 steam-engines, presenting together a force of 14,746 horse power—a single horse power being estimated at 75 kilogrammes, or 165 lbs. avoirdupois, raised to the height of a metre, or nearly four feet to a second.—Of these engines, 759 were made in France, 144 abroad, and 44 whose manufacture has not been ascertained. This account shows that in all the years from 1827 to 1833 inclusive, the last year was that within which the greatest number of engines has been erected. These amounted to 130, of which five only were of foreign manufacture. It also shows that of the 903 engines whose manufacture has been ascertained, 334 were of low-pressure, and 569 of high-pressure. These 903 engines form the total of those which have been constructed within

the last twenty years, and it is only during the last four or five years that the immense advantages of the high-pressure engines have been fully acknowledged; and, consequently, the greater number of the 569 high-pressure engines have been formed during this last period; so that the present proportion is not as 334 to 569, but as 1 to 3 or 4. However this may be, it is proved that there are now in use in France a great many more high-pressure than low-pressure engines. On the 1st January, 1834, there were in France 95 steam-vessels, besides those in the service of Government. The engines they employ are 118 in number, of which 82 are on the low-pressure, and 36 on the high-pressure principle. But it is remarked that these vessels have been built a long time, and therefore when the low-pressure principle was most in favor. Of these 118 engines which present a force of 3,480 horse power, 34 have been ascertained to be of French construction, 59 foreign, and the remaining 35 are unknown. At present the engines constructed in France in proportion to those made abroad is not as 34 to 59, but as 128 to 61. Therefore the engines on board the steam-vessels which are of foreign manufacture are of an old date, and of a period when high-pressure engines were but little used.

**LIVERPOOL, WEDNESDAY.**—THREE WAGONS DESTROYED BY FIRE ON THE RAILWAY.—One of the engines of the Liverpool and Manchester Railway left the latter place this morning at five o'clock, with three wagons attached, containing about 80 packages of goods, principally intended for shopkeepers in this town and Glasgow; on approaching the Whiston inclined plane, about half mile from Liverpool, the wagons were discovered to be on fire, and before any effectual assistance could be given, the whole were enveloped in flames, and all the goods destroyed, amounting, it is supposed, in value to 2,000*l*. It has not yet been ascertained correctly how the accident originated, but it is supposed to be from friction, owing to the great speed at which the train was travelling. The Railway Company intend paying the respective owners of the goods the full amount of their losses.

**EXPEDITION TO THE EUPHRATES.**—Some time, we fear, must elapse before the necessary preliminaries are arranged for the progress of this expedition. A letter from Constantinople states, that the Grand Seigneur had intimated to the Pasha of Egypt, by a Tartar, despatched on the 24th of June, that he could not prescribe the course to be pursued, until a reply was received from the government of England to certain propositions submitted to it.

**MECHANICS IN SAILING.**—The "Biblioteca Italiana," gives a detailed description of "the application of a windmill to the motion of vessels at sea, invented by Signor Giuseppe Brusetti, engineer." The vessel has two paddle-wheels like a steamboat, and the mechanism of the windmill is so contrived, that if there is any wind at all, from whatever it may blow, the vessel is propelled by the action of the sails, and may be steered in whatever direction is desired.

**LUCIFER MATCHES** would seem, according to the annexed paragraph, to be suspected at Bremen, as well as at Amboy, as of dangerous character.

**HAMBURG, July 21.**—The magistrates of Bremen have issued a very rigorous prohibition of the newly invented lucifer matches, on account of the danger of fire which they may occasion by spontaneous combustion.—[Hamburg Paper.]

#### AGRICULTURE, &c.

[From Hovey's Gardener's Magazine.]

*Notices of some of the Gardens and Nurseries in the Neighborhood of New-York and Philadelphia; taken from Memoranda made in the Month of March last.*

[Continued from page 553.]

**LINNEAN BOTANIC GARDEN AND NURSERY, LONG ISLAND: WILLIAM PRINCE & SONS, Proprietors.**—This extensively known establishment, though the last named in our remarks, will not by any means be considered the least in its character. It is one of the oldest nurseries

in the country, and also one of the most extensive, if not the very largest. It was established by the father of one of the present proprietors, and has become a family inheritance. When we take into consideration all that has been said in regard to this place, either by the proprietors themselves, or by the persons who have frequently visited it, among whom have been some very intelligent and able gardeners, who have visited this country, we feel ourselves almost incompetent to speak of the establishment, for fear that in our impartiality we might not be thought to do justice, by the proprietors, or be said to give too much praise by others. Much has been written in relation to it in *Loudon's Magazine*; and for a time, several communications appeared under various signatures, in regard to its extent and the variety of plants it contained.

We stated, when we commenced our remarks, that we should confine them chiefly to the appearance of plants in the green-houses, hot-houses, &c. We shall not at this time say any thing as regards the extent of this nursery, the variety of hardy plants it contains, or of its immense number of correspondents, agents, &c. We hope at another opportunity to do this, and to do it with justice and candor; we passed an hour or two in walking through it in the fall of 1831, but it is, we have understood, much improved since then; we know that the Messrs. Prince are too liberal not to give every indulgence for our statements. Mr. W. R. Prince informed us, the past spring, that as soon as circumstances would permit, he intended visiting England, and the Continent, partly with a view of becoming more acquainted with horticulture, and for the purpose of noticing the extent and variety of plants contained in their gardens and nurseries. He kindly promised to contribute to our pages, and our readers will, we have no doubt, be gratified with his remarks. The Messrs. Prince have lately added to their business as nurserymen, that of the seedsman, and are dealing largely in seeds.

The extent of glass, including the conservatory, green-houses, hot-house, frames, &c., we should judge to be upwards of four hundred feet in length. One of the houses, in which are kept the orange and lemon trees, is built in the old style, with large upright front sashes, and a dark roof. The collection of oranges and lemons is very large, and includes many more distinct varieties than any other we have ever observed; in their catalogue they enumerate upwards of seventy kinds; they are well grown, and many of them beautiful shaped plants. We saw an immense number of seedlings intended for stocks, to bud, or inarch upon. Messrs. Prince have been at great expense to procure from the Italian nurseries, which excel in this grand fruit, nearly all that are worthy of cultivation. Here we also noticed a fine stock of the different varieties of the magnolia, of which there is a large number of kinds, including the *M. Soulangeana*. Hundreds of plants of the *Gardenia florida* and *G. radicans*; of the

different species and varieties of myrtles, a good stock.

It cannot be expected that in an extensive establishment like this, there would be many flowers in bloom. In the green-house, however, which adjoins the orangery, we saw one of the finest specimens of *Acacia verticillata*, profusely covered with its showy blossoms; *Metrosideros lanceolata*, and some species of *Banksia*, of which there were many plants, were also in flower; that much sought-after plant, the *Epacris grandiflora*, with its exquisite tubulous, rosy white blossoms, was in full bloom. Here was a fine collection of geraniums and a good variety of *Ericas*, though small plants. In the hot-house, which adjoins the green-house, and completes one range, we noticed several beautiful ferns. A good stock of that magnificent bulb, the *Crinum amabile*; some *Kämpferias*, *dracenas*, &c., young plants of the banana (*Musa sapientum*), several species of the cacti. In the Camellia house, not more than five or six plants were in flower; among them, however, was the *C. althæflora*, with several blossoms expanded; it is a brilliant kind, raised by the Messrs. Chandler, about the same time of the corallina, with which it is nearly equal in beauty; the others were the common varieties. The stock of camellias is probably the largest in the country, and includes the most rare. The reason why more camellias were not in flower, was from the cause that the shutters on the glass were not taken off for several days together, and the house kept as cool as possible, without endangering frost.

From the Camellia house, we entered another green-house filled with a variety of plants: myrtles, eugenias, azaleas, and a good stock of other kinds, which we do not recollect the names of. A few camellias which were placed here were in bloom, among which was the *C. Woodsii*, *maliflora*, and others; several species of *brunia* were prettily in flower. We were particularly struck by observing the very large number of some kinds of plants which the Messrs. Prince have in their collection, and we could enumerate many varieties; but they would not perhaps interest our readers, as most of them may be found in their catalogue.

In the frames, of which there were several, we found a good stock of Chinese roses, seedling magnolias, rhododendrons, and other plants. There was also a number of hardy shrubs and plants, which were laid in for executing orders to the south during winter, when they could not be taken from the open ground. When we visited this place a year before, we think the green-house plants, generally, looked in rather better health than they did the past spring; the gardener was at the former time repotting the whole of the camellias, and many other plants which had suffered from the want of it. Mr. Prince, Jr., informed us, upon our mentioning to him this fact, that their former gardener was very intelligent and well acquainted with his profession, but that he had left them; and

they had not yet procured another, as they expected one from England. We wonder at the good order which already exists, when we consider the multiplicity of avocations which must ensue, from the nursery and seed business combined.

We have thus completed our remarks, which have extended to a greater length than we at first anticipated, and perhaps farther than has been interesting to all our readers. Some would, probably, have rather read practical communications on the management and growth of plants, or the treatment of some objects of more utility; while others have been gratified in reading the advancement made in Horticulture and Floriculture by their neighbors. The object of a periodical Magazine is not to detail practices already well known, and laid down in works devoted to the subject of which it treats; but rather to give information of all new discoveries, and to record every improvement which may be found useful and advantageous to the scientific or practical gardener. These at first, however trifling they may often seem, when fully proved by repeated experiments, and correct observation, result in the foundation of some methods much more valuable, and of more immediate utility, than those previously adopted. The knowledge of gardening, like every other art, can only be advanced to any degree by calling in the assistance, and bringing to bear upon it those others, which enlighten, and throw some information upon its various branches. We therefore think, that those persons who suppose that mere practical papers are all that should fill the pages of a Magazine, take altogether a narrow and quite unconfined view of the subject; and that they have not yet made that progress in Horticulture, that enables them to see that its thorough knowledge, and proper application, is only to be obtained by acquiring some information of those sciences, without which it would be a tedious and uninteresting study, rather than one of the most pleasing and agreeable.

These observations are not made on the supposition that any such objections have, or will be heard; but to show how far we think a Magazine should extend its character. As regards the visiting of gardens and nurseries, we cannot here omit to urge upon every amateur, or lover of Horticulture, and more particularly every practical gardener, the importance resulting from such a course; not only should those in the vicinity of their situation be often inspected, but a tour should be made every few years to all those within the middle and northern sections of our country. To be confined to one spot, and to know nothing, but what may be learned from reading of what is done at other places, deprives one of all ambition, or of any desire to excel in his profession. An amateur gardener may imagine that he excels in the cultivation of a certain class of plants, and makes no effort to attain a greater degree of perfection; but when

he sees that another equals, his ambition is touched, and he is stimulated to greater exertion. It is from seeing and comparing, that we know our faults and learn how to improve and correct them.

#### NEW-YORK AMERICAN.

SEPTEMBER 5—11, 1835.

#### LITERARY NOTICES.

**LEGACY FOR YOUNG LADIES, AND EVENINGS AT HOME, &c., &c.,** by the late Mrs. BARBAULD. 1 vol. N. Y. HENDERSON GREEN.—This is a republication of an old volume—old at least in this day of rapid succession of novelties. The pieces of which it is composed were found among Mrs. Barbauld's papers, and were given to the world under the sanction of Miss Lucy Aikin. The following is quite a pleasant paper, and inculcates a good lesson for being agreeable in society.

**PIC-NIC.**—Pray, mamma, what is the meaning of pic-nic? I have heard lately once or twice of a pic-nic supper, and I cannot think what it means; I looked for the word in Johnson's Dictionary, and could not find it.

I should wonder if you had; the word was not coined in Johnson's time; and if it had been, I believe he would have disdained to insert it among the legitimate words of the language. I cannot tell you the derivation of the phrase; I believe pic-nic is originally a cant word, and was first applied to a supper or other meal in which the entertainment is not provided by any person, but each of the guests furnishes his dish. In a pic-nic supper one supplies the fowls, another the fish, another the wine and fruit, &c.; and they all sit down together and enjoy it.

A very sociable way of making an entertainment. Yes, and I would have you observe, that the principle of it may be extended to many other things. No one has a right to be entertained gratis in society; he must expend, if he wishes to enjoy. Conversation, particularly, is a pic-nic feast, where every one is to contribute something, according to his genius and ability. Different talents and acquirements compose the different dishes of the entertainment, and the greater variety the better; but every one must bring something, for society will not tolerate any one long who lives wholly at the expense of his neighbors. Did you not observe how agreeably we were entertained at Lady Isabella's party last night?

Yes; one of the young ladies sung, and another exhibited her drawings; and a gentleman told some very good stories.

True: another lady who is much in the fashionable world gave us a great deal of anecdote; Dr. R., who is just returned from the continent, gave us an interesting account of the state of Germany; and in another part of the room a cluster was gathered round an Edinburgh student and a young Oxonian, who were holding a lively debate on the power of galvanism. But Lady Isabella herself was the charm of the party.

I think she talked very little; and I do not recollect any thing she said which was particularly striking.

That is true. But it was owing to her address and attention to her company that others talked and were heard by turns; that the modest were encouraged and drawn out, and those inclined to be noisy restrained and kept in order. She blended and harmonized the talents of each; brought those together who were likely to be agreeable to each other, and gave us no more of herself than was necessary to set off others. I noticed particularly her good offices to an accomplished but very bashful lady and a reserved man of science, who wished much to be known to one another, but who would never have been so without her introduction. As soon as she had fairly engaged them in an interesting conversation, she left them, regardless of her own entertainment, and seated herself by poor Mr. —, purely because he was sitting in a corner and no one attended to him. You know that in chemical preparations two substances often require a third, to enable them to mix and unite together. Lady Isabella possesses this amalgamating power:—this is what she brings to the pic-nic. I should add, that two or three times I observed she

dexterously changed topics, and suppressed stories which were likely to bear hard on the profession or connexions of some of the company. In short, the party which was so agreeable under her harmonizing influence, would have had quite a different aspect without her. These merits, however, might easily escape a young observer. But I dare say you did not fail to notice Sir Henry B.—'s lady, who was declaiming with so much enthusiasm, in the midst of a circle of gentlemen which she had drawn around her, upon the *beau ideal*.

No indeed, mamma; I never heard so much fire and feeling:—and what a flow of elegant language! I do not wonder her eloquence was so much admired.

She has a great deal of eloquence and taste: she has travelled, and is acquainted with the best works of art. I am not sure, however, whether the gentlemen were admiring most her declamation or the fine turn of her hands and arms. She has a different attitude for every sentiment. Some observations which she made upon the beauty of statues seemed to me to go to the very verge of what a modest female will allow herself to say upon such subjects,—but she has travelled. She was sensible that she could not fail to gain by the conversation while beauty of form was the subject of it.

Pray what did —, the great poet, bring to the pic-nic, for I think he hardly opened his mouth?

He brought his fame. Many would be gratified with merely seeing him who had entertained them in their closets; and he who had so entertained them had a right to be himself entertained in that way which he had no talent for joining in. Let every one, I repeat, bring to the entertainment something of the best he possesses, and the pic-nic table will seldom fail to afford a plentiful banquet.

**THE BEAUTIES OF WASHINGTON IRVING.** 1 vol. 18 mo. Phil. CAREY, LEA & BLANCHARD.—What sad havoc does a bookseller's title make, sometimes with the modesty of an author. Here, from the stern necessity of complying with the requisitions of the law of copyright, on the one side—and of acquiescing, on the other, in the bookseller's fancy, we have our diffident countryman, actually taking out in his own name, a copyright for his own 'beauties.' This should have been otherwise ordered. Bating that, the little volume before us furnishes charming extracts from the various pages of Irving's works, principally his earlier ones, and may be said, in truth, to present many beauties. We make room only for one, which is a little Shandean.

**THE WALTZ.**—As many of the retired matrons of this city, unskilled in "gestic lore," are doubtless ignorant of the movements and figures of this modest exhibition, I will endeavor to give some account of it in order that they may learn what odd capers their daughters sometimes cut when from under their guardian wings. On a signal being given by the music, the gentleman seizes the lady round her waist; the lady, scornful to be out-done in courtesy, very politely takes the gentleman round the neck, with one arm resting against his shoulder to prevent encroachments. Away then they go, about, and about, and about—"About what, sir?"—"About the room, madam, to be sure. The whole economy of this dance consists in turning round and round the room in a certain measured step, and it is truly astonishing that this continued revolution does not set all their heads swimming like a top; but I have been positively assured that it only occasions a gentle sensation which is marvellously agreeable. In the course of this circumnavigation, the dancers, in order to give the charm of variety are continually changing their relative situations,—now the gentleman, meaning no harm in the world, I assure you, madam, carelessly flings his arm about the lady's neck, with an air of celestial impudence; and anon, the lady, meaning as little harm as the gentleman, takes him round the waist with most ingenious modest languishment, to the great delight of numerous spectators and amateurs, who generally form a ring, as the mob do about a pair of amazons pulling caps, or a couple of fighting mastiffs. After continuing this divine interchange of hands, arms, et cetera, for half an hour or so, the lady begins to tire, and "with eyes upraised," in most bewitching languor, petitions her partner for a little more support. This is always given without hesi-

tration. The lady leans gently on his shoulder; their arms entwine in a thousand seducing, mischievous curves—don't be alarmed, madam—closer and closer they approach each other, and in conclusion, the parties being overcome with ecstatic fatigue, the lady seems almost sinking into the gentleman's arms, and then—"Well, sir! what then!—Lord! madam, how should I know.

**THE HISTORY OF THE CONDITION OF WOMEN IN VARIOUS AGES AND NATIONS,** by Mrs. D. C. CHILD, 2 vols.: Boston, J. ALLEN & Co. Mrs. Child has earned an enviable reputation by former publications, especially "The Mother's Book."—In that now before us, she essays a task which well becomes a woman's hand, to trace the history of her own sex, at different times, and among different nations. This will be read, we are bound to presume with interest, by the ladies, for what it says of their own sex, and by the gentlemen, for what it says of the other. The range taken by Mrs. Child is very extensive, both as to time and to countries. Looking to what was said of American women, we find the following among other statements.

As a general rule, education among the wealthy classes is much more neglected in the slave states than in other portions of the Union. This is owing partly to the want of schools and partly to the indolence induced by slavery. It is a common thing, even for the wives and daughters of distinguished men, to be as deficient in correct spelling, as they are in a knowledge of household duties. But many are sent to the free states for education; and not a few are admirable exceptions to the above remarks. The southern ladies in general are delicately formed, with pale complexions, a languid gracefulness of manner, and a certain aristocratic bearing, acquired only by the early habit of commanding those who are deemed immeasurably inferior.

The woman of the United States have no direct influence in politics; and here, as in England, it is deemed rather unfeminine to take an earnest interest in public affairs. But perhaps there is no country in the world, where women, as wives, sisters, and daughters, have more influence, or more freedom.—Some travellers have compassionated the condition of American women, because they spend so small a portion of their time in amusements; but this remark applies equally to men; and it could not well be otherwise in a country where so much is to be done, and where estates are so equally divided that few become very wealthy. It is true that Americans do not treat their women with the graceful gallantry of Frenchmen, or the chivalric deference of Spaniards; but in place of these external refinements, women have their respect, esteem, and undoubting confidence.

The class who are exempt from personal exertion, or at least from personal superintendence of their domestic avocations, is comparatively very small. Labor in open fields and streets is rarely performed by women, unless it be by foreign peasantry lately arrived in the country. The buxom daughters of the Dutch farmers do indeed continue the old custom of raking hay, and the girls in Westchesterfield, Connecticut, may often be seen at early dawn weeding the immense beds of onions, for which that town is celebrated. A large proportion of schools throughout the country are kept by women, and it is not uncommon for them to keep shops for the sale of English and French goods, toys, confectionary, &c. Mantua-making and millinery are, of course, their peculiar province; and many are employed to tend looms in factories, to set types in printing offices, and fold sheets for the bookbinders. By far the largest portion of these do not work for support, but to gain additional luxuries, which their parents cannot afford to furnish. Nothing surprises a foreigner more than the near approach to equality in the dress of different classes. The rich and fashionable are in most respects like those of Europe; and humble imitators have need of great diligence to copy their frequent changes. In the article of jewels, the most wealthy cannot indeed cope with their European models; for the diamonds of a foreign duchess often surpass in value the whole fortune, real and personal, of a rich American.

The habit of tight lacing, in order to form a slender waist, has been copied, like other European fashions. This practice, combined with the habit

of taking very little exercise in the open air, has an unfavorable effect upon freshness of complexion and beauty of figure. Excursions on horseback have lately become a very favorite amusement with American ladies.

In a country where the price of labor is so high, it is no uncommon thing to see domestics dressed as well as their employers. But though silk gowns and laces have taken the place of coarse calicos, the situation of domestics is by no means improved. They are less contented in their situation, and less conscientious in the discharge of their duties, than they were in more patriarchal times. Many attribute this difficulty to our democratic institutions; but I believe it originates in a want of republican principle, and not in the excess of it. If people would consider their domestics as sisters of the great human family, differing from them only in having, for the time being, a different use to perform in society—if they would have a tender regard to their health, a reasonable regard to their convenience, a friendly interest in their characters and plans—in a word, if they would perpetually acknowledge a reciprocity of duties—we should soon cease to hear complaints of the indifference and carelessness of domestics. While they are regarded as pieces of machinery, to whom nothing is due but the payment of wages, they cannot be expected to feel a deep interest for those who manifest so little interest in them.

American ladies are accused of being more prudish than foreigners. I hope the charge will always remain a true one; but there may be an excess even of a good thing; and when a sense of decorum led them to be squeamish about seeing Greenough's beautiful cherubs, because the marble innocents had no drapery about them, I acknowledge it reminded me of Sir Charles Grandison's remark: "Wotest thou not, my dear, how much delicacy there is in thy delicacy?"

The tendency of modern times has continually been toward external refinement. The language used by queen Elizabeth and the queen of Navarre would not now be tolerated in any part of the world; yet the marriage of a divorced wife aroused more virtuous indignation in the court of Elizabeth, than a dozen such incidents would now occasion, in any European court. Many phrases and subjects of conversation which appear perfectly proper to an English or French woman, are not so considered by an American.

**THE AMERICAN MONTHLY MAGAZINE**, for September. Edited by C. F. HOFFMAN, and H. W. HERBERT. New York, GEO. DEARBORN.—A very good number—though to that, we are becoming so accustomed, in speaking of this periodical, that it ceases to sound like praise.

The Enquiry concerning the guilt of *Catharine Howard*, one of the fairest of the many wives sacrificed to the lust and ambition of Henry VIII., is curious—and the vindication at this late day of her innocence, in the face of all the historians of that period, is, to say the least, adventurous. The effort of the writer, a lady, is, to make out that she was the victim of a Protestant conspiracy, in which *Cranmer* was a chief instrument. This will, with difficulty, obtain credit now, however ingeniously it may be argued—and as to proof, there is and can be none. We extract the substance of this vindication.

During this year, (1541) the King went to York to hold an interview with his nephew, the King of Scotland; and it was whilst in that city, and influenced by his Catholic advisers, that he issued out a proclamation that all who had been aggrieved for want of justice should come to him and his council for redress. "His aim," says Rapin, "was to throw all past miscarriages on Cromwell, and put his subjects, particularly the northern people, (amongst whom there had been numerous insurrections), in hopes of better times." *Cranmer* and the rest of the Reformers had not accompanied the King to York; they had remained in disgrace in London, or at a distance from the Court; therefore these, the only popular acts of Henry after his divorce from *Catharine of Aragon*, cannot by any possibility be attributed to them.

But, thus banished from court and driven from the councils of the King, what were the feelings of the Reformers? They saw their opponents triumphing in their disgrace: they must not only

give up all hopes of carrying on the work of spoliation and plunder, but they stood a chance of being called upon to refund what they had already appropriated to themselves; or they must contrive some means to destroy the influence of the Catholics with the King, and to kindle his wrath against all of that persuasion who possessed credit and power. It would not do to intrigue against any person comparatively indifferent to Henry, for should they even be successful whilst *Catharine* possessed the King's affections, other Catholic ministers would without doubt succeed those in present favor. They knew well Henry's jealous and irritable temper; they knew his fastidiousness with regard to female honor and delicacy: on these they relied for the fortunate issue of their plot. Had *Catharine* lived now, the press, with its three hundred newspapers might have saved her. Since his marriage, the King had daily blessed God for the happiness he had enjoyed with his Queen; and during his journey to York, to express his extreme satisfaction, his esteem and tenderness for her, he enjoined the Bishop of Lincoln, his confessor, to draw up a particular thanksgiving. Fond, however, as Henry is always acknowledged to have been of this wife, some part of the happiness he enjoyed it is reasonable to attribute to his having escaped from the councils of the Reformers, and to his being surrounded by those whose object was to promote the happiness of the people, from which that of the sovereign is inseparable.

It was during the visit to York that the Protestant plot against the life of the Queen was planned; and on the return of the court to London it was put in execution, and a bungling affair it was, affording but small credit to the genius for intrigue of its originators. John Lassels, a brother to a discarded servant to the old Duchess of Norfolk, and who, it is reasonable to suppose, was a Catholic, by his being in the service of the highest Catholic family in the kingdom, came to *Cranmer*, a Protestant and persecutor of Catholics, and told him in confidence what he had heard his sister say respecting the lewdness of the Queen previous to her marriage! Who would now credit such hearsay evidence?—We are not, however told why, if this man (*Lassels*) thought his secret such a mighty important affair, he had not communicated it previous to the marriage instead of about a twelvemonth after; or why he did not select some honorable Catholic nobleman to confide it to, instead of *Cranmer*, whom, if a Catholic, he must have looked upon as little better than the arch-fiend himself. But such a one would have been rather cautious how he gave credence to the slander of discarded menials.

*Cranmer* took upon himself the amiable office of undeceiving the King with respect to the virtue of the Queen, and was near paying with his life the penalty his baseness merited; for Henry disbelieved every word of the statement made to him. Proofs must now be had, for the conspirators stood in a perilous situation. Witnesses were sought where alone they were to be purchased—amongst disgraced menials and the lowest refuse of society. Bribery and corruption were set to work, and it is not improbable that the wealth of which the Catholic Church had been despoiled, was now employed to bring the head of a beautiful and innocent Catholic Queen to the block. Henry, we are told, burst into tears when he was told of the Queen's misconduct. But his jealousy and violent passions made him fall into the plot of the Protestants; their aim was now attained, and all the rest was easy.

*Cranmer*, his great supporter, the Duke of Suffolk, the Bishop of Winchester, and *Writchesley* Earl of Southampton, who had shared so much of the plunder of the church, who had gained possession of the property and revenues of the Abbey of Winchester, and of the manors of *Micheldever* and *Stratton*, once the private property of the immortal *Alfred*, were the persons appointed to examine the Queen. What justice had she to expect at such hands? When first accused, we are told she denied all guilt; but on her second examination she is said to have confessed, though neither the bill of attainder passed against her, nor the journals of Parliament state what she confessed. She was condemned by a secret tribunal, in direct violation of the laws of the country, and the members of which were the bitter enemies of her religion and of her family, instead of being tried, according to law and justice, before the peers of the realm. She was found guilty upon such evidence as would not be received in a court of justice in the present day, without a single advocate to plead her cause and demand for her justice—not even two such doughty

heroes "as kept together in their chivalry,"\* on a late similar occasion.

The venerable Dutchess of Norfolk was condemned to be beheaded for not informing the King of her grand-daughter's incontinence before marriage; but this act was so odious to the nation, that it was thought prudent not to put it into execution, and the Dutchess only suffered a long imprisonment. But the scaffold was deluged with blood, amongst which streamed some of the noblest in England. The name of *Catharine Howard* has been linked with infamy, and to the success of this Protestant plot may be attributed all the penal statutes and cruel persecutions that the Catholics endured in England and Ireland for near three hundred years.

**THE AUTO-BIOGRAPHY OF WASHINGTON WILKING** is from a skilful pen, as the annexed portion will prove, the whole scene is life-like.

It was soon after the lamentable affair of General Hull had been bruited abroad through the country, awakening everywhere mingled feelings of grief, dismay and indignation, that the students of our college, were one Sunday collected in the village church, whose white spire shot above the elms that surrounded it, within a few yards of the institution. The discourse of the preacher was suggested by the then alarming condition of the country, and the fervid puritan dwelt upon the duties which became each citizen of the republic at such a crisis, with an emphatic sternness which would have put some thoughts of iron into the most fainting bosom. He commenced, I well remember, by deploring the original declaration of hostilities, which he averred was based upon grounds that at the least were questionable. But he insisted that, however good men might have wished to keep off so calamitous an event, yet, as it could only overtake them at last by the consent of Providence, it was their duty not to shrink from its decrees under any extremity; that it was the will of Heaven that we should pass through another trial like that our fathers had endured, and it mattered not whose act had precipitated the moment of that trial; that our duty to God and our country alike required that we should now fling all thoughts but of them behind us; that we should go forth as one man to meet the invaders of our soil, and leave the rest to Him whose blessings descend alike in the sunshine and the storm, at the unsullied altar and upon the blood-stained battlefield!

The clear note of a bugle rang through the village as the patriot clergyman here paused to add the final blessing of the service. The tramp of armed men was heard in the threshold of the church, and the summer breeze that floated through the open porch unfurled the proud standard of our country as, with uncovered heads, a band of regulars formed in silence before the door. The lips of the preacher had not yet begun to move in prayer, as with uplifted hands he bent forward towards the glorious emblem of our Union, before the young and the old, the sturdy yeoman and the strapping student, the bright village maiden and her hoary sire rose, as by one impulse, to their feet; and not an eye in that assembly but glistened, not a heart but vibrated while their pastor poured forth his thrilling appeal to Heaven for a blessing on that banner wherever its folds may wave.

The congregation was dismissed. The recruiting party—for such it proved to be—filed slowly away from the church door, and winding down a green lane hard by, soon disappeared behind the copses by which it was skirted. The rustic equipages of the farmers who lived remote from the meeting were drawn from the low shed beside it, and as each received its freight in decorous silence they trundled off at measured intervals through the main street of the village. The young men of the congregation appeared to linger about the church, as grouped here and there beneath the cloistered boughs of the ancient elms, they were engaged in low and earnest discussion. At last these also disappeared, and though the light laugh of some giddy maiden might reach the ear, as her white dress fluttered for a moment above the stile, while taking her way homeward across the fields, yet the calm of a New England Sabbath soon settled over the place, and left the landscape to the repose of summer noontide.

Five days afterward, and what a different scene

\* In one of Lord Denman's speeches, alluding to the trial of Queen Caroline, he said, he and Lord Brougham "had kept together in their chivalry."

was there presented! A company of raw volunteers was forming upon the green esplanade in front of the meeting-house, preparatory to their taking up their line of march to join the Northern army, whose active campaign had just opened.—There were but sixty of us altogether; and though among them were several students from other parts of the Union, yet the majority were the flower of the youth of the adjacent country.

**BEAUTIES OF WASHINGTON IRVING.**—The selection bearing the foregoing title was not made by Mr. I. It originally appeared in England, and was the piratical act of some English bookseller. A copy was stereotyped by some American publisher, and was about to be put to press in this country when he was informed that he would be liable to, prosecution for infringing the copy rights of the works selected from Mr. I. purchased the plates to destroy them. He was afterwards induced to permit his regular publishers, Messrs. Carey, Lea & Blanchard, to issue an edition for their own benefit. The copy right was taken out and advertised by Mr. I's agent, without his knowledge.

This explanation, derived from an authentic source, is due to Mr. I., that he may not stand chargeable with the indicacy of selecting and pointing out any portions of his writings, as "beauties," and is the more proper at our hands, because of the remarks we made on this little volume on Saturday.

#### EUROPEAN INTELLIGENCE.

**LATEST FROM EUROPE.**—The packet ship Columbus, of 1st August, from Liverpool, brings our London papers up to that date.

The explosion in Paris, of a new sort of infernal machine, calculated apparently to sweep the whole Orleans dynasty at one blow from the earth, is the chief item of intelligence. This attempt, of which the particulars will be found among our extracts, was made on the anniversary of one of the glorious three days, and caused, as will be seen, the instant death of old Mortier, Duc de Treviso, and several other officers in the staff of the King. None of the Royal family, however, though all the male part of it were in the cortege, sustained any injury.

The act would seem to have been one of individual vengeance, and was contrived certainly with very deadly purpose and skill.

The remarkable preservation of all the Royal family will serve to confirm their power, as being, as it will be represented with more than ordinary proofs to be, under the immediate protection of Heaven.

Of other news we find little of interest.

[From *Galignani's Messenger*, Paris, July 29.]  
**ATTEMPT UPON THE KING'S LIFE BY AN INFERNAL MACHINE.**

"It is with the deepest concern that we lay before our readers the details of the above horrible event, that took place yesterday, (July 28th.) After having passed along the Boulevard to the furthest point at which the national guards and the troops were drawn up, his Majesty, accompanied by the Duke of Orleans, the Duke de Nemours, the Prince of Joinville, and a numerous and brilliant staff, was returning along the same line to the Place Vendôme, where the troops were to file off before him. At 12 o'clock, at the moment when he had reached the Boulevard du Temple, a little before the Theatre des Fumambules, a tremendous explosion resembling regular platoon firing was heard. At first it was supposed to be a discharge of fire works, but the falling and cries of the victims soon revealed the reality, and excessive confusion ensued—an infernal machine had just poured forth a shower of balls upon the cortege that surrounded the King! Marshal Mortier, Duke de Turin, fell and expired without a word. Several other officers, and some of the National Guards were also killed, and a considerable number wounded. The falling of some horses, among which was that of Marshal Mortier, and the capering of others, added to the tumult—which it would be diffi-

cult to describe. During this scene, the King, whose arm had been grazed by a bullet, and whose horse had received a wound in the neck, maintained the calmness for which he is distinguished, and displayed his wonderful courage by fiding up in the direction of the house from which the explosion came.

After the first emotion had passed, the cortege continued its route amid shouts of joy for the preservation of the King's life, and threats of vengeance against the assassins. The bodies of the slain, and the persons who are wounded, were immediately carried to the Cafe Sine opposite, where medical assistance was afforded to such as were still alive. Smoke was seen to issue from the third story of the house No. 50, on the Boulevard du Temple, of which the ground and first floor were occupied by a wine dealer, named Parault. Each story consisted of one chamber, which is lighted by a single window in front. The house was immediately surrounded, and all the persons found in it arrested; the room in which the machine had been constructed is very small, being six feet and a half by seven feet.

The machine was made with great skill, of wood, with iron braces, and extremely solid. Two uprights supported two cross bars of wood, placed parallel to the window, and in these were placed 20 gun barrels. The front cross bar placed at about a foot from the window was rather lower than that behind, so that the balls might reach the body of a man on horseback in the middle of the Boulevard. The charge was so heavy, that five out of the twenty-five barrels had burst, notwithstanding they were very substantial and new. The assassin was immediately taken into custody. About three months ago he hired the rooms of the second and third stories of M. Dallemagne, the proprietor.—He gave his name Girard, a mechanic, and appeared to be about 24 years of age. His room has a window in front and another behind, and he had taken the precaution to fasten a rope to the latter, to assist him in making his escape. By the bursting of some of the barrels at the moment of the explosion, the assassin was wounded in the forehead, the neck, and the lip. Notwithstanding his wounds, he rushed out at the window. Some police officers having ran into the inner court, and seeing Girard slipping down the rope, one of them exclaimed, "Ah wretch, we have you." Girard, who was at the moment at the height of a wall, threw himself over it into an adjoining yard, and there was apprehended.

The Minister of the Interior, the Prefect of the Police, and several magistrates went to the house, and in the assassin's chamber they found the remains of the infernal machine still smoking—a straw bed, and a fire lighted. A delay of half a second perhaps in the explosion saved the life of the King. The cortege advanced in the following order:—The King, the Prince de Joinville, the Duke of Orleans, the Duke de Nemours, Marshal Lobau and Marshal Mortier. All those in the cortege who were wounded were nearly all on the same line as Marshal Mortier. The news of the attempt was rapidly propagated through the capital, and produced a powerful sensation. General de Rumigny, Aid-de-Camp to the King, set off full gallop to inform the Queen that his majesty and the Prince had escaped the danger, fearing that she might have been seriously alarmed if she had heard of the event from any one that had not witnessed it. In passing along the lines he mentioned to several officers what had occurred, and soon there was not a soldier that remained ignorant of it. As the troops of the line did not extend to the Boulevard du Temple, they were ordered to shift in that direction, that they might be ready to act in case of attempt at disturbance.

At the moment of filing off before the King, the national guards shouted *Vive le Roi!* which was answered by the troops of the line. The guards of the 8th legion, which had lost some of its officers and men, added cries of *A bas les assassins!* The King returned to the Tuilleries about 5 o'clock, evidently deeply affected by the scene he had witnessed. During the whole of the afternoon and evening, crowds flocked out of curiosity to the melancholy spot, in consequence of which a strong detachment of Municipal Guards was stationed there to keep the peace. The following are the persons whose lives have been ascertained to have been sacrificed: Marshal the Duke Treviso struck in the heart by a ball; General de Lachasse de Terigny, struck on the forehead by a ball; Captain Villate, aide-de-camp to Marshal Maison; Lieut. Colonel

Riussac, of the 8th Legion, struck by three balls; Messrs. Prudhomme, Richard, Leger, and Bennet, Grethadiers of the 8th Legion; a Colonel in the army, two citizens, a woman and a child, whose names we were unable to learn.

Galignani's Messenger of the 30th says—The number of victims is much more considerable than was at first believed. Several persons wounded were immediately taken to their own homes, and therefore were not included in the list before published. The number of killed and wounded is said to be 34, including sixteen who died immediately, or subsequently perished from their wounds. Among them was M. Labronate, aged 70 a member of the Legion of Honor, one of the oldest receivers of taxes of Paris. His wounds are very serious, but hopes are entertained that his life may be saved.—Out of eight persons carried to the Hospital of St. Louis, four have undergone amputation.

At the moment the explosion took place, the king had inclined slightly on one side to receive a petition. The Duke de Broglie received a bullet through the collar of his coat.

In Paris, on the 28th, a grand dinner was given at the Tuilleries, at which all the ambassadors and foreign ministers were present. At dinner and throughout the evening, the King displayed the utmost calmness. He frequently expressed in affecting terms his regret at the death of Marshal Mortier and the other victims of the day.

The Moniteur also contains a royal proclamation and ordonnance to the following effect:—"The fetes for the celebration of the anniversary of July, 1830, shall not be continued. A solemn funeral service shall be performed in honor of the victims of the attempt of this day.

The Government has decided that one funeral procession shall be formed of all the victims of Tuesday, instead of taking place separately. The Chamber of Peers had determined to go into mourning for five days from that of the funerals.

Girard, the assassin, as stated in the *Paris Messenger*, was employed as a dealer in second-hand articles of all kinds, and more particularly engaged in cleaning and repairing fire-arms, and is a very able and skilful workman. He was known among his companions to entertain legitimist opinions, and it was even believed that he received a pension from the Dutchess of Angoulême. He is 29 years of age. Notwithstanding the serious nature of his wounds, he is expected to recover, and is now able to converse. Being questioned as to his motives for committing such a crime, and urged to declare whether he had any accomplice, he fully admitted his guilt, and said he knew his fate was inevitable; but as to his motives, he confines himself to saying that he disliked the king, and further declared, that were he even put to the torture he could not name his accomplice, for in fact and in truth, he had none. Nevertheless, a woman who resides behind the house, has deposed, that an instant after the explosion, she saw two men, both wounded, making their escape. In the room of Girard, two white hats of different sizes were found, which would indicate that at least two parties were cognizant to the construction of the murderous engine. Upwards of one hundred arrests, it is stated, have been made.

The news of the attempt to assassinate the King of France had reached England by Telegraph, and caused considerable sensation.

**MARSHAL MORTIER, DUKE DE TREVISO.**—Marshal Mortier, Duke de Treviso, whose death is reported to have occurred on Tuesday by the bursting of a machine infernale, directed against the life of King Louis Philippe, was born in 1768, consequently he was in his 68th year. He was the son of a merchant, who represented the *tierrat* of Cambresis at the States-General, in 1789. The Marshal was originally brought up in his father's profession, and quitted his station as clerk in a mercantile counting-house at Dunkirk in 1791 to serve in the first battalion of Volunteers of the Department of the north, in which he was at once received with the rank of Captain. Having distinguished himself on various occasions, he was made an Adjutant-General in 1793. His first command as a general officer was at the attack of the fortress of St. Pierre. In 1796 he had the command of the advanced guard of the Army of the Sambre-et-Meuse, then under the orders of General Lefevre. On the 31st of May of the same year, he attacked the Austrians, defeated them, and drove them beyond the Archer. During the whole of the war which was closed by the treaty of

Campo-Formio, we find General Mortier actively engaged, and invariably successful in every enterprise with which he was intrusted by his superiors in command. In the campaign of 1799 he had again the command of the advance guard. His services in that station were, in a great measure, conducive to the success of the French arms, and to the high opinion that Napoleon conceived of his military talents. It was General Mortier whom Napoleon sent, in 1803, at the head of his first expedition to Hanover. The whole of the military operations were, on the part of the French army, directed by General Mortier, and the result was the memorable Convention of Suhlingen, by which the Electorate of Hanover was placed in the hands of the French. On his return to Paris he was appointed to the command of the artillery of the Guard, and in 1804 he was raised, with other officers of superior merit, to the rank of a Marshal, and decorated with the Grand Cross of the newly instituted order of the Legion of Honor. In the campaigns of 1805 and 1806, General Mortier was at the head of one of the divisions of the grand army, commanded in chief by Napoleon in person. The greatest feat of arms ever achieved by any French troops fell during this war to the lot of a corps of 4,000, commanded by Marshal Mortier. Having fallen in with the whole of the Russian army, led by Kutusoff, and forced to accept battle or lay down his arms, Mortier fought with a valor and superiority of tactics which allowed sufficient time for considerable reinforcements to come to his aid. This affair gave great celebrity to Mortier's name throughout the French army and in France. His fellow-citizens at Cambrai wished to raise a public monument in that city in memory of his action with Kutusoff, but Mortier positively refused to allow it. It was Marshal Mortier who captured Ham-burgh at the close of 1806. On that occasion he displayed a rancorous hostility against every thing that was English, which greatly surprised all who had any knowledge of his early life. In his younger days he had lived a good deal in Scotland, and the counting-house in Dunkirk where he received his commercial education, was that of an English merchant. His intimacy and intercourse with the natives of this country, of which he spoke the language fluently, had been such, that few would believe it was in pursuance of orders issued from himself that the whole of the British residents in Ham-burgh were thrown into prison, and every particle of their property confiscated. In 1806, he was raised to the imperial Dukedom of Treviso, receiving at the same time a "dotation," attached to the title, of 100,000 francs (4000*l.*) per annum, payable out of Crown domains of Hanover. It is hardly necessary to say that he lost this income at the peace of 1814. Soon after the opening of the Spanish war he was sent to Spain, where he co-operated with several successive Commanders in Chief, and fought the battle of Ocana, which he and his countrymen have claimed as having been won by the corps under his immediate command. Subsequently he accompanied Napoleon to Russia, and it was to him that the hazardous undertaking of blowing up the Kremlin at Moscow was intrusted. He took an active part in the whole of this and the subsequent campaigns under Napoleon, up to the peace. During the earlier part of the reign of Louis XVIII., Marshal Mortier spent his time in Paris, apparently little desirous of figuring in the military or political world. In 1816, however, he was appointed Commandant of the 15th military division, the seat of which is Rouen, and soon after he was elected by his native department of the north Member of the Chamber of Deputies, in which he sat till 1819, when he was raised to the Peerage. In 1834, on the resignation by Marshal Soult of the Presidency of the Council and Ministry of War, the whole Ministry being then disjointed, and, much against the wish of the King, on the eve of dissolution, Marshal Mortier was solicited by the King to accept the offices which Marshal Soult had given up, he being the only individual at that moment with whom, and under whose presidency, the other members of the Soult Administration were willing to remain in office. The Marshal yielded with extreme reluctance to the wishes of the King. He knew that politics were not his element, and soon after, at the Ministerial council table, as well as on the Ministerial benches in the two Legislative Chambers, he felt that he was not in his proper place. The remarks and jokes of the press about his silence in the Chambers, and his inactivity as a Minister, however good naturedly expressed, at length drove the Duke

de Treviso to the positive resolution of withdrawing forever from the Ministerial career. One morning in the early part of February, therefore, he waited on the King, placed his act of resignation in the royal hands, and gave his Majesty to understand that his resolution to withdraw was not to be changed. Mortier is among the few of Napoleon's Generals whose reputation for integrity and private worth has remained unquestioned through life. Though not very popular, owing to a natural stiffness in his manners, not more habitual among, than agreeable to, the French, he was always spoken of with respect, and to the last day of his existence he has enjoyed the undivided esteem of his countrymen.—[Times.]

A disastrous explosion occurred at Greenock on the 24th July, on board the Steamboat Earl Grey—the boiler of which burst, while lying at the wharf, and killed five, and injured more or less twenty-five persons.

**CURIOUS MANUSCRIPT.**—In a list of ancient literary manuscripts, and remarkable manuscripts, recently announced for sale by the Messrs. South-erby, of London, is one with the following title:

"A Letter from the Earl of Bath to Lord Norreys, dated April 16, 1681—being 'A proposal for the sale of the Province of New Jersey, a country almost as large as England, belonging to the late George Carteret, for the small sum of between 5000 and 6000 pounds.'"

Thus it appears that one hundred and fifty-four years ago, the whole State of New Jersey was offered for sale for the sum of about twenty-five thousand dollars.—[Gazette.]

**THE GRAND DUKE CONSTANTINE AND HIS WIFE.**—"Three or four times a week I received commands to attend his levee, and not unfrequently to breakfast—a meal which he commonly took at about 11 o'clock in the day. On these occasions he seemed to take considerable pleasure in all I could tell him of England and its modes and customs—its army, its capital, and its domestic and commercial resources. If on some of these subjects I confessed my ignorance, he would eye me with a doubting and suspicious glance, urge me again and again on the same point, as if he thought I was unwilling to explain, or expressly reserved that of which I confess I was utterly ignorant; or he would dash up in a towering passion, break into some intemperate expressions, and declare that I ought to be ashamed of myself not to be acquainted with statistics, which even foreigners knew well. In these sudden and unforeseen excesses of passion, he was with difficulty pacified—a task upon which I never dared venture—I could only look on and listen in silence; but if his elegant and amiable Princess was present, as was not unfrequently the case, her graceful tenderness and endearments calmed down the storm: she petted him like a froward child, and with a doubting pause or a half-muttered growl his good humor returned. This charming and accomplished creature was his wife, by one of those left-handed marriages so common and well understood among the German Princes, and it was always a matter of surprise to me by what strange freak of destiny a being so mild and gentle in manners, so graceful, so tender and amiable in all the acts and movements of her life, could have been linked to such a monster: and what seems stranger still, she loved him, and thence, perhaps, the secret of her influence. I have seen him often playing with her long ringlets, or fondling in his great paw the prettiest and whitest hand in the world, or kissing his hand to her at a window with an air that actually approached to tenderness. She, indeed, was the only person who possessed any real influence over his mind, and her gentle ways could soothe the wild beast in his angriest moods: she would follow him as he stamped about the room: she expostulated, she wheedled, she caressed, she would try with a tear in her eye to make him laugh; and it would seem that, almost in spite of himself, the smile she sought so anxiously came at her bidding: he would look into her eyes, kiss her little hand, and seat himself again without another allusion to the cause of the explosion. He seemed almost to encourage her interference, and he played with her as a child would with a doll; but she was a plaything with which he never quarrelled. He seemed proud, too, of her mental acquirements, and he delighted in the display of her accomplishments. Indeed, I at one time attributed it as a principal

cause why I was so often an invited guest at the Belvidere, that it afforded her the opportunity of speaking English—an accomplishment in which she excelled: she possessed considerable fluency, and that least possible smack of foreign accent which could not be otherwise than pleasing on the lips of a pretty woman. Constantine took great pleasure in setting us talking in that language—he rubbed his hands, and listened with evident gratification as she prattled away in a tongue which he did not understand, and continued repeatedly to express his pleasure and satisfaction. His tenderness for this mild and gentle being was at least a redeeming point in his character, and his attachment was repaid on her part by the most devoted and entire affection. Poor thing! his death broke the slight cord which attached her to life; whether it was that her whole soul, her existence, was wrapped up in him who had raised her from comparative obscurity almost to a throne, or whether it was that she missed the being who, however harsh to others, was always, after his fashion, kind to her—whom she had been long accustomed to cajole, to fondle, to guide, to moderate—the link was severed—her gentle heart broke under the shock, and, after hardly two months of a painful widowhood, she sunk into the grave which had received her husband.—[Monthly Magazine.]

A young officer of the French navy, who was a long time stationed at Senegal, tamed a young hyena, which became attached to him in a degree very unusual for this ferocious animal. On his return to Brest, the Maritime Prefect induced him to send his favorite as a present to the Garden of Plants. After a lapse of time the officer came to Paris, and naturally went to visit the menagerie. In the mean time, the animal had resumed all its native ferocity, and became violent the moment any of the spectators even looked steadfastly at it. At the first sight, however, of his former master, the hyena recognised him, showed the utmost satisfaction, mildly moving his head and wagging his tail, as if inviting the officer to caress him. The officer, to the terror of the spectator, approached the animal, stroked his back, and even put his hand into the creature's mouth, but still greater was their astonishment when they saw the beast return his caresses by gently licking his hands.

The *Diario di Roma* mentions the publication at Rome of a small pamphlet entitled, *The Pharaohs in the times of Abraham, Joseph and Moses, as known by the Scriptures and the Monuments of the Egyptians*. It fixes, by accurate calculations, the commencement of the kingdom of Egypt—the Pharaoh by whom Sarah was taken from Abraham, when he came into that country—which of them brought up Joseph, the son of Jacob, and made him viceroy—which of them it was whose daughter saved Moses—and, finally, the Pharaoh who was drowned in the Red Sea.

"Mr. Thomas Gill, son of Mr. Gill, of the French Horn Inn, Sarum, was married on the 28th June, at Salisbury, by the Rev. Dr. Hawes, to a Miss Angell, late of Newfoundland, by which marriage he will shortly come into possession of a number of estates and money, amounting in value to 1,000,000*l.*, left by a Mr. Angell, who died some 60 years since. The Chrois estate, near Lambeth, forms part of the landed property, and to possess which he must bear the name and arms of the Angell family. He is at present the mail-cart man on the line of road from Warminster to Sarum."—[Devizes Gazette.]

The *Académie des Inscriptions et Belles Lettres* has elected M. de Hammer, author of the *History of the Ottoman Empire*, and many other works, one of its foreign Associates, in the room of the late Baron William de Humboldt.

In making a new sluice to the citadel of Calais, an ancient vessel, forty-five feet in length, twelve in breadth, and eight in depth, was discovered in the ground; strongly built, though its measurement does not exceed eighty tons, and has evidently never been covered with a deck. Coins were found in it with the date of 1219; and, as it lay twelve feet below the foundations of the inner wall of the fortifications erected by the Count de Boulogne, it is to be presumed that the vessel was not discovered at that period. It cannot be ascertained whether it was ever at sea, but there is reason to believe it was erected before Calais was made a regular port, and when the sea ran far up the present land.—[Paris paper.]

A new tulip, reared by M. Patix, a gardener at Ghent, and which the Society of Florists of the town has named the "Citadel of Antwerp," has been purchased by Mr. Vanderninck, a horticulturist of Amsterdam, who was formerly a captain in the Dutch navy, at the price of 16,000 francs.—[Paris paper.]

[From Kirby's Bridge-water Treatise.]

**DULNESS OF A VEGETABLE WORLD.**—Unpeopled by animals, the verdant earth in all its primitive and untarnished beauty, though inlaid with flowers, exhibiting in endless variety every mixture and shade of color that can glad the sight—though fanned by gales breathing Sabean odors to gratify the scent—though tempting the appetite by delicious fruits of every flavor—still would be a scene without the breath of life. No motion would be seen but of the passing clouds, of the fluctuating waters, and the waving boughs; no voice heard but of the elements.

Was a single pair placed in this paradise, though at first it would seem that there was gratification for every sense, and joy would possess the heart, and admiration fill the soul with pleasure,—yet after the novelty of the spectacle had ceased, and the effect of its first impression was obliterated, a void would soon be felt, something more would seem wanting to animate the otherwise lovely scene; a longing would arise in the mind for some beings, varying in form and magnitude, furnished with organs that would enable them to traverse and enliven the lower regions of the atmosphere, others that might course over the earth's surface, and others that could win their easy way through its waters, so that all by their numbers and the variety of their motions, might exhibit a striking and interesting contrast to the fixed and unconscious vitality of the vegetable kingdom.

**ADVANTAGES OF MIGRATIONS OF ANIMALS.**—If we give this subject of the migration of animals due consideration, and reflect what would be the consequence if no animals ever changed their quarters, we shall find abundant reason for thankfulness to the Almighty Father of the Universe, for the care he has taken of his whole family, and of his creature man in particular, consulting not only his sustentation and the gratification of his palate by multiplying and varying his food, but also that of his other senses, by the beauty, motions, and music of the animals that are his summer or winter visitors: did the nightingale forsake our groves, the swallow our houses and gardens, the cod-fish, mackerel, salmon, and herring our seas, and all the other animals that occasionally visit us, their several haunts, how vast would be the abstraction from the pleasure and comfort of our lives!

By means of these migrations, the profits and enjoyments derivable from the animal creation are also more equally divided, at one season visiting the South, and enlivening their winter, and at another adding to the vernal and summer delights of the inhabitants of the less genial regions of the North, and making up to him for the privations of winter. Had the Creator so willed, all these animals might have been organized so as not to require a warmer or a colder climate for the breeding or rearing of their young; but his will was, that some of his best gifts should thus oscillate, as it were, between two points, that the benefit they conferred might be more widely distributed, and not become the sole property of the inhabitants of one climate;—thus the swallow gladdens the sight both of the Briton and the African; and the herring visits the coasts, and the salmon the rivers, of every region of the globe. What can more strongly mark the design, and the intention of an all-powerful, all-wise, and beneficent Being, than that such a variety of animals should be so organized and circumstanced as to be directed annually, by some pressing want, to seek distant climates, and, after a certain period, to return again to their former quarters; and that this instinct should be productive of so much good to mankind, and, at the same time be necessary, under its present circumstances, for the preservation or propagation of the species of these several animals?

**THE POETRY OF LIFE.**—We hear a great deal of the philosophy of life—the poetry of life is equally real, and far more generally diffused. It is that spirit which mingles itself with all our hopes affections, sorrows, and even death, and beautifies them all. It mingles itself with the ambition of aspirants in every honorable track—with the emotions of the lover, with the ardor of the hero, till it

covers the battle field pit from his eyes, and shows him only the halo of glory—with the patriotism of the righteous statesman—with all our social attachments and intercourse, and spreads the roses of heaven on the beaten path of our daily life. No human speculation, no human pursuit, no human feeling, which is not utterly selfish and base, but draws fire and force from this spirit—and is borne by its elating influence towards its legitimate end. It is impossible to point out any nation that has become great, or even successful for a time, without it. Of the ancient nations we need not speak—in all, of which we know anything but the barest facts, poetry, and the intense desire of glory, which cannot exist totally distinct from poetical feeling, were found. From some of them what have we not received! The very Saracens, when, under Mahomet, they suddenly overflowed Asia, Africa, and part of Europe, were set on fire by the poetic charms of his new paradise:—the Tuetons, that extinguished the last sparks of the Roman empire, and laid the foundations of the present European kingdoms, were not led hither merely for food—it was Valhalla, and the poetic legends of their Scalds, that armed and animated them. We cannot take away poetry from life, without reducing it to the level of animal stupidity. In our days, stupendous events have passed on the face of the civilized world, and equally extraordinary has been the development of poetic power. A host of great names will be left to posterity, and with them a host of new impulses that will fill futurity with increase of light and happiness; and as Christianity becomes better understood, as our natures become better understood, as the spirit of love begins to predominate over the spirit of selfishness, the true poetry of life, and its power, shall be more and more acknowledged. Men will feel that in aspiring after true honor—in desiring to become benefactors of men—to spread knowledge and intellectual beauty, they are but giving exercise to the divine spirit of poetry which is sent down from heaven to warm and embellish every human heart, though often unseen and unacknowledged; and they will work in the spirit of love and in its enjoyment.—[A Day Dream at Tintagel, by W. Howitt.]

What is there in a name?—The London Literary Gazette, in a complimentary notice of *Outre-Mer*, by Professor Longfellow, of Dartmouth College in New Hampshire, ascribes the work to Mr. Longbody!

#### SUMMARY.

We learn from the Arkansas Gazette, that the rumored attack on Major Mason's command by the Camanche and Pawnee Indians was erroneous. The report originated with a party of Osages. The chiefs of the supposed hostile band have since visited Major Mason's camp and convinced him that they had no hostile resolutions towards his detachment.

The same paper states that it was sickly at Fort Gibson at the period of the last dates from that post. Governor Stokes one of the Commissioners to treat with the Indians, was not able to sit up, but he intended to set out, or attempt it, on the 5th of August, for the place of rendezvous, (Major Mason's camp,) 160 miles distant from the post of Gibson. A large detachment of infantry, was to accompany Governor Stokes to the treaty ground.

An extra Official Gazette was published at Quebec on Tuesday, containing a Proclamation of His Excellency the Right Hon. the Earl of Gosford, announcing his appointment as Captain General and Governor-in-Chief in and over the Provinces of Upper and Lower Canada respectively; and commanding His Majesty's Officers and Ministers in Lower Canada to continue in the due execution of their respective offices; and the Commission of His Majesty, appointing the Right Hon. the Earl of Gosford, the Right Hon. Sir Charles Edward Groy, and Sir George Gipps, Commissioners for the investigation of all grievances affecting His Majesty's subjects in the Province of Lower Canada, in what relates to the Government of the Province.—[Montreal Gaz.]

A right whale was captured in the beginning of

last month, on Watt's Shoal, (off the mouth of the Potomac,) by Captain Jonah Porter, residing near the spot, who, after getting him fast aground, pierced him with iron run-roads, instead of a harpoon. The Norfolk Herald says "the monster was 58 feet in length, and yielded, notwithstanding Capt. Parker's limited knowledge of the process of procuring it, eighteen barrels of oil, 14 of which were sent to Fredericksburg and sold."

**SOUTH FERRY.**—We understand that the lease for this ferry has been executed. Our City Council and the Company have taken the most prompt and efficient measures to put the ferry in complete operation very soon. The grading of Atlantic st. to Parmentier's Garden has been completed, and the paving will be completed this fall.

The guns of the battery aimed at the King of the French which did not go off as intended, were the first five, pointing towards the head of the column. By this remarkable circumstance the life of the King was preserved. After the affray the King and the Duke of Orleans were both found to have wounds upon them, but they were supposed to have been made in the confusion which ensued upon the discharge.—[Journal of Commerce.]

**APPOINTMENT BY THE PRESIDENT.**—Robert J. Hackley, to be Register of the Land Office for the district of lands subject to sale at Tallahassee, in the Territory of Florida, vice George W. Ward, deceased.—[Globe.]

[From the Globe of Wednesday.]

The following arrangements, we are informed have been entered into voluntarily by the Deposit Banks, as far as named, for the redemption of their notes in New York or Philadelphia, and the receipt of each other's notes, viz:

**BANK OF BURLINGTON, Burlington, Vermont.**—This Bank redeems its notes of all denominations of five dollars and upwards, *unlimitedly*, at the Merchants' Bank in the city of New York. It also receives on deposit the notes of such Banks, as are at par, either in New York, Philadelphia, or Boston.

**MECHANICS' AND FARMERS' BANK, Albany.**—This Bank redeems all its notes of the denominations of fifty dollars and upwards, *unlimitedly*, at the Merchants' Bank in the City of New York. It also receives the notes of all Banks which are at par in New York or Philadelphia.

**BANK OF AMERICA, New York.**—This Bank will receive the notes of all the Deposit Banks situated north and east of that city, of the denominations of fifty dollars and upwards, on deposit, from Deposit Banks, which they may have received from the Receivers of sales of the Public Lands.

**MECHANICS' BANK, New York.**—This Bank will receive the notes of the two Deposit Banks in Boston, (the Commonwealth and Merchants') they having arranged with this Bank to redeem the same, of all denominations of five dollars and upwards.

**GIRARD BANK, Philadelphia.**—This Bank will receive from all the Deposit Banks, the notes of any and all the Deposit Banks north and east of Philadelphia, which they may receive from the Public Land Receivers, of the denominations of fifty dollars and upwards.

**UNION BANK OF MARYLAND, Baltimore.**—This Bank redeems its notes *unlimitedly*, in New York, at the Merchants' Bank; and in Philadelphia, at the Philadelphia Bank; and it receives on deposit and in payment of all dues, the notes of all good Banks which are redeemed in those cities.

**BANK OF THE METROPOLIS, Washington.**—This Bank redeems its notes, *unlimitedly*, in Philadelphia, at the Girard Bank; and in New York, at the Bank of America, Mechanics' Bank and the Manhattan Company. It receives on deposit the notes of all such Banks as are at par in either of those cities.

**BANK OF VIRGINIA, Richmond.**—This Bank redeems its notes, *unlimitedly*, in Philadelphia, at the Girard Bank, and the Farmers' and Mechanics' Bank; and in New York, at the Mechanics' Bank and Manhattan Company. It receives the notes of all Banks, above the denomination of ten dollars, which redeem their notes in either of the above cities.

**BANK OF AUGUSTA, Augusta.**—This Bank redeems, at the Bank of America, in New York, such of its notes as may be received by the Receivers, of proceeds of sales of Public Lands.

**UNION BANK OF LOUISIANA, New Orleans.**—This Bank will redeem, at the Merchants' Bank in New York, all its notes which may be received by Deposit Banks, in payments on account of the Government. It will receive on deposit, from the Receivers of Public Lands, the notes of all such Deposit Banks as cause them to be redeemed in New York or Philadelphia.

**COMMERCIAL BANK OF NEW ORLEANS, New Orleans.**—This Bank will redeem, at the Bank of America, in New York, such of its notes as may be received by deposit Banks for all payments made on account of Government. It will receive on deposit from the Receivers of Public Lands, the notes of all such Deposit Banks as redeem the same in New York or Philadelphia.

**PLANTERS' BANK, Natchez.**—This Bank, has in no instance since it became a selected Bank, refused to receive from a Public Receiver, a note of any one of the Deposit Banks. It will continue to receive on deposit, from the Public Receivers, the notes of each and all the Deposit Banks, without regard to their location.

**UNION BANK, Nashville.**—This Bank issues but few notes which are not made payable upon their face, either at Philadelphia or New Orleans. It will receive in payment of all dues to the Government, the notes of all Deposit and other Banks, which redeem the same, either New York or Philadelphia.

**COMMERCIAL BANK, Cincinnati.**—This Bank will redeem at the Girard Bank, in Philadelphia, all its notes of the denomination of fifty dollars and upwards, which may be received by any Deposit Bank, to be placed to the credit of the United States. It will receive on deposit, from Public Receivers, the notes of all such deposits and other good Banks, at Cincinnati, and its agency, at St. Louis, as redeem the same in New-York or Philadelphia.

**CLINTON BANK, Columbus.**—This bank will redeem, at the Phoenix Bank, in New-York, all its notes of the denominations of fifty dollars and upwards, as may be received by any Deposit Bank from the Public Receivers. It will receive on deposit, from the Public Receivers, the notes of all such Deposits and other good Banks as redeem the same either in New-York or Philadelphia.

**STATE BANK OF INDIANA, Indianapolis.** This Bank will redeem, at the City Bank in New-York, any of its notes of the denomination of fifty dollars and upwards, which may be received by any Deposit Bank, from the Public Receivers. It will receive on deposit, from the Public Receivers, the notes of all such Deposit and other good Banks which redeem the same either in New-York or Philadelphia.

**STATE BANK OF INDIANA, Richmond Branch.**—This Bank will redeem, at the Bank of North America, in Philadelphia, and the Merchants' Bank in New York, all such notes of the denominations of fifty dollars and upwards, as may be received by any Deposit Bank from the Public Receivers. It will receive from the Public Receivers the notes of all such Deposit Banks as redeem the same either in New York or Philadelphia.

**BANK OF MICHIGAN, Detroit.**—This Bank will redeem, in the City of New York, through their agents, Messrs. John Ward & Co., all such of its notes of the denominations of \$50 and upwards, as may be received by any Deposit Bank from the Public Receivers. It will receive from the Public Receivers the notes of all such Deposits and other good Banks as redeem the same either in New York or Philadelphia.

**FARMERS' AND MERCHANTS' BANK, Detroit.**—This Bank will redeem, at the Bank of America, in New York, all such of its notes of the denominations of fifty dollars and upwards, as may be received by any Deposit Bank from the Public Receivers. It will receive from the Public Receivers the notes of all good Banks north of the Potomac and Ohio rivers, and of such southern Banks as redeem the same either in New York or Philadelphia, of the denominations of twenty dollars and upwards.

**MERCHANTS' AND MANUFACTURERS' BANK, Philadelphia.**—This Bank will redeem, *unlimitedly*, such of its notes as may be received by any Deposit Bank, from the Public Receivers, at the Commercial Bank in Philadelphia. It will receive on deposit, on public account, the notes of all such Deposits on other good Banks as redeem the same in New York or Philadelphia, of the denominations of twenty dollars and upwards.

[From the Chicago American of August 22.]

**THE INDIANS.**—Our town is now crowded with Indians, who have come to receive the last payment stipulated in the Treaty of 1833. They present a singularly interesting appearance, and to eastern emigrants more especially, are objects of great curiosity. They display, in their dress and manners, the wild fancy, uncultivated taste, and native simplicity of the Indian character. Their faces and bodies are painted with grotesque figures of divers colors; gaudy trappings of silver hang upon their breasts or girt their arms; beads and other jewels hang from their ears, or noses, or load their necks; quills and feathers, and heads of birds, are woven into their hair; scarlet bands, richly interwoven with beads, from which hang bells and tassels, girt their legs. They traverse the streets on their ponies, caparisoned with scarlet cloth, with feathers and bells, or on foot with spears and daggers, pipes and tomahawks, &c. &c., entertaining the citizens with songs and dances. We suppose this is the last general visit we shall receive from them. The exploring party sent out by the Government, accompanied by a deputation of Indians, to visit the new country which was given them in exchange for the lands in this region, and to which they will probably be removed in the coming fall, have not yet returned, but will soon be here. The removal of the miserable remnants of these once powerful tribes, is not only the most advantageous to the people of the United States, but also to the Indians themselves, who are now weakened in power, diminished in number, enfeebled in constitution, and depraved in morals, by their proximity to the white people. Those tribes now west of the Lakes, were the fierce nations which inhabited the peninsula of Michigan. The warlike deeds and shrewd stratagems of Pontiac, the great Ottawa chief, are a part of the history of this country. His assassination by the Illinois Indians, was the cause of the introduction of the Ottawas & Pottawatomies into this region, who pursued the murderers of Pontiac almost to utter extermination. The destruction of a great number of them upon "Starved Rock" at Utica, is an account well known to all. The Illinois Indians were pursued until they took refuge upon the top of this Rock, which is 150 feet high, standing on the banks of the Illinois river, and were besieged by their fierce pursuers, until they were *starved to death*, and for many years after, their uncoffined bones whitened the summit of the rock. But these powerful tribes are following the Illinois, the Peorias, the Kickapoos, the Kaskaskias, &c. who now scarcely retain their identity as separate tribes. A removal beyond the Mississippi is doubtless the true policy for them.—They will not be reclaimed from the Indian customs so long as there are hunting grounds unobdured.—The march of civilization and improvement towards the West, brings blasting and mildew upon them. They do not acquire the knowledge of the white men but adopt their vices without imitating their virtues. While we triumph in our own prosperity, and look with warm hopes to the future, we have the melancholy example before our eyes of the increased degradation and destruction of a mighty people. We know that *our success is their fall*.—And however ardently we may desire their improvement, we find that the Indian character has in the main thwarted all efforts for its elevation.—They possess a propensity for savage life which will not harmonize with the existence of civil institutions; and though many efforts have been made to Christianize them, by teaching them the truth of Christianity, yet these labors cannot be said to be generally successful. And judging from the history of the last three hundred years, we may suppose they will continue to retire before the progress of enlightened improvement, to the last thicket, and when worsted there—will find their grave.

**LIBEL.**—Ira C. Paine, of Painesville, Ohio, has recovered a verdict of \$52.50 against Eber S Howe, publisher of the Painesville Telegraph, for printing "his name in *small italics*" as Secretary of a political meeting, in connection with remarks reflecting upon his character.—[Buffalo Adv.]

The question which of late has been often asked us, we can now answer, viz: the large new building now being put upon Ellis' Island, is a magazine, in which the powder required for our naval operations will be stored. It is a spacious depot, and its location is so remote from a dense population, that if it should ever explode, few, if any lives would be lost.—[Gazette.]

Mr. Clayton, the Western aeronaut, narrowly escaped a sudden and violent end, during a balloon ascension which he made on the 21st August at Lexington, Ky. He had risen to an elevation of about two miles, when the perilous occurrence alluded to took place. We copy his own account of it.

At 23 minutes after 5, when at an altitude of two miles, I discovered that the gas had completely filled the balloon, and that the neck had become entangled between the cords by which I was suspended, preventing the surplus gas from escaping, and confining the valve cord so that I could not open the valve.

I immediately busied myself in liberating the valve cord, and while in the act of doing this, the neck and cord were snatched with violence from me; the upper portion of the balloon burst with a tremendous noise, and I and the whole fabric fell two or three hundred feet, with the velocity of a stone. The rapid descent was then a little checked; and now the most critical moment of my life was at hand—a moment that required calmness, presence of mind and activity, for an awful scene presented itself. The lower part of the balloon, by the violent resistance of the atmosphere, in descending, had been pressed against the surface of the net-work, and formed into a parachute, of about twenty-five feet in diameter; but through the centre of this imperfect parachute I could behold the naked valve, the small meshes of the net, and a great portion of the silk on each side, which formed the resisting surface, hung in ribbons, dashing from side to side, and producing a noise like that of shattered sails of a ship in a tempest. This hurricane noise was not produced by the rapid descent alone, but by the violent oscillatory and rotary motion of the parachute. At one moment I was almost in a horizontal line with the parachute, and then I was dashed through the air to a level on the opposite side; thus describing an arc of nearly a semi-circle, the radius of which was about fifty feet; and at the same time I and my car were whirling with sickening velocity.—While in this situation I succeeded in dashing overboard all my bags of ballast, which weighed about 80 lbs.

In four minutes I descended about a mile, and reached a region of dense clouds. At this time I untied the upper end of my cable and held it in my hands, threw over my anchor and allowed it to swing at the full length of the rope (150 feet); it was thrown at every vibration far above the level of my car.

On passing beneath the cloud, I saw the town of Athens a little to the south west of me.—In five minutes more I reached the ground with a pretty severe shock sustaining no injury worth mentioning. The whole balloon or parachute, was instantly flat on the ground, a mass of ribbands. At few dark faces (negroes) appeared at a short distance from me, with outstretched hands—screaming—frightened to death at the huge machine that came whirling over their heads, and still more frightened when they saw me spring out of it.

**GENERAL LAND OFFICE.**—On Tuesday Ethan Allen Brown, of Ohio, was duly installed as Commissioner of the General Land Office, vice Elijah Hayward, resigned, who, we understand, returns to the West.—[Nat. Int.]

**A STRANGE STORY—AND AS TRUE AS STRANGE.**—We were told the following singular story by a planter of high respectability, on Friday last.—Early in the season he purchased work horses for his plantation, and now, at noon, they feed in the open air. The poultry, as is customary, assembled where the horses are fed. A few days ago, hens with their broods of chickens approached the troughs where the horses were eating, when it was observed that one of the horses left his food, and by moving his head near the ground, collected the young chickens in a huddle, and grabbed a mouthful of the brood, which he actually ate. Now did he stop at that, but before relief could be afforded, he got a second mouthful which he also ate. The gentleman added that his slaves have lost many of their chickens, and the horse is accused of having eaten them. This must be a Kentucky horse—for the Kentuckians are said to have half horse and half alligator, and the one we speak of appears to have much of the latter animal in his composition, with a little touch of the snapping turtle.—[Louisville Jour.]

## METEOROLOGICAL TABLE.

For the months of June and July, 1835—kept at  
Avoyles Ferry, Red River, Lou., (Lat. 31° 10' N.,  
Long. 91° 59' W. nearly,) by P. G. VOORHIES.—  
[Communicated for the American Railroad Journal.]

JUNE.

Red river rose this month, 1 foot 4 inches—and is  
below high water mark, 6 feet 6 inches.

JULY.

Red river rose this month, 6 inches—below high  
water mark, 6 feet.

## PARTNER WANTED:

Wanted, a partner in an extensive Printing Estab-  
lishment. No one need apply who is not a thorough-  
bred printer, competent to superintend and direct an  
office in which upwards of 30 persons are employed,  
and able to furnish \$3000 cash capital. The best of  
references will be given and required. Letters, with  
real name, may be addressed to P. F. P., Post Office,  
New-York, postage paid, and they will be promptly  
attended to. May-17

## TO TUNNEL MINERS, DRILLERS, &amp;c.

Wanted, immediately, 40 Tunnel Miners, (Cornish Mi-  
ners will be preferred,) 80 Drillers, 50 Laborers, and two  
experienced Mine Blacksmiths, on the New York and  
Hartford Railroad, about five miles from the City. Liberal  
wages will be given, and cash payments made every fort-  
night. Apply at Mr. FOWLER'S, 51 John's Hall, Frank-  
furt street, New-York.

JOHN RUTTER, Contractor.

30- The Albany Argus, Philadelphia U. S. Gazette and  
Pennsylvania, will please copy this, and send their bills to  
the Railroad Company, 14 Wall street, New-York. 23-47

TO CONTRACTORS FOR EXCAVATION AND  
MASONRY.

PROPOSALS will be received at the Office of the Phila-  
delphia and Reading Rail Road Company, in Phila-  
delphia, on the 19th and 20th days of October next, for the  
Grading and Masonry, of about sixteen miles of the Rail  
Road between Pottsgrove and Norristown.

In this distance, a large amount of heavy work, deserv-  
ing the attention of skilful and competent Contractors, is to  
be let. The Jobs of most magnitude, are a Tunnel 600 yards  
long, and a Bridge across the Schuylkill, near Phoenix-  
ville.

Plans and profiles of the line, and drawings of the differ-  
ent constructions on it will be exhibited, and all other infor-  
mation in relation to it will be afforded, on application at the  
Engineer's Office, at Pottsgrove, for ten days previous to  
the letting. MONROE ROBINSON, C. E.  
Philadelphia, Sept. 2, 1835. 23 SawtOis

## AMES' CELEBRATED SHOVELS,

## SPADES, &amp;c.

500 dozens Ames' back-strap and plain Shovels,  
75 do do round-pointed do  
150 do do cast steel Shovels and Spades,  
100 do do Socket Shovels and Spades,  
150 do do steel plated Spades.

Together with Pick Axes, Churn Drills, and Crow Bars,  
steel pointed, made from Salisbury refined iron. For sale  
by his Agents,

WITHERELL, AMES &amp; CO.

2 Liberty street, New-York.

BACKUS, AMES &amp; CO.

8 State street, Albany.

24-yf

## RAILROAD IRON WORK,

Of all kinds, made to order by GODWIN, CLARK & CO.,  
Paterson, New-Jersey.

CAR WHEELS, BOXES, AXLES, and CAR SPRINGS, made  
and fitted complete, at short notice, and fair prices.

Orders addressed to them at Paterson, N. J., or 24 Broad  
street, N. Y., will meet with immediate attention.

Paterson, Aug 19, 1835.

34-yf

## RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Eagle  
Air Furnace and Machine Shop, will make to order car  
wheels, chairs and knees, and every other description of  
castings required for railroads. R-1y feb14

## STEPHENSON,

Builder of a superior style of Passenger Cars for Rail-  
roads.

No. 264 Elizabeth street, near Bleeker street,  
New-York.

IF RAILROAD COMPANIES would do well to  
examine these Cars; a specimen of which may be seen  
on that part of the New-York and Harlem Railroad  
now in operation. J36 if

PATENT RAILROAD, SHIP AND BOAT  
SPIKES.

The Troy Iron and Nail Factory keeps constantly  
for sale a very extensive assortment of Wrought Spikes  
and Nails, from 2 to 18 inches, manufactured by the sub-  
scriber's Patent Machinery, which after five years suc-  
cessful operation and now almost universal use in the United  
States (as well as England, where the subscriber ob-  
tained a Patent,) are found superior to any ever offered  
in market.

Railroad Companies may be supplied with Spikes hav-  
ing countersink heads suitable to the holes in iron rails,  
to any amount and on short notice. Almost all the Rail-  
roads now in progress in the United States are fastened  
with Spikes made at the above named factory—for which  
purpose they are found invaluable, as their adhesion is  
more than double any common spikes made by the ham-  
mer.

All orders directed to the Agent, Troy, N. Y., will  
be punctually attended to.

HENRY BURDEN, Agent.

Troy, N. Y. July, 1835.

Spikes are kept for sale, at factory prices, by I.  
& J. Townsend, Albany, and the principal Iron Merchants  
in Albany and Troy; J. I. Brower, 225 Water street, New-  
York; A. M. Jones, Philadelphia; T. Janviers, Balti-  
more; Degrand & Smith, Boston.

F. S.—Railroad Companies would do well to forward  
their orders as early as practicable, as the subscriber is de-  
stirous of extending the manufacturing so as to keep pace  
with the daily increasing demand for his Spikes.  
1/23 Jan

H. BURDEN.

RAILROAD CAR WHEELS AND BOXES  
AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels  
complete at the Jefferson Cotton and Wool Machine  
Factory and Foundry, Paterson, N. J. All orders ad-  
dressed to the subscribers at Paterson, or 80 Wall  
street, New-York, will be promptly attended to.

Also, CAR SPRINGS.

Also, Flange Tires turned complete.

Jas ROGERS, KETCHUM &amp; GROSVENOR

PATENT HAMMERED SHIP, BOAT, AND  
RAILROAD SPIKES.

Railroad Spikes of every description required,  
made at the Albany Spike Factory.

Spikes made at the above Factory are recommended to  
the public as superior to any thing of the kind now in use.  
Ship and Boat Spikes made full size under the head,  
so as not to admit water.

Orders may be addressed to Messrs. ERASTUS COR-  
NING & CO., Albany, or to THOMAS TURNER, at the  
Factory, Troy, N. Y. sept. 13-1y

## RAILWAY IRON.

395 tons of 1 inch by 1/2 inch,	Flat Bars in lengths of
300 do. 1 1/2 do. do.	14 to 18 feet, counter sunk
40 do. 1 1/2 do. do.	holes, ends cut at an angle
300 do. 3 do. do.	of 45 degrees, with spli-
900 do. 2 1/2 do. do.	cing plates and nails to
	suit.

soon expected.  
250 do. of Edge Rails of 36 lbs. per yard, with the re-  
quisite chairs, keys and pins.

Wrought Iron Rims of 30, 33, and 36 inches diameter  
for Wheels of Railway Cars, and of 26 inches diameter  
for Locomotive wheels.

Axles of 24, 26, 28, 30, 32, 34, and 36 inches diameter for  
Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Govern-  
ments and Incorporated Governments, and the Drawback  
taken in part payment. A. & G. RALSTON.

9 South Front street, Philadelphia.

Models and samples of all the different kinds of Rails,  
Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use  
both in this country and Great Britain, will be exhibited to  
those disposed to examine them. 27 Juneover

## SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior qual-  
ity warranted.

Leveling Instruments, large and small sizes, with high  
magnifying powers with glasses made by Troughton, to-  
gether with a large assortment of Engineering Instru-  
ments, manufactured and sold by

E. &amp; G. W. BLUNT, 154 Water street,

J21 St

corner of Maiden lane.

SURVEYING AND ENGINEERING  
INSTRUMENTS.

The subscriber manufactures all kinds of Instru-  
ments in his profession, warranted equal, if not superior,  
in principle of construction and workmanship to any im-  
ported or manufactured in the United States; several of  
which are entirely new, among which are an Improved  
Compass, with a Telescope attached, by which angles can  
be taken with or without the use of the needle, with per-  
fect accuracy—also a Railroad Goniometer, with two Tel-  
escopes—and a Leveling Instrument, with a Goniometer  
attached, particularly adapted to Railroad purposes.

WM. J. YOUNG.

Mathematical Instrument Maker,

No. 9 Dock st., Philadelphia.

The following recommendations are respectfully sub-  
mitted to Engineers, Surveyors, and others interested.  
Baltimore, 1833.

In reply to thy inquiries respecting the instruments man-  
ufactured by thee, now in use on the Baltimore and Ohio  
Railroad, I cheerfully furnish thee the following infor-  
mation. The whole number of Levels now in possession  
of the department of construction of thy make is seven.  
The whole number of the "Improved Compass" is eight.  
These are all exclusive of the number in the service of the  
Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They  
have in fact needed but little repairs, except from accidents  
to which all instruments of the kind are liable.

I have found that thy patterns for the levels and com-  
passes have been preferred by my assistants generally, to  
any others in use, and the Improved Compass is superior  
to any other description of Goniometer that we have yet  
tried in laying the rails on this Road.

This instrument, more recently improved with a re-  
versing telescope, in place of the vane sight, leaves the  
engineer scarcely any thing to desire in the formation or  
convenience of the Compass. It is indeed the most com-  
pletely adapted to lateral angles of any simple and cheap  
instrument that I have yet seen, and I cannot but believe  
it will be preferred to all others now in use for laying of  
rails—and in fact, when known, I think it will be as highly  
appreciated for common surveying.

Respectfully thy friend,

JAMES P. STABLEY, Supt of Construction

of Baltimore and Ohio Railroad.

Philadelphia, February, 1835.

Having for the last two years made constant use of  
Mr. Young's "Patent Improved Compass," I can safely  
say I believe it to be much superior to any other instrument  
of the kind, now in use, and as such most cheerfully re-  
commend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Germantown, February, 1835.

For a year past I have used Instruments made by Mr.  
W. J. Young, of Philadelphia, in which he has combined  
the properties of a Theodolite with the common Level.

I consider these Instruments admirably calculated for  
laying out Railroads, and can recommend them to the  
notice of Engineers as preferable to any others for that  
purpose.

HENRY R. CAMPBELL, Eng. Philad.

Germantown, and Norristown Railroad

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, SEPTEMBER 19, 1835.

**CONCORD, N. H., AND HARTFORD, VT., RAILROAD.**—By a notice in the Burlington Free Press, we find that the people are moving in relation to a Railroad between these two towns. A meeting was held at Lebanon, N. H., on the 19th of August, at which measures were adopted to have the route surveyed. Another meeting is to be held on the first of October next. It will not be many years before there will be a Railroad from Boston to Burlington, and the distance will be performed between the two places in *one day*—by daylight.

**RAILROAD MEETING.**—At a meeting of several gentlemen, residents of the towns of Hartford, Vt., Lebanon, Hanover, Plainfield, Springfield, Enfield, Danbury, Grant-ham, and Sutton, N. H., holden at the Lafayette Hotel in Lebanon, August 19th, 1835, for the purpose of adopting such measures as might be thought expedient to cause the various routes to be surveyed from Connecticut river, in Lebanon, to Concord, with the view to ascertain the nearest, best, and most practicable route for a Railroad between the two last mentioned places: Col. Amos A. Brewster, of Hanover, was called to the Chair, and Lewis Lyman, Esq., of Hartford, Vt., was chosen Secretary. Col. A. A. Brewster, Hon. E. Blaisdell, C. Benton, H. R. Stevens, and Thomas Clark, Esquires, were chosen a

Central and Corresponding Committee.—Committees were also appointed to raise funds and procure the necessary survey of the route.

Resolved, That the Secretary of the meeting request all gentlemen friendly to the construction of a Railroad from Concord, by Lebanon and White river, to Burlington, Vt., to make the necessary arrangements to effect the object as soon as may be, and to request them to co-operate with this meeting at their next and future meetings.

Voted, That the proceedings of this meeting be signed by the Chairman and countersigned by the Secretary, and published.

Voted, That this meeting adjourn, to meet again at the Lafayette Hotel in Lebanon, on the first day of October next, at 10 o'clock, A. M.

**INCREASE OF BUSINESS.**—The following brief statement shows conclusively the immense increase of business in the West. Indeed, we of the East cannot duly appreciate the importance of that fertile region without a visit to it, and a visit is almost sure to make the visitor a resident.

The following is the amount of tolls collected on the Ohio and Miami Canals for the month of July 1834 and 1835.

OHIO CANAL.

Increases in seven of July 1835,

**THE MAZEPPA CAR.**—Our city has long and justly been celebrated for the perfection to which its mechanics have arrived in the construction of Mail Coaches,—the premium having been awarded to Messrs. Slaymaker & Co. at the exhibition in Philadelphia some years since—and bids fair to acquire equal celebrity in the manufacture of Railroad Cars. As an evidence of this we need only refer to the car alluded to at the commencement of this article—built at the shop of Mr. John Baker—which for beauty of material and strength and durability of workmanship is fully equal, if not superior, to any vehicle of the kind that has ever come under our observation. The ends of the car are ornamented with beautifully executed paintings from Byron's "Mazeppa," and the sides with drawings representing the Seasons, upon which much more care and attention appears to have been bestowed than is usually allotted to carriages of this description. The wheels of the car are constructed upon a plan entirely different from Baldwin's patent—the kind most generally in use upon the Philadelphia and Columbia railway—and if we may judge from appearances, we should think it impossible for them to yield under any thing like reasonable pressure. There is also a very material alteration in the construction of the shoulder of the axle and the box for its reception, which to us seems to be decidedly for the better, and which, if we are not greatly mistaken, will go far towards preventing a repetition of the numerous accidents which have occurred along the line, owing to the impossibility of giving to this important part of the running gears a sufficiency of strength to resist the pressure caused by the friction of the wheels in turning the short curves. There are also some other improvements in the construction of the car, to which it is not necessary to refer, as they no doubt suggested themselves to all who witnessed it.

We understand that Mr. Baker has forwarded his car to Philadelphia with the view of disposing of it, and while we indulge the hope that it may be the means of procuring for its builder many orders from abroad, we cannot but regret that measures were not adopted by some one of our railroad companies to retain amongst us a piece of workmanship so highly creditable to the ingenuity and enterprise of a deserving fellow citizen.—[Lancaster Examiner, Pa.]

*Delaware and Raritan Canal.*

To the Editor of the Railroad Journal:

Dear Sir,—I have just passed over the Raritan and Delaware canal, which I found in excellent condition for navigation. You are, doubtless, aware that this canal was originally designed to accommodate the coasting trade, by which the delay, hazard, and expense of the route round the Capes would be materially obviated. In this respect it is an important communication; but, like most other improvements in facilitating intercommunication, it is found to be highly beneficial in promoting other objects than those originally contemplated. By means of tow-boats it affords a very cheap and expeditious transportation between New-York and Philadelphia.

The tow-boats, or barges, are towed through the canal by horses, and on tide water by steam-boats. The barges carry from 100 to 150 tons, and are drawn through the canal by two to four horses. Barges of over 200 tons have passed through the canal. The latter, however, are too large for convenient management, and it is considered, by those navigating and managing the canal, that barges of 100 to 150 tons are best adapted to its navigation. This size appears to move with ease, and are very conveniently governed by the common tiller. I saw a loaded schooner of about 100 tons moving at a velocity of two miles to the hour, drawn by two common horses. The horses worked moderately, and appeared to make no more than ordinary effort. The barges towed easier than the sail vessels of same burden.

A daily line of packet boats has recently been established. One of the packet boats is on the Burden plan: having two long cylinders placed about 10 feet apart, on which the cabin is supported. I saw this boat moving (by three horses) at the rate of about 7 miles per hour. The horses did not appear to labor as much as they do on the packet boats of the Erie and other small canals that I have seen when moving at the rate of 4 miles per hour. The swell created by this boat was less than that made by packets, on the Erie canal at four miles per hour. The appearance was fine: the horses trotted along without any extra effort, and the boat glided elegantly through the water. The average speed of the boat, including all detentions at locks, &c., is seven miles per hour.

The length of the canal is 43 miles. The locks are 24 feet wide and 110 feet between gates. The depth of water is 7 feet, and its minimum width 70 feet. I observed, however, that a great portion of it was from 80 to 100 feet wide.

Experience on this canal exhibits the great economy in transportation on large canals over small ones; and as the expense of construction is not as great in proportion for large canals as for small ones, it therefore seems highly important, when a large trade is to be accommodated, that the canal should have liberal dimensions. In the great canal communications between the Atlantic and Western states, sufficient attention has not been paid to making the navigation the most perfect and economical that was practicable. The length of those canals, and the great amount of property that will ultimately seek a market through them, will demonstrate their want of suitable adaptation to the great and growing trade they were designed to accommodate. The projectors appear only to have viewed the great superiority of a common or small canal over turnpike roads. This, when designed to accommodate the transportation

for short distances, and comparatively for moderate amount, would, doubtless, have been wise; but when applied to lines hundreds of miles in length, where the transportation was materially affected by the value of the article transported, and where the amount of trade is great, this policy does not meet the case. It should not, however, be forgotten, that those canals, already made, were planned in the infancy of trade, with limited knowledge in the science of canals; and it is, therefore, matter of pride, that in a country so recently reclaimed from a wilderness, we have done so much. At the same time it would be unwise not to profit by experience in our future operations in constructing canals.

Respectfully, your ob't sv't,

*Report of the Committee of the Board of Directors of the Elizabethtown and Somerville Railroad, N. J.*

The controversy heretofore existing in regard to the advantages and disadvantages of canals and railways, for the transportation of passengers, merchandise, and country products, may be considered now settled by the experience we have already had in this country. On the route contemplated for this railway, canals and railways will be rendered mutually auxiliary, and the interests of the great West and the Atlantic board alike demand that both should exist. It is necessary for the full completion of the connexion of the sea ports of the Atlantic with the great Western region, that the certainty, the speed, and the advantages of a railway should be added to the facilities of the canals now existing or in progress; it is demanded by the enlightened spirit of the age, and the interests of the patriotic, industrious, and increasing population who are seated on the borders of its route. That route should be selected, not by sectional, local, or selfish considerations, but by liberal and enlarged views, harmonizing the public and local interests, and combining the shortest practicable distances with the facilities of transportation by motive powers. The climate itself fixes the superiority of a railroad on this route over a canal. For at least one fourth of the year the canals are locked up by ice, and during that time a railroad would impart the bustle, activity, and wholesome action of business and trade through a region now paralyzed by frosts.

The route proposed is from Elizabethtown in New-Jersey to Somerville, thence to Clinton, thence to Philadelphia opposite Easton, thence up the Delaware on the New-Jersey side to Belvidere, thence crossing the Delaware to the Water Gap, thence to Pottsville on the Susquehanna, and thence by such routes as will be deemed most advantageous to join the New-York and Erie Railroad. From Elizabethtown a convenient access to New-York will be opened by an extension of the railroad to the waters of the Sound, which the Company are authorized by their charter to do, or by the New-Jersey Railroad, which is now in progress, from thence to Jersey City, opposite New-York. The route from Elizabethtown to Somerville has been surveyed by a competent engineer, who in his report states, "That it can be located on ground favorable for the construction of a railroad at a moderate cost. The curves are few and of a large radii, and the maximum inclination of the slope of the road need not exceed five feet per mile," at any point. The distance will be about twenty-two miles, and this road may be connected by short branches with Rahway and Bridgeton, or extended to

New-Brunswick and Perth Amboy by lateral roads. The legislature of New-Jersey granted a charter for this railway on the 9th February, 1831, and the Company has been organized for the purpose of making it. By the terms of the charter the road is free from taxes until the net income amounts to seven per centum per annum upon the amount of its cost, and then the Company are to pay to the State of New-Jersey annually the *one half of one per centum* on the said cost, in lieu of all taxes and imposts. The State has reserved the right of taking the road at the expiration of fifty years from its completion, on a valuation not to exceed the first cost of the road and its appendages; the road to be completed and in use, from Elizabethtown to Somerville, by the 4th of July, 1838.

On the 8th February, 1833, the legislature of New-Jersey, by a supplement, authorized the said Company to extend the said road from Somerville, on the most eligible route, to the village of Clinton, in the County of Hunterdon, and from thence to Belvidere, with the right to make a branch to the Delaware, at any point between the mouth of the Musconetcong Creek and the Easton Delaware Bridge; that extension to be completed in ten years from the passage of the supplement.

This route has been partially surveyed, and a recognizance has been made of the residue by a competent engineer. The route from Somerville to Clinton is of easy grade, not exceeding seven feet per mile, distant about twenty-one miles; from thence to Belvidere the location has not been fixed, but it is certain, that the distance from the Sound to Belvidere will not exceed seventy-three miles, nor the cost twelve thousand dollars per mile; the grade will be an easy descending one for the greater proportion of the distance, in the valley of the Water Courses, and will be accommodated to the use of motive power throughout.

This road will pass through a well settled portion of the Counties of Essex, Middlesex, Somerset, Hunterdon, and Warren, in the State of New-Jersey, rich in agricultural products, abounding in water power, limestone, and iron and copper ore, and the mountains and hills adjacent to the route, are known to be filled with mineral treasures. The country on and adjacent to the route is not only one of the most fertile in the State, but is remarkable for its picturesque beauty, and is inhabited by an industrious, enterprising, and increasing population. The route passes through or near the flourishing villages of Elizabethtown, Westfield, Scotch Plains, Plainfield, Towtown, Quibbletown, Boundbrook, Middlebrook, Somerville, Pluckemin, New-Germantown, Mechanicsville, Readingtown, Flemington, Whitehouse, Lebanon, Jacksonville, Clinton, Quakertown, Pittstown, New-Hampton, Asbury, Bloombury, Phillipsburg, Oxford furnace, Oxford meeting-house, Harmony, and Belvidere, in New-Jersey, and Easton, in Pennsylvania. This route will necessarily draw to itself the whole of the trade of Easton and its vicinity, and a great portion of the Counties of Lehigh and Northampton, in Pennsylvania, and of Warren and Somerset, and a large part of Hunterdon, Morris, Middlesex, and Essex, in New-Jersey. It will command the trade of the rich and productive valleys of the Raritan, the Musconetcong, and the Pequest.

The County of Warren has upwards of sixty stores, fifty grist mills, and forty-five saw mills, sixteen carding machines, seven furnaces for casting iron, two cotton and woolen factories, two fulling mills, four oil mills, five plaster mills, two hundred and

thirty-five tan vats, one glass factory, six distilleries of grain and twenty-five of cider; and has a population of upwards of twenty-five thousand souls. It abounds in lime stone and iron ore, and her mountains are rich in various valuable minerals. It contains about 140,000 acres of improved lands, and it is among the most fertile and productive grain counties in New-Jersey, and it is supposed to produce annually upwards of one million bushels of grain, of various kinds, for market.

The water power at Belvidere includes the whole of the river Pequest, and will afford fifty feet head and fall, and is equal to seventeen hundred and seventy horse power, and if applied in the best manner for manufacturing, would be sufficient to manufacture two hundred thousand barrels of flour per year.

Oxford furnace also possesses a valuable water power, which is applied to saw and grist mills and iron works. The product of those works yearly is three hundred tons of stove plates and five hundred tons of pig iron, and are rapidly increasing. The Musconetcong also supplies a very valuable water power at different points, besides those furnished by its tributaries.

The County of Northampton, in Pennsylvania, which bounds on the Delaware for a great distance, has 181 stores, fifty flouring mills, which manufacture upward of 337,500 barrels of flour and corn meal for market yearly; there are also in it seven oil mills, ten tanneries, seven distilleries, three blast furnaces, five forges, two trip-hammer mills, and a variety of smaller iron works, one gun factory, numerous saw mills, bark and country grist mills, clover mills, and various manufactories of saddlery, hats, &c. &c. The amount paid at Easton, for logs, by two individuals, this spring, exceeded \$40,000, and at least three millions of oak lumber is rafted down Broadhead's Creek, and it is estimated that at least 50,000 tons of lumber descend the Delaware annually. The amount of merchandise received at Easton, for that place and the adjacent country, annually exceeds 1,000,000 of dollars, and the exports in butter, lumber, castings, bar iron, slate, machinery, &c. &c., are very considerable; it also exports upwards of eighteen hundred tons of pork annually, besides a large amount in fat cattle, sheep, &c. There are three daily lines of stages from Easton to New-York, one by Morristown, and the other two by Somerville, and it is the starting point for numerous stages up the Lehigh and Delaware, and to the Susquehanna. The exports of Northampton may be fairly estimated at fifty thousand tons, and her imports are also very considerable, amounting in plaster, salt, and fish alone, to six thousand tons, besides the various articles of merchandise demanded for its consumption.

The greater part of Hunterdon, from the Hopewell line North, will travel to New-York by this route, as will also a great portion of the County of Bucks, in Pennsylvania.

From estimates made with great care, and drawn from accurate sources, it may be safely assumed, that the first year that this road is completed to Belvidere, the tonnage that will pass to market upon it will exceed 125,000 tons, without calculating the droves of cattle and live stock, lumber, coal, lime and lime stone, and the return tonnage.

The lime stone region terminates South at Clinton, and the country below that point must draw their supplies of that necessary article for building and manure by this road.

The return tonnage may be estimated at 25,000 tons, and passengers both ways at sixty thousand per annum. The increase after the first year can be readily calculated by data furnished by other railways, alike favorably located for trade and travel.

Such is the favorable location of this line of railroad, and the fertility, productiveness, and increasing prosperity and population of the region through which it passes, that each section from Elizabethtown to Belvidere, as completed and opened for use, will certainly pay an interest of at least seven per centum on the cost of that part of it brought into use, while the other portion is in progress.

It is to be observed, that this route, from its location, and the facilities which it will afford for the purpose will in all probability be selected to carry the mail for the different post offices on its line.

The above calculations have been made upon the idea that the railroad from Elizabethtown should terminate at Belvidere; but it is not so intended; it is meant to form a part of the continuous line of railroad from the Atlantic board to Lake Erie, and to bear to market the immense trade that will pass on this route from the far West, and from the fertile valleys of the Susquehanna, the Chemung, the Genesee and the Allegany; and the Southern tier of Counties of New-York, the anthracite of Luzerne, and the bituminous coal of Bradford and Tioga Counties. It will connect with the Susquehanna and Delaware Railroad, at Belvidere, thence through the Delaware Water Gap, Stroudsburg, the Valley of the Roaring Brook to the Lackawanna at Centerville, thence down the Lackawanna to Pittston, on the Susquehanna. A charter was granted by the legislature of Pennsylvania, by an act, 3d April, 1826, to a Company to make this road. This Company has been incorporated and the route surveyed, and the road commenced, with a capital sufficient to accomplish the work.

The dividends of this Company are limited to twelve per cent. on the amount expended in the completion and improvement of the same; they may purchase and hold one thousand acres of coal land in the townships of Pittston and Providence, in the County of Luzerne. The railroad to be completed in ten years from the 25th January, 1831. The route of this road passes for nearly eighteen miles through a clearly defined coal region, and the last ten miles of it may be considered as one continual coal bed. Besides, it will command the whole coal trade of the Lackawannock valley south of Carbondale. Offers have been made to the Company by several persons of known ability to furnish coal, and place it in the Company's cars, on the railroad, at fifty cents per ton, and it is not doubted that contracts for any quantity can be made for 37½ cents per ton.

The cost of this road from Pittston to Belvidere, seventy-four miles, is estimated by Ephraim Beach at \$624,720 60, and the route admits of the advantageous use of locomotive engines, except in ascending from the Lackawanna valley, where stationary power would be required to overcome about 600 feet; the water of the Roaring Brook will be used for the moving power. At the summit a continued line of level is kept for sixteen miles, and the line is favorable in regard to curves. Captain Beach says in his report, "The scheme is not only practicable, but the object may be effected without encountering any extraordinary difficulties, and at a comparatively reasonable expense."

The coal in this region occurs not in

veins, but in layers and repeated strata, and "the whole is completely underlain by coal beds," and the quantity is inexhaustible and defies monopoly. Unlike most mining districts, this section of the country abounds in agricultural products, and the soil in the Lackawannock valley is generally fertile, and the beautiful valley of Wyoming, and all the main river lands, are celebrated for their richness and fertility.

At Pittston a choice is presented, to unite with the proposed route of the New-York and Erie Railroad at Binghamton, by the Leggett's Gap Railroad, or at Shepherd's Corner, near Tioga Point, by the Susquehanna Railroad, for both of which liberal charters have been granted by the legislature of Pennsylvania. The latter is the nearest route, and of very easy locomotive grade, not being at any point over two and a half feet per mile, [see Randle and Bennet's report to the Pennsylvania legislature,] and with very favorable curvatures, and can be made at a distance of seventy-five miles at a very moderate expense, less than eight thousand dollars per mile.

It will be thus evident that this route will be extended by the New-York and Erie Railroad to Portland, on Lake Erie, at a distance of 216 miles from the intersection with the York and Erie to Portland, and at an aggregate distance by these lines of 438 miles from the city of New-York, to Portland on Lake Erie, and being 70 miles nearer than by any other practicable route.

If the route of the Susquehanna Railroad should be adopted from Pittston to the New-York line, it will pass within nine miles of the bituminous coal regions of the Counties of Bradford and Tioga, and the course of the Lycoming, which runs into the Western branch of the Susquehanna and the Towanda, which empties into the North branch, and interlock at their summit, afford a very favorable route for a railroad to open a communication with the Elmira and Williamsport Railroad, which will soon be in progress, and will pass on its route the best bituminous coal beds in that country. By this route, and this only, can New-York hope to compete successfully with other markets for the direct trade of nearly 6,000,000 of acres of the most fertile part of her Southern boundaries. By this route, and this only, can the nearest practicable route for an easy locomotive grade, be extended in nearly a direct line from New-York to Lake Erie, accommodating the valleys of the Northern and Western branches of the Susquehanna. By this route, and this only, can the anthracite and bituminous coal be found in sufficient abundance on or in the vicinity of a railroad route, and meet an advantageous or remunerating price, whether transported in the direction of the lakes or the Atlantic; the demand each way will continually increase with the increasing prosperity of the different sections; and it must not be forgotten, that the bituminous coal of the Counties of Bradford and Tioga, and the anthracite of the Southern valley of the Lackawannock can reach New-York and the Northern and Eastern portions of New-Jersey, which abound in iron ore, one hundred miles nearer by this route than by any other practicable route. This route too will be open at all seasons of the year.

It would be useless to attempt to estimate the value of the descending trade of the Susquehanna. It is increasing every year, in a ratio more than proportionated to the increase of the facilities of travel. By an estimate which is supposed to be greatly below the actual amount, it is stated that

at least 200,000 tons of bread stuffs, and other agricultural products and lumber, descend the Susquehanna from within twenty miles of the New-York line annually. The Counties of Luzerne and Lycoming each consume one million of merchandise, and the consumption of Susquehanna, Bradford, Tioga, Wayne, and Pike counties, may be averaged at half a million each. The region through which this continuous line of railroads, from New-York to Tioga Point, will pass, abounds in forests heavily timbered with white and yellow pine, hemlock, curled and birdseye maple, cherry, poplar, &c., &c. Much of the land is rich and fertile, and is fast being brought under culture. The country abounds with fine water power and all the materials for mining operations. If in addition you impart to it the facilities of a railroad, connecting the Lakes with the Atlantic, the water power so abundant and so powerful on this route will be immediately called into action for manufacturing purposes of every kind.

It is a fact which cannot escape the most inattentive, that the trade of the Northern branch of the Susquehanna, and its various tributaries, will, by this route and the Delaware section of the Pennsylvania Canal, or the Delaware and Raritan Canal, reach Philadelphia by a shorter distance than by any other connected line of artificial communication executed or in contemplation; and that the descending and ascending trade of the great West, to and from the cities of Philadelphia and New-York will be necessarily attracted by this route, which will be connected with "the Camden and Amboy" and "the New-Jersey" railroads. In distance, in ease of grade and curvature, adaptation to motive power, and profit, this route affords more inducements for the investment of capital than any other railroad now in progress; and while its profits must increase with the prosperity of the country, its location is protected by the passage of the Delaware Water Gap from all competition, thus enjoying a natural monopoly and all its advantages, without its odium.

*On the Obstruction of Cast Iron Water Pipes, by the formation of Nodules of Oxide of Iron within them.* By M. PAYEN.

[Translated for the Journal of the Franklin Institute, by Jos. Wharton, at the request of the Committee on Publications.]

A singular effect has been lately observed to take place by use in cast iron water pipes, in certain cities. The passage of the water becomes gradually obstructed, by the formation of nodules of impure oxide of iron, of a light brown or greenish color, which adhere to the internal surfaces of the pipes.

This subject being one of the greatest importance in connection with the health of cities, and the agriculture of various districts, required an elaborate investigation, which I undertook, and of the results of which the following is a succinct account.

All soluble substances that give an alkaline reaction to water, such as potassa, soda, ammonia, and lime, the carbonates of potassa, of soda, and of ammonia, the borate of soda, and the sub-acetate of lead,

are capable of preventing the oxidation of iron.

The relative proportions of these substances, and of the water, required to produce the effect, varies with the alkaline agent employed, and is also affected by the presence of certain foreign salts; the alkaline agents being the same, the nature and quantity of these salts determine the proportions.

When the quantity of alkaline matter is insufficient, oxidation ensues; but it is remarkable that all the points of the surface are not, in this case, equally oxidized, so that the nodular form of the concretions must be assumed from the beginning. The preserving force is overcome only in places where the continuity of the surface has been interrupted, even although it be by an almost imperceptible division. Thus, for instance, the lines on fibrous iron, and the points where the parts of the iron are separated by foreign bodies, are oftentimes pointed out by traces of greenish oxide, which gradually fill up, while the rest of the surface preserves, for a long time, its metallic aspect; and hence the advantage of an iron as mechanically pure as possible. The points of contact between a connecting pipe, and the sides of a main, or between two pipes, are likewise sufficient to determine the effect.

The following are a few experiments upon these points.

A cylinder of polished iron, immersed in a saturated solution of pure potassa, diluted with 1000 times its volume of water, (the temperature being 59° Fahr.) was preserved untarnished for a long time; but as the carbonic acid of the air gradually weakened the intensity of the alkaline action, signs of oxidation began to exhibit themselves at various points, and became more and more apparent, while the greater part of the surface preserved its lustre after the lapse of a year.

Conical concretions of oxide were gradually formed on the surface of an iron cylinder, when the latter was immersed in water containing 0.02 parts of its volume of a saturated solution of carbonate of soda. The color of these concretions was a greenish brown, which acquired a yellowish cast at their summits, while the base in contact with the metal retained its original greenish brown color. The liquid was not protected from the air.

The same saturated solution being used, but diluted with fifty-nine parts of water, and kept for a year, in an open tube, in contact with polished cylinders of iron, greenish concretions were first formed, which slowly passed round the cylinders, and gradually assumed a beautiful yellow tint, whilst the rest of the surface, even of that part which, by the evaporation of the liquid, was uncovered, preserved its metallic state. In the same circumstances, the iron has been completely preserved from oxidation in water containing 0.023 of a saturated solution of carbonate of soda.

In a saturated solution of chloride of

sodium,\* protected from the air, there appeared, on the surface, and, it is to be particularly observed, *on the points of contact* between several bars of iron, only some protuberances of greenish oxide, the remainder of the surface preserving its metallic lustre after the lapse of a year. In a similar experiment made in contact with the air, the oxidation continued, and assumed the color of rust, beginning with the parts nearest the surface of the liquid.

A solution saturated with marine salt, and carbonate of soda, preserved iron entirely from oxidation, for the same space of time, notwithstanding the presence of atmospheric air, and a crystallization of a part of each of the two salts.

The same solution, diluted with nine volumes of water, afforded concretions of oxide.

In endeavoring to obtain, in accordance with the above experiment, the exact proportions of water, of chloride of sodium, and of carbonate of soda, the most favorable to the formation of local concretions of oxide, I found that a saturated solution of the two last, (the solution being made at the temperature of 59° Fahr.) diluted with seventy-five times its volume of water of the Seine, (see note 3,) and filtered, produced, in less than a minute, an oxidation both on wrought and cast iron. The effect was first shown by the appearance of points of a pale green; in ten minutes' time, the lines were well defined.†

When, in compliance with a suggestion of M. Becquerel, the power of electric conductivity was increased, by bringing, by means of a wire, a fragment of well calcined charcoal into contact with a polished bar of wrought or cast iron—the other circumstances being the same as in the preceding experiment—the greenish protuberances were developed still more rapidly, and in much greater number.

In weak alkaline solutions of the same substances, freed from atmospheric air, oxidation does not ensue.

In those containing atmospheric air, oxidation is arrested when the access of the exterior air is prevented.

When the air of the atmosphere has free access, the concretions nearest the surface pass into a higher state of oxidation, while the greenish oxidation continues, at other parts of the surface, on the points at which it began.‡

The figure of the concretions is sometimes irregularly rounded, sometimes conical, and, at times, variously ramified into winding bands.

\* (1) In making a saturated solution of chloride of sodium, in water of the Seine, (the liquid suffered a contraction equal to 0.03 of its volume, and disengaged 0.015 of the same volume, of gases contained in the water. The temperature was 59 Fahr., and the pressure 30 inches.

† (2) The chloride of sodium, when present by itself, in small proportions, in water, determines, on the surface of polished iron, local oxidations, which remain greenish colored the longer, and preserve the remainder of the surface the better, accordingly as the iron is farther removed from the surface of the liquid in contact with the air; but these oxidations do not assume the nodular form.

‡ (3) In all the preceding experiments, made with a view to their practical application, the water used

Bars of wrought and cast iron, polished, which have been, for the last four days, immersed in water, that had previously stood in contact with a portion of white marble, in the form of a well washed powder, already exhibit, near the surface of the liquid, points of a greenish oxidation, and rust in a flocculent state.

The following conclusions may be drawn from the preceding facts, and others not mentioned.

1. That all solutions, having a slight alkaline reaction, may, while the general surface is preserved, occasion the formation of local concretions of oxide, at certain points of the surface of iron immersed in them.\*

That the general character and rapidity of this process varies with the presence, and according to the proportions, of atmospheric air, and different salts, that may be brought into action, and is further determined by the presence of breaks in the continuity of the surface of the metal immersed, whether these interruptions exist in a single piece, or at the lines of separation between different pieces of iron, or even between the latter and other substances.

3. That acid solutions determine a uniform, and less bulky, oxidation; on copper, both acid and alkaline solutions determine a general oxidation.

Local concretions must then be expected to ensue in wrought or cast iron pipes, when exposed to a current of water slightly saline, and having a feeble alkaline reaction. In such case, it will be necessary either to abandon the use of this metal, or at least to contrive convenient places of access to the pipes, at short distances from each other. In this case, owing to the minute state of division of the particles, and the granular formation of the concretions, the obstruction may be removed by the application of a gentle friction, or by the assistance of a diluted acid, too weak to injure materially the metallic parts.

*Note by the Translator.*

The general properties developed in this paper, as belonging to all alkaline solutions, are considered by the author to present a new series of electro-chemical actions to the attention of the scientific chemist.

[From the Journal of the Franklin Institute.]

*Remarks in relation to some new Concretions, produced artificially on Iron.* By M. PAYEN.

In a recent paper, the results of which

was taken from the river Seine, and filtered after its mixture with the alkaline solution, and the subsidence of the precipitate, (which fell in consequence.) The temperature during the experiments varied from 59 to 62.6, and from 68 to 69.8, Fahrenheit. Several of these experiments, repeated with the use of distilled water, gave the same results, when the proportions of the alkaline substance, of the atmospheric air, &c., were the same.

\* (4) Wrought and cast iron, half immersed in a weak ammoniacal solution, were preserved, by the vapor of the ammonia mingling with the air above the liquid, during all the variations of temperature through out the year. The solution contained 0.1 of ammonia. All the above mentioned concretions are composed of a mixture of hydrated protoxide and peroxide of iron; the proportion of the latter slowly increases.

have been verified by M. M. Becquerel and Dumas, I made known a method of forming the protoxide and peroxide of iron, in the shape of nodular concretions, on certain points of the surface of iron,\* while the remainder of the surface preserves unchanged its metallic state.

An investigation, having its origin in the electro-chemical theory, and the properties of alkaline solutions, has led me to the discovery of another kind of local concretions, produced by a series of still more complicated reactions.

A polished cylinder of soft iron was kept immersed, for a year, in a close vessel, in a solution of sub-acetate of lead, and consequently exposed to the influence of an alkaline reaction; for a short period, no signs of oxidation were observable, but it afterwards became studded with a number of spongy, greyish excrescences, which presented themselves on a line parallel to the axis, (see preceding paper.) The remainder of the surface of the iron preserved, unaltered, its original appearance.

The concretions were made up of small particles, aggregated in the form of a metallic sponge, that presented the appearance and ductility of lead.

A slight friction was sufficient to unite the particles when separated, and to give the mass the brilliancy of that metal.

When flattened together under a slight pressure, and heated in a tube out of contact with the air, they melted, and hardened, on cooling, into a dross, that possessed all the properties of lead.

The liquid itself remained limpid and colorless throughout the year; afterwards, when exposed to the air, it quickly assumed a yellowish brown color, which gradually deepened; it still possessed a feebly alkaline character.

A portion of the liquid being treated with sulphuric acid, acetic acid was developed. Another portion, by the action of a soluble sulphate, gave a precipitate of sulphate of lead, and the supernatant solution had all the properties of the salts of iron.

The tube in which the solution, and the immersed iron, were enclosed, contained, then, evidently, the following substances, present, at the same time, together.

1, sub-acetate of lead; 2, metallic iron; 3, lead, in the form of a concretion; 4, acetate of iron, partly acetate of the peroxide.

It appears to me to follow, from the preceding facts, that, at the points where, by the presence of foreign bodies, and interruptions in the continuity of the surface, the elements of a pile are constituted, the iron is oxidized at the expense of the oxide of lead, the latter metal being revived, and aggregating in concretions, at the same points, while the oxide of iron, united to its equivalent of acetic acid, diffuses itself in the liquid.

By the continuance of the same series of reactions, the volume of the concretions is augmented, while, by the alkaline

reaction of the undecomposed sub-acetate of lead, the rest of the surface of the iron is preserved from oxidation, and is thus enabled to maintain its metallic lustre.

By our advertising columns it will be seen that the magnificent undertaking, the New Orleans and Nashville Railroad, is to be commenced immediately, the first fifty miles being advertised for contract.

The length of the road is 565 3-4 miles, estimated to cost \$10,063,946, including the machinery, depots, water stations, &c.

This estimate is predicated upon a graduation not exceeding ten feet rise per mile towards New Orleans; or twenty feet from it. There will be no curvature less than five thousand feet radius. The rails will weigh not less than forty-five lbs. per yard.

We learn that its projectors have determined to make it one of the most perfect works that the present state of science and art will admit. When completed, the time between Nashville and New Orleans will not exceed thirty-six hours.

This, by facilitating the mails and transit of passengers, will render it, in a commercial point of view, the most important improvement ever projected, and in case of invasion, the South may have a more prompt resource in the western militia,—as cantonments in the vicinity of Nashville, where the abundance of provision and health of the climate are equal to any in the world, can be made for the rendezvous of the Western Army, and when required, transferred to the coast at a single day's notice.

Mr. Ranney, the Chief Engineer, is now on his way to Europe, with a view to make contracts for the delivery of iron, and the examination of the machinery and roads now in use or progress there.

Should the Virginians determine to connect their contemplated James River improvement with this work, we may expect to travel from Washington to New Orleans in four days, with an ease and comfort never before contemplated.—[Globe.]

Mr. Hoffman, the President of the Company, and Mr. Woodruff, one of the directors, and agent of the road, are also in Baltimore, whither they have come for the purpose of examining our railroads, and the machinery connected with them."

ACCIDENT.—As the locomotive on the Paterson Railroad, with a train, composed of transportation and passenger cars, was approaching the depot at Paterson, on Monday evening, an axle of the leading transportation car gave way, which overturned that and the next car, and threw the third off the track. The locomotive and passenger cars remained upon the track uninjured, though the passengers felt a shock by the concussion. Mr. Speer, the conductor of transportation, a very industrious and sober man, was seated on the car at the break, and unfortunately was crushed to death under the load. No other person was injured.—[Gazette.]

G. S. NEWTON, Esq.—We regret to announce the death of this distinguished artist, which took place at Chelsea on the 5th of August. He was in the fortieth year of his age. The London Gazette, in noticing his decease, says that "his talents as an artist are too well known to the public to render it necessary for us now to expatiate on them. In the representation of beauty, in propriety of character, in delicacy and force of expression, in skill in composition, in vigor of effect, in richness of coloring, and in painter-like execution, he has left few, if any, superiors.

DEATH OF MR. SADLER.—The decease of this gentleman is also announced in the London papers. He died in Ireland, about the 29th of July. He distinguished himself within the last eight or ten years by his parliamentary efforts, and also by his writings on political economy. His principal work was an elaborate treatise on "The Law of Population," in two volumes octavo, which was made the subject of one of the strongest, ablest, and bitterest articles that ever appeared in the Edinburgh Review.

Extract of a letter, dated Near Darien, Sept. 1.—I have nothing worth communicating, save the prospects of the Rice Crop. I commenced cutting on the 19th ult. and have about one third of my crop in the barn yard, and it is in most beautiful order, never having had a shower of rain upon it. I shall endeavor to have the first Rice in market this fall, and have no doubt it will sell well.—[Charleston Courier.]

\* The preceding paper is the one referred to by the author.—[Translator.]

Fig. 1.

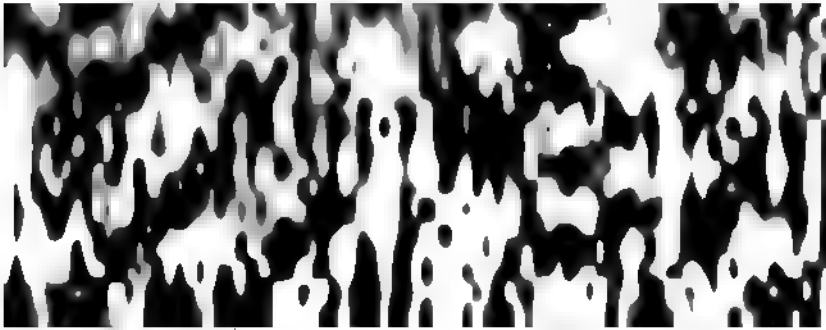

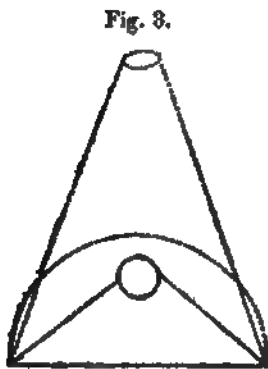

Fig. 2.

[From the London Mechanics' Magazine.]  
HYDRAULIC BLAST WHEEL.

In foundries, smithies, and other manufacturing, large quantities of atmospheric air in rapid motion are in constant demand, and a large proportion of the motive power is spent in the supply. The pressure of fluids being equal in all directions, the aggregate amount of force employed in transmitting air by means of bellows, air cylinders with pistons, &c. is very considerable, there being the same pressure on every square inch of the blowing apparatus as on the like space of the orifice through which the air is transmitted.

The accompanying drawings represent a blast wheel lately invented by me, of which the following is a description. I have had a model of it made, and it fully verifies the correctness of my calculations; and in this case the effects must be the same in proportion on a large scale.

Fig. 1. A is a hollow cylinder (the length of twice its diameter,) which is made to revolve on the pivots O by means of a rope or belt acting on the pulley B, or by any other mechanical power. C is a stationary nose or tube, fixed to the side of the oval trough D. The trough is nearly full of water, its level being above the centre of the cylinder A, and of the small cylinder within it, hereafter described. Within the cylinder A is a spiral leaf wound round a cylinder of about  $\frac{1}{4}$ th of the diameter of the

external one. The size of the internal cylinder need not be increased in proportion to that of the external. The leaf is soldered to both cylinders, and so rendered airtight; it may be made of the slightest material.

Fig. 2. The water is here seen occupying the lower half of the cylinder and trough, the top being always filled with air. On the wheel's making one revolution, the water in E is conveyed into F; that which was before in F escapes at G, and flows round the side and bottom of the trough, outside the cylinder, to re-enter the latter at H. The air in I (which is continually supplied by atmospheric pressure of 15 lbs. to the square inch) is conveyed to K, and so in proportion for less than a revolution; and the air which was before in K is forced through the pipe at C, to which branch pipes may be attached. A continuous blast of air is thus produced, and may be conveyed to any part of a building. The pressure of the water being equal on all sides, and as it is set in motion by the inclined plane of the screw, but little power is required to keep the wheel going, for the particles of fluids move easily amongst themselves. The trough should be of an oval form. In order that no air may escape between the tube and the cylinder, a small strap of leather is fastened to the tube (which is fixed) to lap over the cylinder at P, fig. 1, and is kept down by a small weight, hung at the corner of each side, thus,

No air, once enclosed or detached from the atmosphere by the end H of the spiral leaf being immersed in the water, can possibly escape but through the nose or tube.

Fig. 3. Transverse sections of both ends of tube; and outline, as seen from its under side.

The wheel may be made of any size required. To ascertain the quantity of air discharged at each revolution: First, find

the whole contents of the cylinder, which we will suppose to be 14 feet in diameter, by first finding the area of the base by multiplying the square of the diameter by 7854; then multiply the area by the length of 28 feet, thus,  $14 \times 14 = 196 \times 7854 = 154$  nearly,  $\times 28 = 4312$ , contents of cylinder. But as it takes two revolutions to empty the cylinder,  $4312 \div 2 = 2156$  feet of air and water discharged at each revolution,  $2156 \div 2 = 1078$  feet of air less 78 feet for internal cylinder, &c. = 1000 cubic feet of air discharged at every revolution. If the motive power, or the velocity, cannot be easily regulated, a sliding-valve may be made in the side of the tube C.

ALFRED T. J. MARTIN.

Helston, Cornwall, June 6, 1835.

P. S.—Since writing the above, a practical difficulty has been suggested to me, viz. that the pressure of air for smelting should be 2, 3, and even 4 lbs. to the square inch, equal to the pressure of a column of water about 7 feet high. I do not see how this desideratum can be obtained by the foregoing plan; but still the invention may prove useful where large supplies of air are required without any considerable pressure.

*Abstract of the Specification of a Patent for a Mode or Machine for making Wrought Nails, Tacks, or Spikes. Granted to WM. C. GRIMES, York, York county, Penn., Dec. 17th, 1834.*

To make wrought nails by machinery is an object that has been sought by numerous individuals; hence it may be useful, in order to point out more clearly the novelty in the present plan, to refer to the general principles upon which preceding machines, or processes for that purpose, have been founded.

One of the first, and it is believed, an almost universal principle, that has been observed in previous attempts to make wrought nails, has been to make them from rods that were rolled or slit to the size of the larger part of the body of the nail. To taper, or to give to the nail its requisite form, from such rods, various modes have been essayed; swaging, forging, and rolling, have been tried, but the latter by far the most generally. Modifications of these principles, to effect the object proposed, have been too numerous to be here detailed. But whatever has been the modification of the machine, it has generally embraced or been constructed to operate upon only one of these principles. The novelty of the present machine consists in its being constructed so as to combine several of these principles at the same time, viz. cutting, swaging, or pressing, and forging, or percussion, and to make the novelty more apparent, the nails, &c. are not to be made from rods of the size of the body of the nail, but from broad plates, and these at a red heat. These plates are to be prepared by rolling, after the manner of plates for cut nails, but with this difference—they must be of perfectly sound iron, and two or three times as broad as the length of the intended nail, but of about the same thickness. These plates are to be cut off transversely into pieces, about two-thirds the length of two nails. From the sides of these pieces, or plates,

the nails are to be formed and cut, the length of the nail running with the grain of the iron, or parallel with the length of the original plate. These plates are held, turned over, and the nails cut from the sides or ends of them, in the same manner as is practised in making cut nails, but with this difference—in making cut nails, the plate is either cold, or at what is called a black heat, whilst in my process the plates are to be at a high red heat. In making cut nails, they are cut off with a regular taper from end to end; in this process they are tapered not more than half their length. In making cut nails, the width of the plate is the length of the nail; in this process the plate is cut into lengths transversely, which length forms two nails, by their points overlapping each other. In making cut nails, the first action upon the nail is to sever it from the plate; in this process the nail is nearly formed before it is severed from the plate.

As the plates are cut at a high red heat, they would soon destroy the temper of the steel cutters or dies, if continually applied, as in making cut nails; therefore, to prevent such injury, I cut a few nails in rapid succession, and then allow a short intermission, when the plate is withdrawn, and a jet of water is applied for an instant to the dies, which continue in motion, the plate and the jet of water being applied alternately to the dies.

Two or more of these plates should be in the fire at a time, as only a part of one plate can be cut or formed into nails without re-heating. The plates may be changed in the furnace during the time that the jet of water is let on to the dies.

The water in the pipe that conducts it to the dies should be under considerable head, or pressure, and the starting and stopping the jet may be done in various ways; the valves or cocks may be opened at regular intervals by the machinery, or a treadle may be applied for that purpose.

When the nail is to be formed and cut from the plate, such a portion of the latter as shall be necessary is placed between the jaws or dies, constructed for the purpose, and which are parallel with the end or edge of the plate, for about half or two-thirds of the length of the nail. The remainder of the dies are turned off at a slight angle, running out to the edge of the plate, thus forming the taper or point of the nail; the plate is then turned over, and its opposite side brought into the same position between the jaws, and another nail is cut, the point of which commences at the same point in the plate that the taper began in the preceding nail.

A heavy hammer for striking a head upon the nail is placed in front of the end of the jaws; this hammer is fixed upon the end of an upright rod, or helve, the lower end of which is fixed to a horizontal shaft, furnished with round tenons, or gudgeons, that work in suitable boxes on each side of the frame of the machine. From the side of this shaft, an arm projects, being inclined downwards; this arm may be about one-third of the length of the said helve. A beam or lever,

whose fulcrum is near its centre, lies nearly in a horizontal position, with one end beneath the fly-wheel, and the other above the said short arm, to which it is jointed by a link. A cam on the periphery of the fly-wheel acts upon the end of this lever, or beam, the latter being gradually borne down by it, while the opposite end of the beam rises, and by its aforesaid connection with the hammer, the latter is thrown back to a proper distance; the said cam then terminates abruptly, and by a strong spring the hammer is brought forcibly upon the iron which is to form the head of the nail.

I intend sometimes to form the head upon the nail by pressure, instead of percussion.

Any competent power may be employed to impel the machine.

Machines greatly differing in form, and in the particular arrangement of the respective parts, may be constructed upon the preceding principle to produce similar results, or effect the same end by similar means. I therefore do not intend to limit myself to the particular arrangement herein specified, but to change such form and arrangement as I may think proper, while the principle remains unchanged.

What I claim as new, and as my invention, and for which I ask letters patent, is, 1st. The making or forming wrought nails, tacks, or spikes, from or upon the edges or sides of metallic plates, by pressure and cutting, after the manner, or upon the principle, herein specified.

2d. The manner of severing the plate from the nail, so that a part of the latter is left standing out beyond the end of the jaws as herein before described.

3d. The side jaw by which the plate is gauged, and the nail compressed, and removed from the jaws.

4th. I also claim the general construction and combination of the respective parts of the above described machine, by which general combination it derives that character by which any competent machinist will readily distinguish it from any of the various nail machines heretofore in use.

But I do not claim as my invention the fly-wheel, cams, levers, or any other part of the machine, taken separately and individually; but, as aforesaid, the combination of these parts upon the principle herein fully set forth. Nor do I claim the forming of nails from nail plates, by cutting them with the grain, that having been already done; but in this particular I confine myself to the peculiar manner in which the cutting is effected.

WILLIAM C. GRIMES.

[From the London Mechanics' Magazine.]

**EVIL EFFECTS OF THE DIVISION OF LABOR.**—In attempting to prove that the minute subdivision of labor has an evil tendency, I am aware that I shall meet with few who will admit the evil to be so extensive as I shall endeavor to point out; and it is very probable I shall be written down by some of the many able correspondents of the *Mechanics' Magazine*. But as the follow-

ing facts are the results of long observation and experience among the working classes, I have resolved to publish them anonymously, in the hope that they will meet the eye of some who may be benefitted by them; and should they be the means of convincing even one, I shall consider myself happy in having brought the subject into notice. I have myself served an apprenticeship to a mechanical profession, and had then ample opportunities of observing the causes that tend to bring about the moral degradation of some of the working classes.

That the division of labor produces a cheaper article, and is a great source of national wealth, I readily admit. I believe were it not for this very cause, Britain would ere this have lost her political status among the nations. Groaning under a load of taxation, which no other nation on earth could have borne, we have been driven into an artificial state of society, and the division of labor with all its attendant evils is one of the results. This is illustrated by the fact that we export machinery to countries where workers are obtained at half the price: and yet these countries are unsuccessful competitors in the same market with the poor tax-eaten British. Our national vanity whispers that this is owing to our superior genius; but I contend that it is our artificial mind-degrading system of dividing labor, which by making individuals do only *one part of a thing*, with mechanical, or rather slight-of-hand, rapidity, enables us to produce a whole as cheap as our foreign brethren.

But the effects of this system upon society is truly deplorable. A poor boy, with very little education, is bound an apprentice for five or seven years, to do one particular act; he commences cheerfully, and in a few weeks can manage it completely; the only difference between him and a journeyman being that he takes twice the time. He is now doomed through life to be a *mere machine*; all the delight he felt in learning his trade is over; he has no more mental work to perform, and he goes on from day to day with his monotonous task without excitement of any kind, save the temporary one of the gin-shop: there, amongst the rudest ribaldry and mirth, he is exhilarated and comparatively happy. Next day he returns to his labor in the most melancholy and discontented mood, and hastens on with his work to procure the means for "a hair of the dog that bit him." In short, as his profession does not exercise his intellect at all, he cannot fail to indulge in what he thinks his only pleasure. Let us suppose this to be continued until he reaches man's years, when the effect will be seen in an intellect, blunted, and quite useless from inaction. For we know well, that the thinking, like the physical, part of the man, is either perfectly or imperfectly developed—by proper or improper exercise. This man's brain is unexercised, nay, it is diseased; he has acquired a sensual and ungovernable appetite for the drug that enfeebled, and still continues to enfeeble, both his mind and body, and he is in such a morbid state, that all his efforts to reform or improve his mind are ineffectual. He tries *Mechanics' Institutions*, and all the other schemes for improving the working classes, but to no purpose; his mind, from want of habit, cannot follow the lecturer; he gets inattentive—sleeps—and loses the thread of the subject; repeats his visits for a night or two, perhaps, and the lectures get to him "the longer the drier," until he quits in disgust, what might, under other circumstances, have been a source of enjoyment to him. When such a character

enters into the solemn engagements of matrimony, his previous habits and badly regulated mind ill qualify him for the various duties of husband or father; he brings into the world a few squalid, degenerated wretches, and by his brutal conduct, drives his well-disposed partner to that temple of infamy the gin-shop, for the melancholy purpose of "drowning her cares." I will not disgust the reader by dwelling upon the united effects of their example on their thus hereditarily vicious offspring. The wretched man continues to work and drink alternately, until he reaches the workhouse if in England, and beggary and crime if in Scotland: a poor grumbling, discontented, shameless pauper, both unable and unwilling to work; for the man who has spent twenty years of his life sharpening pin-points, or guiding a self-acting turning machine, has not physical strength to handle a spade or road hammer, even if he had not been previously wasted by dissipation. This is not an exaggerated picture; the melancholy details of evidence brought before the Factory Commission furnish multitudes of such instances. It is not the long hours, however, that is the sole cause of this evil I maintain: it is the division of labor that is the root of the evil, which I shall endeavor to illustrate by another example, *not ideal*, but like the former, *real*: and the writer has many characters under his own eye, of both kinds, to choose from.

In Scotland, some ten or twelve years ago, the division of labor was not (and is not even now) carried to the extent that it is in England, and consequently the working classes have a higher moral character, which is commonly ascribed to education, and a modern training. This is the case in a very few instances; by far the greater number of the Scotch mechanics and operatives receive a very limited education. When they are sent off to a trade, they can half read, and perhaps make shift to write the letters of their own name—but the difference rests here; the Scotch mechanic has to do a great variety of jobs, not one of which he can do so quickly as the expert Englishman.

As an instance: About twelve or fourteen years ago, an engine-maker had to learn to make a tolerable good pattern; he had to turn both iron and wood, to fit up, put together, and attach the engine to the factory; he had thoroughly to understand drawings, and in many cases had to draw himself. The reader will readily imagine, that this must be a clumsy "Jack of all trades": this is not the case however,—he is a slow, but a good workman. Suppose exactly such a boy as we took in the former case, bound apprentice to this trade for seven years: for one year he is allowed to run loose about the work, he is every "body's body," runs messages, creeps into holes to do jobs which men cannot reach. By the end of the year, he has acquired a very rude general notion of the whole work, but can do little or nothing with his hands. He is now stationed at a bench, and from making simple articles, comes on with great satisfaction to himself to make good patterns; he then wearies, because he thinks himself master of the subject; having little mental work to perform, he is now in great danger of going astray, but happily for himself he is shifted to another department, upon which he enters with great spirit, and feels with intense delight, as bit by bit he masters the various tasks put before him. His brain thus stimulated and exercised, a thirst for knowledge is created, and he is driven in search of food for his

mind to a Mechanics' Institution, where he hears and sees, for the first time, the astonishing fact, that the water he drinks is composed of two gases that burn. This leads him to endeavor to read, that he may learn more of the matter, but he finds he cannot do it so quickly as he would like; he then sets to work with good will, goes to an evening-school, and his mind being in an excellent state for receiving instruction, he makes most rapid progress. I need not trace him farther—here is a useful and promising member of society, who himself enjoys life and all its blessings. A few such (according to the strength of their intellect) turn out eminent men—the rest are scattered over the earth in the shape of managers, superintendents, and foremen, of flourishing works; and it is worthy of remark, that in all the large manufacturing towns in England you find a large proportion of Scotchmen doing the intellectual work of large mechanical establishments. This does not arise (as Sandy's vanity always suggests) from a "national superiority." John's head is just as good as his, as is seen in every case where there has been the same chance of getting the organs developed. I regret to state that the baneful system of dividing labor is fast spreading in Scotland, and the moral degradation attending it cannot be denied by the most ardent admirers of the religion and morality of that country. It must not be supposed that the character I have last attempted to describe has been exempt from temptation. No, he has kept company with the drunken and the dissolute (of which there must be a large proportion in every society;) but his mind having been properly set to work, he soon calculated the amount of real pleasure or pain to be derived from seeking after knowledge, or from a course of profligacy. Nor must I be understood as assuming that all are depraved who labor at one particular object all their lives, for there are some minds that naturally resist the influence of such causes; but the number of the good bears a small proportion to the bad in countries where this vicious system is carried to great extent. There is another demoralising effect yet to be noticed, which I shall endeavor to do as briefly as possible. An improvement in machinery often turns hundreds adrift upon society, who having spent the best part of their lives in some such trifling work as heading pins, are too old to learn another business, and for reasons already mentioned they cannot do out-door work; their minds being untutored, they do not make a very vigorous effort to do their best at a new job, well knowing that they will not be allowed to starve in England. In many, very many cases, such men direct their blind rage to the breaking of machinery, not only the machine which superseded them, but machinery of all kinds; in short, a large proportion of the seditious, the incendiaries, the swinge, machine-breakers, &c. which disturb the peace of society, are division-of-labor people, thrown out of work, and who have neither physical nor mental strength left to turn themselves to another decent employment, seeing that the few that do so are scarcely fit to earn sufficient to support a miserable existence.

It is common enough to hear the *lordly* aristocrat, or wealthy man of business, express their *disgust* in such unmeasured terms, as the "beastly multitude," the "canaille," the "scum of the earth," &c., and grumble loudly at the overwhelming poor-rates. Let them examine themselves carefully, and see that they be not aiders and abettors of such infamy. Let them re-

member, that the cause of this evil is *over-taxation* (and every one, who directly, or indirectly, robs the public purse, is to blame for perpetuating the evil,) and not turn away in disgust from his fellow-being whom he has already injured.

We take some trouble to educate the lower animals, and if some of these our humble servants are not so tractable as could be wished, we do not vent our anger upon them, but upon their trainers. Why, then, should the higher classes *spurn* the poor, misled, untrained mechanic, whose labor has perhaps enriched them? It were a wiser course, and a way to root out the evil, were they to set on foot a proper plan of national education, inquire into, and amend, some of the absurd apprentice-laws, and put the rising generation in the way of acquiring more than one branch of a business, in order that their minds may be so far exercised as to make them good members of society, instead of converting them into *mere machines* for the acquisition of wealth. We see the good effects produced in the middle classes by education. Why, then, should a large proportion of our fellow-creatures be allowed, or rather doomed, to remain in a state of darkness? I trust these remarks will be followed out by some of your abler correspondents at some future period. I am afraid I have already occupied too much of your valuable space. L.

May 4, 1835.

FRANKLIN INSTITUTE.—The seventh conversation meeting of the Institute, for the season, was held at their Hall April 23d, 1835.

Mr. Thomas Ewbank, of New-York, exhibited a series of experiments on the rarefaction produced in the air within a tube, by blowing through another tube inserted into the first; the tubes were variously connected, and proportioned in dimensions, and the degree of rarefaction produced in each was measured by the rise of a column of water into the tube.

Mr. Ewbank showed that this principle might be applied conveniently to syphons, the flow of water through them being commenced by blowing through a lateral tube. He also exhibited a syphon, the shorter leg of which terminated in a tube, widening as it receded from the bend, and which was filled by stopping the longer leg with the syphon, and immersing the other leg of the syphon in a liquid; on the removal of the finger, the momentum of the liquid carried it up the shorter leg, passing the bend.

Messrs. Lehman & Duval, of Philadelphia, exhibited various specimens of lithography, drawn and printed at their establishment.

Professor W. R. Johnson showed an apparatus intended to illustrate the principle upon which rockets ascend, and to show that such ascent might take place in vacuo, and, therefore, could not be produced by the re-action of the gas, issuing from the rocket upon the air without. The apparatus consisted of two revolving arms, with opposite apertures, like those of Barker's mill; this was placed in an exhausted receiver, and set in motion by admitting air through the apertures into the receiver. The arms were furnished with broad wings, presenting a large surface to resist the motion through air. The velocity was perceived to be greater as the vacuum was more perfect.

THE COMET.—We understand that Professor Anderson, of Columbia College, has seen the comet several times, and traced its path.

[From the Scientific Tracts.]

A LETTER TO DR. FRANKLIN, BY A SEAMAN, MANY YEARS AGO.—I have often wished that somebody would carefully collate a sufficient number of meteorological journals, with intent to observe and class the several appearances in the atmosphere before great changes in the weather, particularly before great storms. I am persuaded, from my own observation, that, in general, sufficient indications of impending tempests precede them a considerable time, did we but carefully note them.

The phenomenon which I am going to mention, is one of those indications which not only portend an approaching tempest, but ascertain from what quarter it will come: a circumstance that may render it of essential service to seamen. I believe the observation is new, that the aurora borealis is constantly succeeded by hard southerly or south-west winds, attended with hazy weather, and small rain. I think I am warranted from experience to say, constantly; for in twenty-three instances that have occurred since I first made the observation, it has invariably obtained. However, I beg leave to request that you will recommend it to the notice of the Royal Society, as a matter which, when confirmed by further observations, and generally known, may be of more consequence than at first appears. To show that it may, give me leave to recite the circumstance which first occasioned my taking notice of it. Sailing down the English Channel in 1769, a few days before the autumnal equinox, we had a remarkably bright and vivid aurora the whole night. In shore, the wind fluctuating between N. N. W. and N. W., and farther out W. N. W.; desirous of benefiting by the land wind, and also of taking advantage of an earlier ebb tide, I dispensed with the good old marine adage, "Never to approach too near a weather-shore, lest it should prove a lee shore," and by short tacks clung close along the English coast. Next day the wind veered to the S. W., and soon after to S. S. W. and sometimes W. We were then in that dangerous bay between Portland and the Start Point, and carried a pressing sail, with hopes of reaching Torbay before dark; but night came on, with thick haze and small rain, insomuch that we could not have seen the land at the distance of a ship's length. The gale was now increased to a storm: in this dilemma nothing remained but to endeavor to keep off the shore till the wind should change. Luckily, our ship was a stout one, and well rigged.

Reflecting, some time after, on the circumstances of this storm, and the phenomena that preceded it, I determined to have particular attention to future auroræ, and the weather that should succeed them; and, as I observed above, in twenty-three instances have found them uniform, except in degree; the gale generally commencing between twenty-four and thirty hours after the first appearance of the auroræ. More time and observation will probably discover whether the

strength of the succeeding gale is proportionate to the splendor and vivacity of the aurora, and the distance of time between them. I only suspect that the more brilliant and active the first is, the sooner will the latter occur, be more violent, but of shorter duration, than when the light is languid and dull. Perhaps, too, the color of the aurora may be some guide in forming a judgment of the coming gale. That which preceded the storm I have mentioned, was exceedingly splendid. The tempest succeeded it in less than twenty-four hours, was violent, but of short continuance. In June last, a little without soundings, we had for two nights following faint inactive auroræ; the consequent gale was not hard, but lasted nearly three days; the first day attended with haze and small rain, the second with haze only, and the last day clear.

The benefit which this observation on the aurora borealis, when further confirmed, may be to seamen, is obvious, in navigating near coasts which extend east and west, particularly in the British Channel. They may, when warned by this phenomenon, get into port, and evade the impending storm; or, by stretching to the southward, facilitate their passage by that very storm which might otherwise have destroyed them; for no winds are so dangerous in the Channel as the southerly and south-west. In a word, since I have made this observation, I have got out of the Channel, when other men, as alert, and in faster sailing ships, but unapprized of this circumstance, have not only been driven back, but with difficulty have escaped shipwreck.

Perhaps the observation, that southerly gales constantly succeed these phenomena, may help to account for the nature of aurora borealis. My own thoughts on that subject I shall sometime beg leave to lay before you. J. S. WINN.

[From the same.]

CONTACT OF COMETS.—In the course of a lecture on comets, delivered at the Royal Institution, by Dr. Lardner, on Friday evening, the 1st of May, the lecturer took occasion to allude to a report which has been going the rounds of the newspapers, purporting to come from Sir John Herschel, to the effect that Halley's comet, which is expected to make its appearance in the course of the present year, had long since changed its course, and now revolved in another orbit. Dr. L. observed, that Sir J. Herschel had not any means of ascertaining such a change, other than those possessed by any other astronomer; and he was of opinion that the paragraph was either a fiction, or else greatly exaggerated, exemplifying the story of the three black crows. There are only two circumstances from the occurrence of which the orbit of a comet can be changed. In its course it may meet with a planet, the attraction of which may be sufficient to produce such an alteration, or it may cross the path of another comet, and either coalesce with it, or be acted on so as to produce that effect. Sir J. Herschel, however, has no

means of ascertaining that either of these circumstances has occurred in the present instance, and Dr. L. sees no reason to doubt that the comet will make its appearance.

In the course of the lecture, Dr. Lardner mentioned a curious fact relating to the splendid comet which appeared in June 1770, and was observed by Messier, surnamed by Louis XIV. the *comet ferret*. It passed within the orbit of Jupiter, and was visible in an unusually large part of its course, which was very carefully observed and noted. Messier not being a mathematician, Lexon computed the observations, and laid down its path. He at first considered its course was a parabola, but not being able to compute it correctly according to that supposition, he examined further and ascertained that its orbit was an ellipse, and its course would be completed in about five years and a half. Considerable attention was excited on this occasion, and its re-appearance anxiously looked for; the time passed, however, and the comet did not make its appearance, nor could any account of any previous visit be discovered.

This fact proved a complete problem until Laplace grappled with it; and he ascertained by accurate investigation, that this comet, of 1770, during its course, on the 18th of January, 1767, at noon, came in contact with the planet Jupiter, and remained entangled for about six months. Previous to this it described an orbit of fifty years, but the new orbit in which it revolved after its contact with Jupiter, was one of five years and a half. In this manner Laplace accounted for its non-appearance previous to 1770, inasmuch as previous to that date its path was so distant as to render it invisible. The explanation given for its non-recurrence was equally feasible. Jupiter runs its course in eleven years, and this comet in its new orbit completed its revolution in five and a half. At the end, therefore, of the first five years and a half, the planet Jupiter being then at a great distance, the comet should have been seen, but it so happened that at that time the earth was in such a position with regard to the sun, as to render it invisible. When the period approached for the completion of its second revolution, it was again met by the planet Jupiter, and again its orbit was changed. The ellipse into which it was thrown this time was one of 20 years, and its path was so distant as to render it again invisible.

From Charleston, by the steamboat, we have papers of Saturday afternoon. The Patriot of that day has this article respecting the *Stranger's fever*, or, as called here and elsewhere, the *Yellow fever*, which has broken out in that city:

HEALTH OF THE CITY.—It will be perceived from the Report of the Board of Health, that there have occurred but seven deaths from the *Stranger's Fever*, from the 17th of August to the 7th instant. This is a very small number for the season in which this form of disease usually prevails in our city, and we understand that such is the mild character of the prevailing fever, that it is perfectly manageable with care and skilful treatment, as is always the case when it appears after the middle of August.

[From the Apprentice's Companion.]

The following excellent article on Female Education is from the "American Annals of Education"; and, although it is not addressed to "Apprentices," it may be of use to them to know how to select—for most of you will probably desire to select, when in a situation, a companion for life.

A mechanic, above all other men, ought to have an industrious, prudent, and economical wife—she should not only know how to govern her family, but also to govern herself. She, above all women, should feel and know that home, rather than the streets and neighbors, is her proper place. If therefore you would have such a companion, seek not for her where the mother is a fashionable, or one who spends more time from, than at, home.

#### FEMALE EDUCATION.

**Domestic Habits.**—In advising as to the course of early female education, I have insisted on the necessity of cultivating, in childhood, the habits of Temperance, Order, Activity, Industry, and Self-command, as essential to the health, happiness, and usefulness of woman.

There is another branch of female education of the first importance which involves many particulars, but may be termed the preparation for domestic life. This involves both habit and skill in domestic employments.

We must begin with forming domestic habits. No quality is more essential to the dignity of the female character; and without it there will never be patience in the acquisition of domestic skill. On the other hand, the domestic disposition is best cultivated by giving domestic employments. Useless objects and occupations soon tire us. Splendid furniture and ornaments, and mere amusements, produce a weariness, from which there is no escape, but by perpetual change. On this plan, how many families are made, not automations, unfortunately, but locomotives, active only in vain and mischievous efforts for "some new things." As capable of happiness as their neighbors, they have never learned the true mode of enjoying it. They promenade the streets; they wander from shop to shop, from house to house, from street to street, gathering every subject for vanity or trifling, every secret or witticism, or report, they can find, to enlarge their supply of occupation for idle hours. Such "busy-bodies" always leave their own duties, undone, or ill-done; and the habit of neglecting their own concerns necessarily leads them to occupy themselves with the affairs of others, and to interrupt them in their occupations, or interfere with their peace.

Let the daughter then be guarded against this pernicious fault. Let her be trained to feel, that her first great duty, when not engaged in the acquisition of useful knowledge, is at home—that she is her mother's natural assistant or substitute, in the care of the nursery, and the family. When she has well-learned the lesson of obedience and self-command, she may safely be entrusted with the direction of the other children, but not till then. Under the direction of her mother, she may, in this way, complete her course of training in self-government, and learn to imitate her heavenly father, who is "kind even to the evil and unthankful."

But she must also learn in the nursery

that peculiar duty of woman,—the care of the feeble and the sick. Every family, and every child, are every day liable to accident and disease. Nothing in the nursery is so important as habitual care to prevent disease, and to relieve pain, or remove the cause at once, when it occurs. More can be accomplished to secure the health of children by the faithful, interested nurse, always present, than by the absent physician, however skillful, in occasional visits, which often prove too late to remedy the evil. This office, the elder sisters, and each of them, as they grow up, should be taught and accustomed to fill. For this purpose, she must acquire, not merely skill in watching and providing for the wants of her charge: presence of mind, gentleness of disposition, combined with firmness of resolution, are indispensable to the good nurse. These must, therefore, be cultivated and matured by constant practice. Daughters who are not trained in this manner can never be safely entrusted with the health of a family. Poor and pitiable matrons—still poorer and more pitiable, their companions, and their families!

But the nursery is not the only place for domestic duties and skill. Humble as the theme is, we cannot complete our view of female education without descending to the kitchen; for the table of the king himself must be furnished from it, and even the health of the family depends upon its right management. Order, and skill, and vigilance, must begin there, or comfort can never inhabit the house. She who governs it must learn in the only way possible—by acquiring practical skill in all that is to be done. This is an every-day business, not to be accomplished by one great effort, or by some wonderful plan, but by the regular, returning care of a directing eye, and a skillful hand. The mistress of a house becomes a pitiable cypher, if she has not the practical knowledge to direct the when, and the where, and the how, of every thing that concerns her family affairs; and she can learn this only by experience. Respect is paid to authority, only when those who exert it know how to give directions in the right time, and the right manner.

Let the daughter, then, as much as possible, learn every part of household duty, practically. It was a wise step in a circle of ladies in one of our cities, to finish the education of their daughters in a cookery school. They attended punctually, and daily, for a certain number of hours, long enough to give them a competent and practical knowledge of the arts and the economy of the kitchen. Their works praised them; and the convenience and pleasure of a well regulated, economical, and healthy table was the reward of their efforts. Regularity and order prevailed in every department of the house, because the whole was directed with intelligence and skill. The incessant causes of scolding, and fretfulness, and discontent, were in a great measure removed, by the training which not only gave these matrons habits of industry and self-command for themselves, but taught them how to direct the employments of others with regularity and success.

In visiting the house of Mrs. —, every one is ready to ask, "How could you bring your family to this regular, quiet, pleasant state?" The simple answer is, "by understanding what every one ought to do, and how it ought to be done, by beginning right and persevering in the right course, until every one knew her duties, and could do them well." A course of actions will form a habit; and habit, we know, is second nature. In this way, hard

things become easy, and labor pleasant. Idleness will be at length painful, and fretfulness intolerable. It will be easier to do right, than to resist the steady current of order in the family; and every disturber of the peace will be frowned upon, as an enemy of the whole.

And while I am urging this duty, I cannot help alluding to the sad neglect of it in modern days. What is to be the history of the rising generation? Must it be told in language like this?

"Fashion and accomplishments, and amusements, and unnecessary display in literature and science, absorbed the whole time of the females of this period. Domestic cares and virtue seem to have descended to the tomb with their grandames, or to be consigned with their pictures to the garret. Their domestic skill was lost, and their domestic habits forgotten or despised; and when the tale was told by some relic of former days, or appealed to as an example, it was only met with a suppressed smile at such antiquated notions, or an open scoff at those who busied themselves at home in ignorance, or submitted to be slaves to their husbands and children. The immediate consequences were such as might be anticipated. The wealth which industry abroad and frugality at home had accumulated, was scattered by indolence and ignorance, and prodigal expense. The noble dwellings which it had raised and furnished, were sold to pay the debts of extravagance, or pulled down to make way for others, which soon shared the same fate. Many a mechanic, who grew rich by the obsolete virtues of industry and economy, occupied the splendid house of those who looked down upon him, and despised his virtues; and his daughters held the first station in society, while those of his employer might be found in some obscure corner, with little to cover them but worn-out finery, and apparently with little to sustain them but their pride in what they had been. Nay, the domestic was often to be seen taking the place of his master, and occupying the station from which his children had fallen, by the neglect of forming domestic and industrious habits in their education."

Whether this shall be the record of the whole generation or not, such is, unhappily, the history of many a family, and is likely to be that of many more. Perhaps I shall not even obtain a hearing from those who have already begun this course. The whirlpool seldom permits any to escape who have once entered, even its margin. But those who are approaching it may, perhaps, hear me; and I warn them, that they guard against its powerful current before it is too late; for I have witnessed more examples than I can mention, of its ruinous effects.

I am aware that economy and its attendant train of minor virtues are old fashioned matters. They are found in here and there a family; but the very names seem rather to belong to the dictionaries of the last century. But there is a section in an old book, too seldom studied—the last counsel of a wise man—which recommends them; and as it describes particularly the virtues and the defects of women, it ought to be often read by mothers and daughters. Although not new, its very antiquity, I trust, will give it authority with most readers; and in addition to other salutary truths, they will learn that in female education, and in female duties above all things, "the fear of God is the beginning of wisdom." SENEX.

NEW-YORK AMERICAN.

SEPTEMBER 12—18, 1835.

EUROPEAN INTELLIGENCE.

**LATEST FROM EUROPE.**—By the packet ship United States from Liverpool, London papers to the 8th ultimo inclusive are received. Ours not having come to hand as yet, we are indebted to the office of the Gazette for the latest papers.

In England, the main topic is the Municipal Corporation Bill, under discussion in the Lords, where it was apprehended it might be thrown out—such apprehension, the Times however, pronounces unfounded.

The Paris papers of the 6th are filled with details of the funeral of the victims of the attempt to assassinate the King. We extract from Galignani a full account. Great care was taken to arrange the line of march, so that the royal family, in attending the procession, should not pass within shot of any dwelling. The gardens of the Tuilleries, through which they passed to join the procession on the *Place Louis XV*, were cleared of all visitors, and thence to the *Invalides*, the only building to be approached near by was the Hall of the Deputies. On the day succeeding the funeral the royal family went to return thanks at *Notre Dame*, for their escape from assassination. As that church is in the heart of the *Cité*, (the island so called,) and only approachable through narrow and densely populated streets, the royal family went in close carriages, strongly escorted by a detachment of lancers, and proceeding at full gallop. No accident of any sort occurred, and the royal family returned in safety.

In the sitting of the Chamber, M. Parail, after a prefatory speech from the Duke de Broglie, developed the new measures for restricting the press. A full report of them will be found below.

To publish anything offensive to the King, or attacking the principle or form of his government, is declared an *attentat*, or treasonable attempt against the State, and becomes thereby liable to be brought before the Court of Peers. The penalty may be perpetual imprisonment, and a fine of 2,000*l.* sterling. To deride the King or his authority may be punished with from six months to five years imprisonment, and with from 20*l.* to 400*l.* fine. The public declaration of Carlist or Republicanism is punished similarly with the last offence.

Every *gerant*, or responsible editor must, on being questioned, divulge the name of the author of any article. He must insert any answer or contradiction which the Government may think fit. He cannot be responsible editor after condemnation.—For infraction of these laws he is amenable, not to the Jury, but to the Correctional Police. The censorship is re-established for prints, lithographic emblems, and theatrical pieces.

The vote of the jury is to be secret; and the names of jurymen are not to be published by any journal. The verdict is returned by a bare majority; viz., of seven votes.

A person condemned to deportation may be sent to any house of detention beyond the limits of France. This clause is introduced for those about to be condemned by the Court of Peers, who will probably be sent to the African coast. The final judgment of the Lyons prisoners is expected in the course of the ensuing week. Notwithstanding rumors to the contrary, no sentence has yet been passed.

TEXT OF THE BILL.

"CHAP. I. Crimes, Offences, and Misdemeanors, by means of the Press, or any other mode of Publication.

"ART. 1. Every offence against the person of the King, whether by one of the means mentioned in article 1 of the Law of 17th May, 1819, or any other mode of publication, is an attempt against the safety of the State. Whoever shall be found guilty of the same, shall be punished with detention, and a fine varying from 10,000 francs to 50,000 francs.

"ART. 2. Whoever shall by the same means have endeavored to turn into ridicule the person and authority of the King, shall be condemned to

imprisonment for a term varying from six months to five years, and to a fine varying from 500 to 10,000 francs. The offender shall, moreover, be deprived of the whole or part of the rights mentioned in Article 42 of the penal code, for the entire duration of his penalty, and for a term equal to that of the imprisonment to which he may have been condemned.

"ART. 3. In discussing the acts of Government, it is forbidden to introduce the name of the King, either directly, indirectly, or by allusion. The author of an offence herein shall be punished with imprisonment, for a term varying from one month to one year, and with a fine varying from 500 to 5,000 francs.

"ART. 4. Any attack by one of the same means against the principle and the form of the King's Government, as established by the constitutional charter of 1830; any direct or indirect provocation to change them, is an attempt against the safety of the State. Whoever shall be found guilty of it shall be punished with detention, and a fine varying from 10,000 to 50,000 francs.

"ART. 5. Whoever shall have publicly manifested his adhesion to another form of government, either by assuming the qualification of a Republican, or by expressing a wish, hope, or threat, for the destruction of the monarchical or constitutional order, shall be condemned to imprisonment for a term varying from six months to five years, and to a fine varying from 500*fr.* to 10,000*fr.*

"ART. 6. Whoever shall have publicly attributed the right to the throne of France, either to one of the Members of the family condemned to perpetual exile by the law of the 10th April, 1832, or to any other than Louis Philippe I. and his descendants; whoever shall have expressed a wish, hope, or threat for the restoration of the fallen Government, shall be condemned to imprisonment for a term varying from six months to five years, and to a fine varying from 500*fr.* to 10,000*fr.*"

The Minister of War proposed to the Chamber, amid unanimous acclamations, a pension of 20,000*fr.* to the widow of Marshal Mortier, with reversion to her son—of 6,000*fr.* to the widow of Gen. Verigny, with reversion to her children—of 3,000*fr.* to the mother of Captain Villatte—and of 3,000*fr.*, in addition to his half pay, to Gen. Blin, the only one of the four officers named, who survived his wounds.

M. Carrel, and other editors who had been arrested in the first ebullition of resentment, had been liberated after an insignificant interrogatory.

Gerard the assassin, or, as his name is now ascertained to be, *Fieschi*, was recovering from the effects of his wounds. Nothing has been discovered to inculpate, or connect, others in the attempted assassination.

[From Galignani's Messenger.]

**FUNERAL OF THE VICTIMS OF JULY 28.**—The sad solemnity by which it was intended to close the fatal and deplorable tragedy that so cruelly interrupted the rejoicings of last week, being appointed for yesterday—the day fixed upon for the interment of the murdered victims—every part of the metropolis began at a very early hour in the morning to display the bustle of preparation for the melancholy ceremony. Crowds were seen pressing from all quarters to every point which promised to command a view of the mournful procession, while numerous groups of General Officers, National guards, and detachments of the line, were encountered, crossing each other in every direction, hastening to the post assigned them in the performance of the solemn duties of the day. The National Guards were in immense force—not only those of the capital, but corps from all the towns, villages, and hamlets in the environs, were in attendance; some had even sent detachments from a distance of upwards of 30 miles. These brave citizen troops, always the firmest friends of public order, and never backward when their services are really required seem to have felt the necessity of manifesting their detestation of the late atrocious crime, and its abettors, should any such monsters exist, by this significant expression of their sympathy with the sufferers.

The shops of the capital were, with scarcely an exception, entirely closed, not only in the line of the procession, but in the remotest parts of the town; fine, nothing was omitted which could mark a respectful sympathy of the public at large

with the sorrowful occasion. The line of the Boulevards was, as usual, the great point of attraction, and their entire extent, from the Place de la Bastille to the Church of the Madeleine, was crowded with spectators; balconies, windows, trees, and temporary stands, wherever accommodation could be afforded, or a human form be placed, not a spot was untenanted by an anxious though a silent gazer upon the solemnly gorgeous pageant. At precisely half-past 8, the remains of each victim was removed from the *chapelle ardente* in the church of St. Paul, where they had lain in state since Saturday last, and placed in their respective hearses. This task being completed, the sad procession moved onward. Three mourning coaches, in which were the clergy of the church of St. Paul, preceded the first hearse, in which was the body of Mademoiselle Remy, who met her untimely fate at the age of 14. The effect of this simple bier was most touching; it was ornamented with entire white draperies, and drawn by two beautiful snow-white horses; twelve young girls, veiled, and also dressed in white, attended as pall-bearers, and the remains were followed by the relatives and friends of the deceased.

At the moment the procession first advanced the awful silence created by the sight upon the thousands, or rather hundreds of thousands, who crowded every dwelling from the roof to the pavement, in the populous rue St. Antoine, and the visible expression of sorrow in every countenance, was a sublime protest on the part of the people against the base and cowardly assassination which had hurried so many victims to a bloody and untimely grave. The next hearses in succession were those of M. Labrousse, receiver of taxes of the 7th arrondissement; M. Brunot and M. Ingland, spinners of yarn; and M. Ardouin, a workman. Next came those of Messrs. Benester, Leger, and Ricard, grenadiers of the 8th Legion of the National Guards, and M. Prudhomme, sergeant of the same Legion. The pall-bearers were their comrades of the 8th Legion.

The pall-bearers of Captain Villatte were officers of the army; those of Colonel Raffé, officers of the Municipal Guards and the departmental Gendarmerie; those of Colonel Rieussee, of the 8th Legion, were four officers of the National Guards; those of Major-General Delachasse de Verigny, four superior officers of the army; and those of Marshal Mortier were Marshals Grouchy, Gerard, and Molitor, and Admiral Duperré. All the hearses of the military men were surrounded by tricolored flags and military emblems, and became gradually more handsome according to their rank. The horses of the last five, each led by two grooms, followed their respective masters, the first four being covered with black crape and white fringe, and that of Marshal Mortier with crape powdered with silver stars, and edged with silver fringe. The pall on each coffin bore an escutcheon with the initials of the deceased; that of M. de Verigny was surmounted by a coronet. The hearse which covered the remains of Marshal Mortier was, of course, as becoming the princely rank of the deceased, of a much more magnificent description than the others. It would, in truth, be difficult to conceive a funeral car of construction at once so richly gorgeous in its effect, and yet so solemnly appropriate to its melancholy purpose. Four large allegorical figures in silver raised upon a massive ornament of the same metal, the whole surrounded by a silver casque with rich sable plumes, composed the crown of the car, each corner of which was formed of a female figure, emblematic, as were those of the central superior ornament, of the Christian virtues. These figures, also in silver, were likewise each surmounted by a casque and large sable plumes.

Several tricolored flags were placed at various points of the vehicle. On the pall which covered the coffin, and on which the dual arms and coronet of the deceased were embroidered, lay his armed robe with other insignia of his rank, among which the well-worn sword of the gallant veteran, was the most touchingly conspicuous. The car was followed by the members of his afflicted family and a concourse of private friends. On arriving at the Place de la Bastille, where tents had been raised for the accommodation of the ministers and the various deputations from public bodies who were to join the procession at that spot, some delay and irregularity took place, but the necessary arrangements being soon made, the march recommenced, and proceeded along the Boulevards without interruption or accident. After the public bodies, followed the Polytechnic School, and deputa-

tions from the *décors* of July, workmen and laborers. The porters of the wharf of La Rapée bore a large willow branch covered with crape and surmounted by wreaths of everlasting, and a flag with the inscription—*Vive la Charte! Vive la Liberté! Port de la Rapée! On another—Les Ouvriers des Ports.*

As the hearse passed the fatal spot where the assassinations were perpetrated, the emotions of the mourners were most painfully apparent. The window at which the truly-named *machine infernale* was placed has been blocked up, but two women (respectable as far as dress is concerned) boldly sat at the window beneath, quite unabashed by the gaze of the thousands turned upon them. The Boulevards offer nothing further to remark upon, except that upon any less melancholy occasion, the crowds of beauty and rank which thronged every window and balcony, the admirable order and appearance of the National Guards and troops, and the animated nature of the entire scene, would have rendered it a sight so gratifying as never to be forgotten. We now turn to the part of the ceremony in which His Majesty and the Royal Family bore a part. The King, with the Dukes of Orleans and Nemours, and the Prince de Joinville, left the Tuileries on horseback precisely at 11 o'clock, and notwithstanding the great interest necessarily attached to a sight of the funeral pageant, immense crowds awaited His Majesty leaving the Palace, and the bridge, quay, and every part of the town through which he was to pass with his family in their way to the Invalides. His reception was more than enthusiastic—so cheering that it was easy to perceive that the *sang froid* and manly indifference, he last week displayed in the moment of extremest danger, was more than once overthrown by the touching marks of affection and loyalty with which he and the Royal Family were received.—His Majesty looked calm and well, as did the Duke of Orleans and his brothers; but we regretted to see that the cruel event of Tuesday had left deep traces of grief and apprehension on the features of Queen and the Princesses.

At about half-past 11 o'clock, the Queen and the Princesses, who were in deep mourning, reached the Church in the Invalides; and in a few minutes His Majesty also arrived accompanied by the Dukes of Orleans and Nemours, and the Prince de Joinville, and escorted by his staff. Long before the appearance of the Royal party, the countenance of the auditory admitted to view the ceremony with tickets, betrayed a degree of anxious expectation, which was heightened not only by the solemnity of the occasion itself, but by a natural and loyal feeling of impatience for the presence of the Sovereign, whose existence scarcely more than eight days before, had been so miraculously preserved. This feeling was evinced at intervals by the deepest silence, interrupted only by the firing of the minute guns, which announced his Majesty's progress along the line, followed by the procession.—The King entered by the gate on the side of the Place Vauban, which he reached by means of a bridge thrown across the Fosse. On entering under the dome, he made a turn to the right, and passed before the Peers, by whom he was received with reiterated acclamations of *Vive le Roi!* which were re-echoed by the Deputies seated on the left.

His Majesty then passed before the *Corps Diplomatique*, by the members of which he was respectfully and cordially saluted as he proceeded towards the throne which had been prepared for him near the altar. After a short stay in the church, their Majesties retired into a separate part of the building which had been prepared for their reception.—The deputations from the Courts, the Tribunals, the Institute, &c., occupied that part of the *pourtour* of the dome, which remained vacant after the Deputies and the members of the *Corps Diplomatique* had taken their places. The estrade, which had been disposed under the dome for the reception of the bodies, was decorated with the most tasteful magnificence and brilliantly illuminated, and indeed the whole of the arrangements made in the building of the Invalides were most judicious, and perfectly in unison with the solemnity of the day. Each side of the avenue leading from the gate to the front of the edifice was ornamented with a succession of obelisks hung with black, and connected together with cypress garlands and tricolored flags. The *pourtour* of the Court of Honor was hung with black draperies. The *coup d'aix* presented by the church was most imposing. From the centre of each arch

in the grand nave enormous draperies were suspended. All the windows were hung with black to the top, and received no light whatever from the outside.

Each arcade was lighted by a lustre. The pillars and pilasters near the principal altar were covered over with black crape and velvet, and between the principal altar and the dome to the left, a sort of low estrade had been arranged with seats, cushions, and black velvet *prie diés*, trimmed with silver, for the accommodation of the King and the Royal Family. Under the dome had been arranged an immense square estrade with fourteen cenotaphs, all disposed at the same point of elevation, and surrounded by a rich canopy of colossal proportions. The architectural ornaments of the dome were veiled by sable draperies, which extended to the height of the galleries, and completely excluded all external light. At the base of the vast catafalque, to which we have just referred, were several enormous candelabra, whilst the upper part of it was covered with innumerable wax tapers, the whole being illuminated from above by four large sepulchral lamps, and a quantity of lustres and chandeliers. The name of each of the victims of the atrocious attempt of the 28th was inscribed in letters of silver on each of the sides of the catafalque, around which were stationed a detachment of the 7th Legion of the National Guards and some troops of the line.

At half-past 1 o'clock the arrival of the funeral procession was announced to His Majesty, who immediately passed through the nave, and was again received with the warmest and most enthusiastic acclamations by the assembled crowd, a large proportion of whom were ladies. The biers were placed in succession on the estrade; this part of the ceremony, in which the entire of the 14 murdered victims were brought together under the eyes of the Royal Family and the whole assembly, produced an impression of the most awful nature, and hundreds of the spectators were unable to control their emotion. At half-past 2 o'clock the Archbishop of Paris, and a number of the clergy, ascended the altar, and chanted the magnificent service of the dead, by Cherubini. The funeral oration, which produced a deep impression, was delivered by the Abbé Landrien. The Rev. orator dwelt on the noble and brilliant actions which marked the military career of the gallant but ill-fated Marshal Mortier, and concluded by paying an eloquent and feeling tribute of respect to the memory of his fellow victim. The last prayers for the dead having been recited, the *De Profundis* was chanted with a degree of sublimity, of which the auditory testified their admiration by their breathless silence.

The funeral ceremony terminated at about half past 4 o'clock, and at that hour the King and Royal Family quitted the church, His Majesty and the Princes on horseback, and a few minutes before the Queen and Princesses. The departure of their Majesties was announced by a salvo of twenty-one guns. The King, accompanied by the Princes, and attended likewise by his brilliant and numerous staff, then inspected the ranks of the National Guard and the troops of the line mustered in review order on the Esplanade of the Invalides, the Quai d'Orsay, and finally in the garden of the Tuileries, and after meeting on every point with the most devoted and unaffected expression of loyalty and attachment, their Majesties and the Royal Family returned to the Palace of the Tuileries at a few minutes past 6.

Reviewing the solemnity of yesterday, looking to the zealous attendance of the National Guards not only of Paris, but of the vicinity, which alone, we should believe, amounted to upwards of 60,000 men, and the reception of the King by that class who form emphatically the people—coupling with these demonstrations the spontaneous expression of horror and indignation at the crime heard from the remotest quarters of France—it is impossible not to come to the conclusion that in paying this generous debt of sympathy to the honored dead, the victims of a blow aimed at the King, the country has also declared in language not to be mistaken, that its hope of order, security, and national prosperity, reposes on the dynasty of Louis Philippe.

The *Constitutionnel* contains an extraordinary statement as to the assassin. It is this:—

"The author of the crime is a Corsican of the name of Fieschi, who belonged to the guard of Murat when King of Naples, and who had joined in the expedition in which that Prince fell. On his

return to Corsica he was condemned for stealing a cow to ten years' imprisonment. In 1830 he succeeded, it is not known how, in getting himself inscribed on the list of those condemned under the Restoration for political offences. The Chamber had voted pensions for all these, and Fieschi received his until the end of 1834, when the falsification was discovered, the pension stopped, and he himself obliged to fly. Since 1830, he has been a domestic in the service of M. Caunes, inspector of the waters of Paris. He was recognised by M. Oliver Dufresne, inspector general of prisons; by M. Ladvocat, Colonel of the 12th Legion of the National Guard; and by many others. The discovery was made by M. Dufresne, who had just recovered from the effects of a fall, and made his first visit on Friday to the prison. Fieschi was somewhat annoyed at being recognised, but did not refuse to own that he knew these gentlemen."

We yesterday mentioned that there were doubts as to his identity, and those doubts are now removed in an extraordinary way. The discovery, however, supplies no clue of the motive for the attack. Some insinuations, we see, are thrown out against the Buonaparte family, because Fieschi is a Corsican; but they are probably as gratuitously and wantonly cruel as the immediate arrest, on the commission of the crime, of such respectable gentlemen as M. Armand Carrel and other editors of the liberal Paris papers. We would not indeed allude to the names of any persons in conjunction with that of the assassin had it not been done in other Journals, and had we not wished to express our utter disbelief that any member of the Buonaparte family can have so wickedly conspired to destroy Louis Philippe.

Paris, Aug. 2.—A Joiner, residing in the Rue de Montreuil, has been discovered to be the person who made the framework of the infernal machine, and taken into custody. It was ordered in April last, and executed at that period.

An address, signed by upwards of 900 of the British residents, has been presented to the King by Sir Sidney Smith, expressive of the feelings of his countrymen on the late atrocious attempt.

The autopsy of the Duke of Treviso was effected on the 29th ult., at the Hotel of the Legion of Honor, by Doctors Husson, Poisson, and Julia de Fontenelle. The ball which occasioned his death penetrated obliquely his left ear, and having fractured the mastoid apophysis, and that of the second cervical vertebra, traversed the muscles of the neck. A considerable sanguineous effusion was found in the brain and cerebellum, with clots of blood. A contusion was perceived on the upper part of the head, and on the fore finger of the right hand, which seems to indicate that the Marshal in falling struck those parts.

A subscription has been opened in the Department du Nord for the erection of a monument to the memory of Marshal Mortier, in the Place du Caetau, at Cambrai, and, if possible, opposite the house where he was born.

Of the fourteen victims of the fatal 28th July who have been deposited in the church of St. Paul four only were embalmed before they were laid in their coffins, but on Friday it became necessary for all the others, including the bodies of Colonel Raffé, and Colonel de Roussee, to be subjected to the same process. They were all enclosed in double coffins, one of lead and the other of oak, both sent to the families of the deceased from the King's household; but the fermentation from the decomposition became so powerful that the lead was cracked in several places. A dangerous mephitic gas filled the church, and to avoid the consequences to the visitors it was absolutely necessary to re-open ten coffins, and embalm their respective deposites. This operation, so dangerous from the heat of the weather and the miasma emitted from the putrifying corpses, was performed by several physicians, surgeons and apothecaries of the neighborhood, under the inspection of superior clerks, sent from the office of the minister of the interior, in obedience to a special command from the king, who also sent one of his own aids-de-camp, and in the presence of the director of funerals, the inspector-general of this department in the prefecture of the Seine, a commissary of police, and the mayor of the eighth arrondissement. Such relations of the deceased as were come to pray by the remains of their murdered relatives had the melancholy and painful satisfaction of once more seeing the features of those they mourned.

Our goodly city is obtaining no enviable character abroad. The Liverpool Chronicle, referring to late papers from New York, received by the Carroll of Carrollton, says:

"Beyond, however, the usual and expected quantum of fires and riots, which are far too 'Irish' for us to extract, there is no news."

The House of Lords was occupied on the 7th, from 11 in the morning till 11 at night, in hearing evidence on the Municipal Corporations Bill. It was supposed the evidence would be closed the next day.

In the course of a conversation relative to the proceedings in reference to this measure, the Duke of Wellington said, "There was another consideration which it was important for their Lordships to bear in mind on the present occasion—he alluded to the advanced period of the session of Parliament. It being absolutely necessary that this bill should be taken into consideration, and decided on by their Lordships as speedily as possible, he entreated them not to spend more time in hearing further evidence than was requisite, when they might rather be applying themselves to the consideration of the bill itself."

In the House of Commons, after the presentation of petitions, it was agreed, on the motion of Lord J. Russell, that for the remainder of the session the orders of the day shall have precedence of notices of motions on Tuesdays and Thursdays.

Mr. Hume, addressing Lord J. Russell, said, "he should be glad to know what was the present prospect as to the termination of the session, supposing, as was alleged, that the Municipal Reform Bill should be rejected in another place. In that case, he (Mr. Hume) should feel it his business to submit the propriety of a call of this House to determine what measures should be taken."

Lord J. Russell observed, "that in the event of the bill being thrown out elsewhere, he agreed with the hon. member for Middlesex in thinking that an extraordinary course of proceeding would be required on the part of this House. With that course the motion which he had made could not interfere, as it could easily be set aside in case of urgency or necessity."

On the above the London Times remarks:

Mr. Hume and Lord J. Russell might have known, as well as the Lords themselves know, that there is not, nor ever has been, any intention on the part of their Lordships to reject the measure. We trust, however, that the House of Lords will not refrain from applying to the measure all the amendments that it needs, notwithstanding these very harmless little ebullitions in what Mr. Hume has found out to be the "Great Council of the Nation."

**BRITISH HOUSE OF COMMONS.—The Ladies.**—Mr. G. Berkeley considered his motion for the admittance of Ladies to hear the debates of that House as greatly too important to be deferred. (A laugh.) In former times and until the year 1762, ladies were allowed not only to sit in the gallery of the house, but to occupy seats usually appropriated to Members alone. In the Irish Parliament ladies were always allowed to be present during the debates. In our House of Peers they were also admitted. And why should not they be admitted to the debates of the House of Commons. (Hear.) He was quite aware that an erroneous opinion was prevalent among hon. members that the ladies already possessed too much power and influence in the political world. (A laugh.) But so long as a female could by law wear the crown of England, that was an opinion to the justice of which he would never assent. (Hear, hear.) No one could contradict that females shared as largely in the distribution of intellect as men. (Hear.) It was well known also that the exercise of that intellect had frequently decided elections both for counties and towns. (Hear, hear.) Possessing so much influence over the return of members to that House, it was merely but just that they should be admitted, in order to hear how the hon. members who had been returned by their influence acquitted themselves. (A laugh.) He had been informed by two or three hon. and right hon. gentlemen, that the only reason which made them doubt whether they could conscientiously support his motion, was the apprehension that if ladies were admitted into the House, a number of hon. members, instead of addressing the Speaker, would address

the ladies. (A loud laugh.) Really, he did not think that a sufficient reason for rejecting his motion. A stronger motive for adopting it might be found in the superior one of discussion, which the consciousness of the presence of ladies would necessarily induce. (Hear, hear.) Let the House recollect the violent language and gross personalities in which hon. members now occasionally indulged, and then say if they did not think that the tone of the debates would be much refined and elevated by the presence of the ladies. (Hear, hear.) No hon. member would make a speech of five hours and a half in length if he knew he was drawing so largely on the patience of his female auditors. (A laugh.) There would many other advantages accrue from the adoption of his proposition; and the more he considered the subject the more he became convinced that the admission of ladies during the debates of that House would, in every respect, be highly advantageous. (Hear.) He would conclude, therefore, with moving, in the words of his notice:—

"That a Select Committee be appointed to consider the best means of setting apart and adapting a portion of the strangers' gallery for the admission of ladies during the debates." To which he would add, "that admittance might be granted in such form and manner as the Speaker might appoint"—(A loud laugh)—and, "that provision be made in the new House of Commons for the accommodation of ladies."

A dozen hon. members started up to second the motion, but we believe Mr. French obtained the enviable distinction of doing so.

The question having been put from the chair, the sound of "Ayes" shook the walls of the House.

Lord J. Russell said, that without entering at all into the merits of the question, he would merely observe that he could not acquiesce in the motion, because, in his opinion, if it were deemed advisable to adopt the proposition for the admittance of ladies during the debates, it would be much better that the House should do itself the honor of adopting it, instead of referring it to the consideration of a select committee. Moreover, a select committee appeared to be quite unnecessary, as the honorable member for Gloucestershire had moved that the Speaker should appoint the form and manner in which the ladies should be admitted.

The gallery was then cleared for a division—

For the motion	153
Against the motion	104

Majority for the ladies - 49

The announcement of the numbers was received with vociferous cheers.

On our return to the gallery, Mr. Berkeley was reading the names of the committee; but the confusion of entrance, and the noise occasioned by the shouts of laughter with which some of the names were received, prevented us from distinctly hearing them. The mirth of the House was loudly renewed, when, after the appointment of the committee, the hon. member made the proposition, which was instantly acceded to, that the names of Mr. Pryme and Mr. Pease should be added to the list.

**FROM FRANCE.**—The ship Lorena, Capt. Urquhart, arrived this morning from Havre, having sailed on Sunday the 9th August, bringing Paris dates to the evening of the 7th, being one day later than our previous advices.

The papers continue to give further particulars respecting Fieschi. The *Messenger* of the 1st, says, It is currently reported to-day, that Fieschi alone acted under the influence of the Duchess of Berri, who has been more desirous of avenging her injuries as a woman, than of re-establishing her rights as the mother of the pretender. We are assured that an agent of this Princess, named L. —, remained five days in Paris, but that the police, always skilful, could not find him.

The *Courrier Francais* adds, it is currently reported that Fieschi was employed by the French police as a spy upon the movements of the Duchess de Berri, and was gained over by her or her confidants, and that the attempt of this man was made with the hope of getting a considerable sum of money. It is said that in the depositions of persons intimate with him, they have stated that he had boasted of soon being in possession of 80,000 francs.

[From late Foreign Journals.]

**The Missionary Wolff.**

The annual meeting of the Society for Promoting Christianity among the Jews, was held on Monday evening last, in the Welsh School Room, in Russell street, which was crowded to excess.—With regard to the parent society's proceedings, it was stated that the contributions during the past year have amounted to 12,328*l.* 11*s.* 1*d.* The sum of 540*l.* had been raised at the time of the London meeting, in behalf of the Hebrew church and mission at Jerusalem. A portion of the Church of England liturgy has been translated and published in Hebrew. The Society's school continues to prosper, and there are in them at present 31 boys and 32 girls. Between the London anniversaries in May, 1834, and 1835, 7 boys had been admitted, 3 apprenticed to very eligible situations, and one had died. Out of 72 boys who have left the school during the last 13 years, the committee are only acquainted with eight cases in which they are not conducting themselves in a creditable manner, and even of these none have relapsed into Judaism.

The great attraction of the evening, however, was the Rev. Joseph Wolff, (the Jewish missionary) who addressed the meeting at great length.—The following is an outline of the principal facts detailed by him:—He said he set out on his mission with his beloved wife, who forsook the comforts of home, for the express purpose of rendering assistance to a poor Jew. They arrived at Malta immediately after the battle of Navarino (eight years ago) which was a discouragement to them to proceed. They then went to Cyprus and returned to Cairo. He and his lady travelled through the Deserts of Arabia, seated in baskets slung on each side of a camel, singing as they proceeded, "Guide us, O thou great Jehovah, pilgrims through this barren land," &c. They were surrounded by Robbers, but they got safe to Jerusalem; and here they were destitute of a consul or ambassador, as they had both left the city; but they had a protector, even the Saviour. They passed their time in walking together on Mount Zion, and there beheld the fulfilment of the prophecy, "How does the city sit solitary that was full of people." They took up their abode in a Greek temple, and thither about forty Jews, when they heard of his arrival, came singing, "The Mighty One shall build the city of Zion and give her to thee; then shall he raise from the dust the needy, and from the dunghill the poor," &c.—The Jews, thinking that he disbelieved in their future restoration and conversion, which he did not, read these passages to him, asking what he would make of them. "And many shall go and say come, and let us go up to the mountain of the Lord, to the house of the God of Jacob; and he will teach us of his ways and we will walk in his paths; for out of Zion shall go forth the law, and the word of the Lord from Jerusalem, and he shall judge among the nations, and rebuke many people; and they shall beat their swords into ploughshares, and their spears into pruning-hooks; nation shall not lift up sword against nation, neither shall they learn war any more." Such passages make a great impression in that literal Zion. "For Zion's sake I will not rest, until the righteousness thereof go forth as brightness, and the salvation thereof as a lamp that burneth." Mr. Wolff observed, that the Jews said to him, "Look here, this is Jerusalem, say ye, to the daughters of Zion, behold thy salvation cometh." He would tell them the answer he gave the benighted children of the promise, "Cast ye up, cast ye up, prepare the way: take up the stumbling block out of the way of my people," a passage which is particularly forcible there, for in going towards Jerusalem the way is exceedingly stony; and when the Pasha travels towards the city, the Arabs, while they gather up the stones, cry out, "Cast ye up, cast ye up, prepare the way, gather up the stones out of the way." He agreed with them in the truth of all these passages but treated them to reflect upon others which especially concerned their salvation—such as "He was despised and rejected of men; a man of sorrow and acquainted with grief." "They shall look upon him whom they have pierced, and mourn." Having travelled upwards of twenty thousand miles, he found it difficult to be brief, but he must pass on to Cairo, and thence to Alexandria, where he left his wife. From this place he set out for Tenedos, where he distributed the scriptures to the Greeks: for though he was a Jew, he loved, like his Saviour, the be-

nighted Gentiles, believing with the Apostle, that "there is neither Jew nor Greek; there is neither bond nor free; there is neither male nor female—for we are all one in Jesus Christ." From Tenedos he went to Lemnos, and then to Mount Athens, where he distributed the scriptures; from thence to Salonica, where he was recompensed for his sufferings by having the pleasure of preaching to upwards of one hundred Jews, and distributing the New Testament among them. He said travellers had often told him that they had seen the books which he circulated torn in pieces. This might be the case in reference to some of them; but he had no doubt that the contents of the Bibles and Testaments he circulated found their way both to the heads and hearts of numbers. Mr. Wolff said he, determined to go from Salonica to Bokhara, Oeskoro, Ancient Phrygia, &c., to carry the gospel where it never shone. In his journey, he observed the Apostles' plan, preaching Christ even in the synagogues, and in proceeding to Meschid, Balk, and other places, he was told he should certainly be put to death. He thought he would use great prudence at Chorazan, but human prudence often fails, and therefore he went to the nearest governor to request him to protect him (Mr. Wolff) on his journey to Bokhara, there being continued wars with the Turcomans, a savage race of people, who, he heard, always sold their prisoners for slaves.—He told him he was always ready to serve an Englishman; but when he knew what the speaker wanted, he desired him to write an order upon the king of England to grant him a pension of 10,000*l.* per annum. Mr. Wolff told the chief he could write the order and put his seal to it, but he greatly feared that his order would not be honored. Then, said the chief, you may go where you please. Mr. Wolff said he then set off for Herat, and had travelled about thirty miles, when two horsemen came after him, and brought him back, declaring that he had stolen ten thousand pieces of money; and it was in vain that he told them that he had not a hundred pieces. On arriving before the chief again, his Bible attracted the attention of the people, and he read some passages to them, translating them as he proceeded, and distributed twenty copies in the Persian language, which he afterwards saw this barbarous people reading in the streets. He was from this place escorted to Terschiz, where he saw the streets filled with the dead bodies of men, killed by the Turcomans, who had been there and taken away 1500 prisoners, burning the villages as they proceeded along. At this time, said Mr. Wolff, I understood better than I had ever done before an expression in the Psalms. The Arabs were mourning and exclaiming, "Our bones are broken! our bones are broken!" signifying that they were greatly afflicted. Then came forcibly to my mind the passage of Scripture, "Make me to hear joy and gladness, that the bones which thou hast broken may rejoice." He afterwards proceeded to say that the Khan of Terschiz refused to furnish him an escort, and he went on with his servant being joined by seven muleteers. On the road they heard firing, and shortly afterwards twenty-four horsemen came up and surrounded the muleteers—they did not see him (Mr. Wolff) for half an hour afterwards; however, at last, one of the party came up to him, and demanded some money: he gave the man some, and told him he had more. He requested him not to tell his comrades that he had got any from him; he had scarcely spoken, when the remainder of these ruffians came up and took all the money Mr. Wolff had from him; and on discovering that their comrade had concealed what he had got from him, they gave him a good flogging. The party then tied him, (Mr. Wolff,) after stripping him, to the tail of a horse, and as they went along kept flogging him continually. It is in such an hour as this, said the reverend gentleman, that we learn to pray in sincerity; I prayed to my Saviour to help me, and he heard my supplication and delivered me.—For those who were ill-treating me, after listening to my prayers for some time, unbound me, and put me upon the horse. When they halted, they valued all the captives they had taken: Mr. Wolff's servant, they said, was worth 10*l.*; but when they came to the individual who was now addressing the meeting, they desired him to open his mouth; one of them looked into it, and exclaimed, "O, he is not worth much, he has lost three teeth already." They said he was good for nothing, but might fetch three pounds. On searching my papers, my captors found the firmans I had got from Abbas Mirza, Prince of Persia, and they were

afraid, and said one to another; "This is no common man; let us kill him, or we shall lose all the rest." I entreated them not to kill me, and I would put them in a way to get their price for me. I then wrote in some of the New Testaments, 'To the Jews at Terbad Hydarca, in Khorassan; I, Joseph Wolff, of the Jewish nation, who goeth about to proclaim Jesus Christ, have been made a slave, purchase me and I will give you the money back.' These books were immediately sent off, but they still consulted about killing me. I said to the chief, Abel Hassan, "I see what you are about—I am sure you will all be killed if you kill me." Mr. Wolff said, he believed that the remark he made to the chief kept these lawless brigands from murdering him; yet, though they did not do this, the day before they arrived at Terbad Hydarca, seeing he was not a good horseman, they put him upon a wild horse, whipped the animal behind, drove him up the mountains, hoping that he would tumble off his back and thus be destroyed; but, said Mr. Wolff, in this expectation they were disappointed, for I sat as fast and as steady on my steed as a colonel of cavalry. At last they got to the city, a most awful place; on their entering it, the Moguls and Turcomans came out and offered praise to God that they had made so many slaves. He (Mr. W.) saw some Jews coming out to look at the captives, and he exclaimed, "Hear, O Israel, the Lord our God is one Lord." A Jew immediately came up to him, and taking his bible and journal, he hid them under his clothes, at the same time telling the barbarians he would settle every thing about me. Soon afterwards, the same Jew took him to his house, and as he was naked, and almost frozen, he gave him some brandy; and he (Mr. Wolff) was certain, that in the circumstances in which he then was, the most zealous members of the Temperance Society would not have refused to drink it. The Jews questioned him about the books he had got; and all night he was engaged in reading and explaining the New Testament to them. The Jews there were not so hardened against the Saviour; for they say, that as their fathers left Jerusalem, after the Babylonish captivity, and they never returned, they had no share in the crucifixion of Christ. In the morning they invited him to accompany them to their Synagogue, where he again read and explained the New Testament; and though so greatly fatigued yet his heart rejoiced with unspeakable joy, that he was again permitted to speak to his own nation about Jesus Christ and him crucified. The next day (said Mr. Wolff) I was brought back and put in chains with the other prisoners, Mahomedans, who cursed me, and continually cried out, "this infidel makes me unclean." In about half an hour after I had been locked up in an awful dungeon, the door was opened, and some one asked, if any English were there. I instantly answered the call, and was taken out of the dungeon. Here was an answer to prayer; Abbas Mirza had heard of my being captured, and had sent horsemen to demand my release; an English officer in his army lent me money and clothes; and he afterwards ordered them to escort me to Bokhara; from thence I proceeded to Calcutta under the protection of the Persians. On my arrival there, I was hospitably treated by Lord William Bentinck, Dr. Morrison, and other Christian friends; and here I am among you, willing to go wherever the Lord directs me, to preach salvation to the House of Israel. Though I may be called an enthusiast, a hypocrite, or an impostor, or any thing else, I am resolved to live and die in the cause of Christ. (The Rev. gentleman sat down amidst the most deafening applause.)

**AN HONORABLE PLEDGE.**—During the consular sway of Napoleon in France, and when the conscriptions were in full force, there lived in one of the provinces of the south a very aged man, who exercised the profession of a tailor, and had twelve sons, all of whom served in the armies of Napoleon. They having one day obtained leave of absence from their regiments, made use of the opportunity to go and visit their aged parent, but on their arrival were shocked to find that he was so reduced in circumstances as to be in want of bread. "No bread!" cried one of them—"the man who has given twelve conscripts to his country! We must procure him sustenance—yet how? We are ourselves destitute."—"Is there no pawnbroker in the neighborhood?" exclaimed the youngest, who placed great confidence in the compassion of human beings, as well as reliance on his Creator. "A pawnbroker! What good would that do? we

have indeed nothing to pledge!" "You shall see brother. Our father is known to be an honest citizen, who has exercised his trade long enough, and being destitute of bread, that is a sufficient proof of his integrity. We also have all served during several years, and no one can cast the slightest imputation on our honor. Let us pawn this 'honor'—certainly there will be some who will willingly lend us fifty louis on such a pledge!" This idea was immediately approved of, and the twelve brothers wrote out and signed on the spot the following billet: "Twelve Frenchmen (sons of a tailor, who at the age of near 90 years, is fallen into the deepest poverty,) all zealous in the service of their country, request from the directors of the pawnbroking establishment the loan of fifty louis-d'ors, to assist an unfortunate father. As a security for the payment, we pledge our 'honor,' and promise to repay the said sum within the space of one year." The billet was brought to the money office, where the benevolent directors immediately counted out the fifty louis asked for, and tore the obligation in pieces, pledging themselves, at the same time, to provide for the old man as long as he lived.

**THE AMUSING SCENE IN A BARBER'S SHOP,** which we copy to-day from *Mephistophilis in England*, is, as our readers will readily recognize, a burlesque upon Cobbett, under the name of *Billy Gridiron*. The keeping of the whole scene is so admirable, that it might readily pass for an actual occurrence.

[From *Mephistophilis in England*.]  
**Scene in a Barber's Shop.**

In the centre of the apartment a tall and cadaverous looking individual, with high cheek bones, red whiskers, and crop to match, most luxuriantly curled, wearing an apron which was once white (bearing in his huge pockets his professional apparatus,) and with sleeves of a similar fabric, was operating upon the chin of a customer, an apoplectic looking man, with a red nose and a capacious corporation, landlord of the neighboring public-house, whose beard he had nearly succeeded in removing. Shortly after I had entered, a person made his appearance, dressed like a respectable farmer, his face of a florid complexion, with features expressive of health and good humor, and his hair of a pure silvery whiteness. He was strongly built, evidently in the possession of all his faculties, and he might be about sixty years of age. He strode into the room, seemingly taking no notice of any person present; sat himself down in an empty chair, and took up the preceding day's edition of the Times. Glancing his eye hurriedly over the leading articles he every now and then exclaimed,—"Pooh!" "Fudge!" "Twaddle!" "Cant!" "Lies!" Then observing the barber at leisure, he flung down the newspaper in disdain, and placed himself in the vacant seat.

"Mister Kennedy received his customer with a bend which was meant to be graceful; and, after having fixed a cloth under his chin, proceeded to make the lather of the proper consistence.

"A braw day this, sir!" blandly insinuated the man of shaving.

"Yes!" briefly replied the unknown.

"The operator then commenced sharpening his razor on a leather strap, nailed to the table; but during the process his tongue was not allowed to remain in idleness. By a wise dispensation of Providence, barbers have been gifted with extraordinary conversational activity. The great ant-eater inserts his long tongue into the ant's nest, and the poor insects, attracted by its smoothness and oiliness, throng round it, and are devoured. The barber catches his prey by the same means.

"Sure, sir, ye've been reading the noos?" inquired the barber, as he stropped the razor; 'tho' I'm anything but indifferent to the public weal, I canna find time to mak mysel acquainted with a' the transactions o' state. These poltical changes in my hoomble opinion, are of nuckle importance. Dinna ye think so, sir?"

"I don't know!" gruffly replied the interrogated individual.

"You see, sir," continued the talker, nothing daunted, 'the present parliament have labored weel, for the public gude. It canna be denied, they might have conferred upon the kintra many substantial benefits which they have neglected doing. But Rome was na built in a day, was it, sir?"

"I didn't build it," answered his victim, more gruffly than before.

"For my part," continued the barber, laying the lather rapidly over the beard of the person he was speaking to, "I am quite dissatisfied with that Reform Bill they made sic a fuss about. What has it done? nothing. Where are a' the advantages the minsters promised it should confer upon the people? I have not met with a single individ- ual who has gained the smallest profit by the pass- ing o' that measure. But you see the hale kintra was mad about it, sir. Folks ran gabbling from house to house, as if they were demented; and if you listened to the 'puir daft creturs, you would have imagined that, when the Reform Bill became the law o' the land, legs o' mutton and quarten loaves would go flying in at every poor man's windy. It was morally impossible, in the nature of any leegislative measure, to come to sic a catastrophe: and so I told 'em. I reasoned wi' em logically and pheelosophically on the subject. But they would na' listen to reason; and they ha' now the pleasure of reaping the fruits o' their disappoint- ment." After a pause of a few seconds' duration, in which the operator got his razor in readiness, he continued, "Did you see any thing interesting in the Times, sir?"

"I never see any thing but lies in that beastly paper," observed the stranger, with some asperity. "Hoot awa, mon!" exclaimed Mr. Kennedy, with considerable surprise; "sure as it's the lead- ing journal; a maist respectable periodical! profes- sing leebler opinions; always pooblishing the ear- nest intelligence; and then its leading articles are so pointed and clever! The lads must ha' sharp wits that write 'em." He commenced his attack upon the bristles, yet continued his conver- sation, with the nose of his victim between his fin- ger and thumb, while the edge of the razor was gliding over the chin.

"There's an uncommon clever article in yester- day's paper, which deserves your attention. It's an attack—sic a smart attack isn't written every day in the year—on that archimpostor, Billy Grid- iron. Sit still, Sir, or maybe ye'll get a cut wi' the razor!—Ye see, the old bone-grubber, in a number o' his Poetetical Register, a blackguard pooblication, which no respectable mon will alloo in his house.—I beg, Sir, ye'll sit still! It's unco dangerous to wriggle ye're chops about in sic a fan- tastical manner! The old atheistical seepoblican attacked the Times! only think o' the fellow's as- surance, to go to abuse the leading journal! And he called it the bloody old Times, and mony sic sanguinary epithets. But he's a shocking low fellow, sir; and like his old crony, Tom Paine, whose bones he brought over fra' America, doesn't care a fig for morality or religion. Well, I never met with any person so feedjitty as you are: sure ye must be uncommon nervous!—Well, sir, the editor of the Times gangs at him, and in the twink- ling of a bed post, smashes him to a mummy. Oh, the puir deevil has had sic a handling, that I doot vary much if he ever recovers it. But I'm glad on't. It serves him quite right. The vagabond ought to have been hanged long ago; don't ye think so sir?"

"The only reply the barber got to his question was a rude shove, given with all the stranger's strength, that sent the former and his razor spin- ning in different directions. At the same moment up jumped the stranger, with the lather remaining on one side of his face, the cloth about his shoul- ders, his eyes flashing fury, and his appearance bearing that of a man who had vainly endeavored to suppress his passions, but had now determined to allow them their full indulgence. As the barber fell to the ground, the black cat awoke from her sleep, and raised her back in alarm; and the pa- rish apprentice dropped the curling irons from his trembling grasp, and opened his mouth with amaze- ment.

"You nasty, lousy, stinking Scotchman!" ex- claimed the stranger to the prostrate shaver.

"It's false, sir, I'm nothing o' the kind!" replied the other, rubbing that muscle known to the anat- omist as the *gluteus maximus*; "and if there's sic a thing as law to be had, I'll have it. A pretty thing, indeed, if industrious tradesmen are to be assauld- ed and abused in this shameful fashion. Sir, ye've insulted me! Ye've cast reflections on my coun- try!"

"Your country!" said the stranger, contemptu- ously; "why, you don't mean to style that miser- able, dirty, beggarly province, called Scotland, a country? the home of rags and filth, of disease and vermin; a wilderness of barren rocks and fe- ted lakes; where nothing grows but the heather

and the thistle, a few stunted fir-trees, and some half-withered pines. A wretched place, inhab- ited by a few beggarly, thievish, cowardly mit- creants—"

"Cowardly!" exclaimed the indignant Scotch- man, as soon as he could find courage to interrupt the torrent of abuse directed towards his beloved birth-place: "do ye call the people of Scotland cowardly? Were Wallace, were Robert Bruce, were the victors o' Bannockburn cowards, ye false loon?"

"Yes, you poor, pitiful sneaking knave, they were all contemptible cowards, or they would have stood up and fought the Englishmen, instead of stealing about like thieves in the dark, and surpris- ing their enemies when off their guard. The bat- tle of Bannockburn is their grand boast; and how did they gain that? By digging pits, into which a tired army and imbecile king were entrapped; a stratagem worthy of their Tom Thumb—the great heroes! Did they ever gain a fair stand-up fight? Halidan Hill, Falkirk, Cuten Moor, Flooden Field, and Neville Cross, reply in the negative. A treacherous, malignant, vindictive race. Who be- trayed Charles the First?—the beggarly Scotch- men; and they would have betrayed their fathers for the same sum. Who destroyed poor Mary Stuart?—the beggarly Scotchmen; and they would murder their mothers if they thought they could gain anything by it. And yet the despise- ble scoundrels mention England as owing all her glory to them! When did they ever produce a Nelson, a Marlborough, or a Wellington? They boast, too, of monopolizing all the wisdom and genius of the kingdom. Where are their Shaks- peares, their Miltons, their Newton's, their Bacon's? The only poet they ever had, was Burns, and him they starved to death; the scabby, shab- by, stingy vermin. And what sort of literawice do they now possess? A parcel of ignorant, impudent, unprincipled fellows; who pretend to write about feelings, and poetry, and the Lord knows what, without being able to compose a sentence of decent grammar; and inundate this country with their trash. The boastful Scotchmen; they have the impudence of the devil? Why, it was but the other day that a vulgar wretch of a journeyman stonemason took it into his head to scribble what he called the Literary History of the last Fifty Years! It would have made a horse laugh to read the superficial twaddling rubbish the poor wretch published. England owes Scotland for a race of kings the most tyrannical, profligate, and mean that ever disgraced the English throne. She is also in- debted to that humane people for the invention of a new species of murder, for the sale of the dead body, called Burking. A set of crouching, cant- ing, unprincipled hypocrites, who come over to this country like a swarm of locusts, devouring the very substance of the land, and go spreading their pestilential persons over the whole world; cring- ing, fawning, flattering, lying their way into wealth and power. Hear a Scotchman speak of his coun- try, you would think he could not exist out of it; and yet, of the thousands who leave it for the more fertile shores of England, scarcely one ever thinks of returning. A swaggering, bragging, drunken crew, who talk of their morality, forsooth! Why, 'tis enough to make an honest stomach heave to hear the lies they tell in their own praise. They boast of their temperate habits, and are known as inveterate dram-drinkers, swilling their filthy thimble with their smokey whiskey; and will pig on any sort of filth set before them; their haggis and brose would sicken an Englishman. They boast, too, of their feelings, and have invented a science called Political Economy—a set of mis- erable twaddlers, who publish the most mischiev- ous, wicked, and nonsensical opinions on a subject of which they know nothing.

"I said long ago that political economy was a parcel of rubbish, collected by a few revolutionary adventurers for their own profit. I said so, and, like all I say, the truth of my opinion has since been proved. Parson Malthus has ceased to gain as many fools as he used to do. I said the humbug would be found out; and I predicted what would be the consequence if Peel's bill became the law of the land. I predicted that the Catholic Emancipa- tion Bill, when passed, would only add to the dis- turbances and wretchedness of that devoted coun- try, Ireland. I predicted that bank notes would soon be considered old rags, and that every one would strive to possess gold. I predicted a hun- dred other things of equal importance, and all my predictions were fulfilled to the letter. Have I not

saved the country over and over again, when it was on the brink of perdition? and had the govern- ment taken my advice, England would now be a fine, flourishing, powerful kingdom, instead of being devoured by its huge debt, its greedy placement, and horrible taxation. But the people know what I have done for them; they see that I am the only man capable of setting things to rights; and the king, and all his ministers, will be obliged at last to come cap in hand to me, to pray that I would help them out of the cursed hobble into which their own misgovernment has placed themselves and the nation!"

"Then, in the name o' the deil, who are ye?" asked the affrighted barber, gasping for breath; while the parish apprentice stood with his mouth open, endangering every fly in its immediate neigh- hood; and the black cat raised her back higher than ever, and stared her yellow eyes out of her head.

"Who am I? you snivelling, snarling, sneak- ing Scotchman," repeated the stranger, as with the napkin fixed round his neck he wiped the soap from his chin, "I'm BILLY GRIDIRON!" Then throwing the cloth at the terrified barber, who, at the mention of his name, had again sunk on the floor, he darted out of the shop."

#### SUMMARY.

NAVAL.—An order for building a new steam Frigate, was, we understand, received at the Navy Yard on Saturday last. The model was received, and the timber got out, yesterday. Her force, it is said, will be twelve guns.

The President of the United States has officially recognized F. L. Brauns, Esq. as Consul of Saxony for the port of Baltimore.

The Dutch frigate De Mars, Capt. Arriem, and the brig-of-war Smeeneid, Capt. Ferguson, which arrived here from Curacao on the 24th ult., sailed early yesterday morning for Flushing. Soon after getting under way, they complimented the city with the usual salute. On Tuesday his Honor the Mayor gave a splendid dinner to the young Prince and the officers of both vessels. In the evening they attended the Park Theatre, accompanied by Major General Morton.—[Gazette.]

A dinner was given at the Mansion House, on Thursday, by the St. Nicholas Society, to Prince Hendrik, of the Netherlands, who recently arriv- ed in this country in a Dutch National vessel, Chevalier Martini, Chargé of the Netherlands to the United States, and Col. Arriens, of the Dutch frigate De Maas, now lying in the harbor of New York. Several other officers and gentlemen con- nected with the two vessels of war were expected to have been present, but owing to the necessity of sailing in a few days, some of them were obliged to leave the city on Wednesday.

Among the guests present, were the governor, and the Mayor and Recorder. The venerable Pres- ident of the Society, Alun. Van Vechten, presid- ed, assisted by Harmanus Bleeker, Esq. and Gen. Solomon Van Rensselaer. The proceedings were characterized by the warmth and feeling that might have been expected on such an occasion; and we doubt not that this expression of regard from residents of our ancient city, the descendants of "Va- dor Landt," was reciprocated by the Prince and his companions.—[Alb. Argus.]

#### Extract of a letter from Buffalo.

The U. States Bank has sold out its debt here of \$650,000. Judge Rochester, D. E. Evans, Day & Burt, S. Thompson and Charles Townsend, are the purchasers. They get one, two, three and four years to pay in, at 5 1-2 per cent. interest, and charge 7. It is done ostensibly to relieve the deb- tors of the Bank, and probably will, many of them. —[Jour. of Com.]

GALENA, 29th August.—The Land Office at this place was opened on the 8th of June last, and from that period to the present time, there has been received for lands sold, Two Hundred and fifty thousand dollars. The district of country, where purchases have been made is below this, bordering upon, or in the vicinity of Illinois River, lying mostly, within the counties of La Salle and Put- nam; a body of land, generally speaking, equal to any in the State; and that is as much as to say, inferior to none in the Union.

We are happy to learn that five thousand two hundred dollars have been collected in this city, for the relief of the aged officers and soldiers of the revolutionary war.—[Gazette.]

**LUCIFER MATCHES.**—A friend of ours who was bound up the North River a few days ago, happened to be early on board the Ohio, and so sat himself down on the back side of the boat to read a book. As the bustle increased, and just as the boat was starting, a porter threw down a trunk at his feet, took two shillings of a countryman for his trouble, and hurried off. Directly our friend discovered an impression of fire on his olfactory nerve, and looking about, beheld the countryman's trunk smoking like a coal-pit. On being opened, it exhibited a doleful mass. In addition to a quantity of Lucifer matches, the countryman had furnished himself with a quantity of small torpedoes which had also exploded, so that the silks and calicoes for the ladies, and the sugar plums for the children, were all in ruins. The affair was hardly over, when our friend walked to another part of the boat, where several gentlemen of his acquaintance were regaling themselves with segars, and beheld the pocket of one of them was smoking almost as much as the countryman's trunk! "Mr. —," said he, "your pocket is on fire,"—and the gentleman pulled out his linen cambric handkerchief, which on coming to the air, blazed up beautifully. The friction of throwing a bunch of matches back into his pocket after taking one to light a segar, had been sufficient to produce an explosion. The countryman's matches were exploded by the concussion of throwing down the trunk. In Germany severe laws have been passed against the having, making, or using Lucifer matches.—[Jour. of Com.]

The following tributary lines are ascribed to the Rev. Andrew Reed, of England, who was recently in the United States and visited the tomb at Mount Vernon:

Washington,  
The brave, the wise, the good:  
Washington,  
Supreme in war, in council and in peace:  
Washington,  
Valiant without ambition, discreet without fear;  
And confident without presumption:  
Washington,  
In disaster calm; in success moderate; in all himself;  
Washington,  
The hero, the patriot, the christian;  
The father of nations, the friend of mankind;  
Who,  
When he had won all, renounced all,  
And sought,  
In the bosom of his family and of nature,  
Retirement;  
And in the hope of religion,  
Immortality.

[From the National Intelligencer.]

#### The American Sword.

FORGED from Oppression's chain;  
Valiantly used,  
Wielded when prayers were vain;  
Never abused:  
Sword, that our fathers drew!  
We, by their dust,  
Swear to prove good and true  
Heirs of the Trust.  
Should e'er domestic strife  
Call for thy steel,  
Be thou the pruning knife,  
Wounding to heal!  
Should Freedom's foes accurst  
E'er seek our shore,  
Forth like God's lightning burst  
Even as of yore!  
Blood rusts thy blade upon:  
Why was it shed?  
Answer from Lexington,  
Glorious Dead!  
Cry, from your lowly rest  
Neath the green sod,  
"Sons! for our rights, the blest  
Charter of God!"  
From our Sires' hallowed earth  
Breathes a deep tone:  
"Not for the South or North  
Fought we alone:  
All in one holy band  
Sought we to bind—  
Oh! let not factious hand  
Loose what we have joined!"

#### STEPHENSON,

Builder of a superior style of Passenger Cars for Railroad,  
No. 264 Elizabeth street, near Blecker street,  
New-York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. J341f

#### AUBURN AND SYRACUSE RAILROAD.

##### NOTICE TO CONTRACTORS.

Sealed Proposals will be received until the 15th day of October next, at noon, by the undersigned, Chief Engineer and Agent of the Auburn and Syracuse Railroad Company, for the Grading, Masonry, and Bridges on said Road.

Individuals disposed to contract for the execution of the whole or any part of the work, will be furnished on application at the Office of the Company in Auburn, with blank forms of proposals, and printed specifications.

The contracts will be formed in the usual manner—a specific price being stated for each item of work, which price is to include the cost of material and labor required in rendering the work complete.

The proposals to be accompanied with the names of sureties, and where the parties are unknown to the undersigned or resident Engineers, the usual certificates of character and solvency will be required.

Individuals who have been employed on other works, must furnish satisfactory recommendations from the Engineer or Superintendents of the same. A rigid adherence to the conditions of each contract will in all cases be required.

It is desired that all the work in each section, including Grading, Culverts, and Bridges, should be embraced in the same contract, and it is requested that the proposals be made accordingly.

The plans of the different structures will be ready for examination at the Office aforesaid, by the 1st day of October next.

EDWIN F. JOHNSON,  
Chief Engineer & Agent A. & S. R. Company.  
Auburn, Aug. 22, 1835. 37—150

#### NEW-ORLEANS AND NASHVILLE RAILROAD.

##### NOTICE TO CONTRACTORS.

The New-Orleans and Nashville Railroad Company having decided to place under contract the first fifty miles of the Road, on the 15th day of December next, Proposals will be received at their Office, in the City of New-Orleans, from the 15th of November to the 15th day of December next, for the Graduation and Bridging of the same.

The Superintending Engineer, R. S. Smith, will be upon the ground to give every explanation relative to the manner of making Proposals, and such other information as may be required.

Of persons not personally known to the Engineer, there will be required certificates of character and qualifications.

This part of the road, extending along the shore of Lake Pontchartrain, is perfectly healthy throughout, and being the commencement of the most extensive work in the world, it cannot fail to be of great importance to Contractors to identify themselves with the work at its commencement, as those who are known to the Company as responsible and efficient will certainly be preferred to strangers during the future progress of the road.

The country through which the line passes is generally high pine ridge, and perfectly healthy.

H. J. RANNEY,  
Chief Engineer N. O. & N. Railroad.  
Engineer Office, N. O. & N. Railroad,  
Aug. 25, 1835. 37

#### TO CONTRACTORS FOR EXCAVATION AND MASONRY.

PROPOSALS will be received at the Office of the Philadelphia and Reading Railroad Company, in Philadelphia, on the 19th and 20th days of October next, for the Grading and Masonry, of about sixteen miles of the Railroad between Pottsgrove and Norristown.

In this distance, a large amount of heavy work, deserving the attention of skillful and competent Contractors, is to let. The Jobs of most magnitude, are a Tunnel 600 yards long, and a Bridge across the Schuylkill, near Phoenixville.

Plans and profiles of the line, and drawings of the different constructions on it will be exhibited, and all other information in relation to it will be afforded, on application at the Engineer's Office, at Pottsgrove, for ten days previous to the letting.

MONROE ROBINSON, C. E.  
Philadelphia, Sept. 2, 1835. s2 StawtO19

#### AMES' CELEBRATED SHOVELS, SPADES, &c.

500 dozens Ames' back-strap and plain Shovels,  
75 do do round-pointed do  
150 do do cast steel Shovels and Spades,  
100 do do Socket Shovels and Spades,  
150 do do steel plated Spades,  
Together with Pick Axes, Churn Drills, and Crow Bars, steel pointed, made from Salisbury refined iron. For sale by his Agents,

WITHERELL, AMES & CO.  
2 Liberty street, New-York.  
BACKUS, AMES & CO.  
8 State street, Albany.  
34—ytf

#### RAILROAD IRON WORK,

Of all kinds, made to order by GODWIN, CLARK & CO., Paterson, New-Jersey.

CAR WHEELS, BOXES, AXLES, and CAR SPRINGS, made complete at short notice, and fair prices. Orders addressed to them at Paterson, N. J., or 24 Broad street, N. Y., will meet with immediate attention.

Paterson, Aug. 19, 1835. 34—ly

#### RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order car wheels, chairs and knees, and every other description of castings required for railroads. R-ly febl4

#### RAILROAD CAR WHEELS AND BOXES AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS.  
Also, Flange Tires turned complete.  
J8 ROGERS, KETCHUM & GROSVENOR.

#### TO TUNNEL MINERS, DRILLERS, &c.

Wanted, immediately, 40 Tunnel Miners, (Cornish Miners will be preferred,) 80 Drillers, 50 Laborers, and two experienced Mine Blacksmiths, on the New York and Harlem Railroad, about five miles from the City. Liberal wages will be given, and cash payments made every fortnight. Apply at Mr. FOWLER'S, St. John's Hall, Frankfort street, New-York.

JOHN RUTTER, Contractor.

37 The Albany Argus, Philadelphia U. S. Gazette and Pennsylvania, will please copy this, and send their bills to the Railroad Company, 14 Wall street, New-York. 23—4f

#### PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

Railroad Spikes of every description required, made at the Albany Spike Factory.

Spikes made at the above Factory are recommended to the public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to admit water.

Orders may be addressed to Messrs. ERASTUS CORNING & CO., Albany, or to THOMAS TURNER, at the Factory, Troy, N. Y. sept.18-ly

#### RAILWAY IRON.

35 tons of 1 inch by 1/2 inch, Flat Bars in lengths of 200 do. 1 1/2 do. do. 14 to 16 feet, counter sunk 40 do. 1 1/2 do. do. do. holes, end cut at an angle 800 do. 2 do. do. do. of 45 degrees, with splitting plates and nails to suit 800 do. 2 1/2 do. do. do. soon expected.

250 do. of Edge Rails of 36 lbs. per yard, with the requisite chairs, keys and pins.

Wrought Iron Rims of 30, 33, and 36 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels.

Axles of 24, 28, 32, 34, 36, and 38 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment.

A. & G. RALSTON,  
9 South Front street, Philadelphia.  
Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them. d7lmcowr

#### SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by

E. & G. W. BLUNT, 154 Water street, corner of Maiden lane.

#### SURVEYING AND ENGINEERING INSTRUMENTS.

The subscriber manufactures all kinds of Instruments in his profession, warranted equal, if not superior, in principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Goniometer, with two Telescopes—and a Leveling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes.

WM. J. YOUNG,  
Mathematical Instrument Maker,  
No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested.

Baltimore, 1833.  
In reply to thy inquiries respecting the Instruments manufactured by thee, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish thee the following information. The whole number of Levels now in possession of the department of construction of thy make is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accidents to which all Instruments of the kind are liable.

I have found that thy patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a reversing telescope, in place of the vane sights, leaves the engineer scarcely any thing to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,  
JAMES P. STABLER, Sup't of Construction of Baltimore and Ohio Railroad.

Philadelphia, February, 1833.

Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.  
Germantown, February, 1833.

For a year past I have used Instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these Instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

HENRY R. CAMPBELL, Eng. Philad.  
Germantown and Norristown Railroad

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, SEPTEMBER 26, 1835.

**RUNNING GEARS OF RAILROADS.**—We commence in this number, "A Dissertation upon the Running Gears of Railroad Carriages," by Mr. JAMES STIMPSON, of Baltimore, which will be found well worth reading. It will be concluded in our next.

**SANDY AND BEAVER CANAL.**—We would call the attention of those contractors who are accustomed to tunneling for Canals or Railroads, to an advertisement of E. H. GILL, Esq., Engineer, in this number of the Journal—from which it will be seen, that the Tunnel is to be about 900 yards, or nearly half a mile, in length—mostly through a sand-stone rock.

### TO TUNNEL CONTRACTORS.

Proposals will be received by mail, or otherwise, for excavating a Tunnel on the summit of the Sandy and Beaver Canal. The Tunnel is 900 yards long, the material to be removed is a soft sand-stone rock, the highest part of the ridge through which it passes is about 90 feet above the top of the Tunnel. As the deep cuts at the termination are not excavated, most of the material will have to be removed through shafts. Proposals must be accompanied with good recommendations, as to skill and competency.

E. H. GILL,  
Engineer.  
38-41

New-Luton, Ohio, Sept. 17, 1835.

**NEW-ORLEANS AND NASHVILLE RAILROAD.**—This road, which at first, by many

of our readers, and indeed even by ourself, was considered more as a subject of conversation, than of serious consideration, is to be pushed forward with energy and spirit. Fifty miles of the road, as will be seen by the annexed notice, is to be put under contract in December next. And it affords us pleasure to say, as we are enabled to do, from information derived from the President and Chief Engineer,—the latter of whom, H. J. RANNEY, Esq., is now on his way to Liverpool, to make contracts for the Rails,—that the Company intends to make it a road of the most substantial character, especially where a wood rail and a flat bar of iron are used. The superstructure is to be of wood. The wood rail is to be 7 by 9 inches, and the iron rail 2½ by 1½ inches, which is, we believe, both thicker and wider than any other flat rail in use.

The survey proves this route to be one of the most feasible that has been projected in any part of the country. The maximum ascent, in the direction of the greatest business, that is towards New-Orleans, is only ten feet per mile, and from New-Orleans it is only 20 feet.

We expect to receive a copy of the report of Mr. Ranney in a few days, when we shall enter more into particulars. In the mean time we would call the attention of contractors to the following notice.

### NEW-ORLEANS & NASHVILLE RAILROAD.

#### NOTICE TO CONTRACTORS.

The New-Orleans and Nashville Railroad Company having decided to place under contract the first fifty miles of the Road, on the 15th day of December next, Proposals will be received at their Office, in the City of New-Orleans, from the 15th of November to the 15th day of December next, for the Graduation and Bridging of the same.

The Superintending Engineer, R. H. Smith, will be upon the ground to give every explanation relative to the manner of making Proposals, and such other information as may be required.

Of persons not personally known to the Engineer, there will be required certificates of character and qualifications.

This part of the road, extending along the shore of Lake Pontchartrain, is perfectly healthy throughout, and being

the commencement of the most extensive work in the world, it cannot fail to be of great importance to Contractors to identify themselves with the work at its commencement, as those who are known to the Company as responsible and efficient will certainly be preferred to strangers during the future progress of the road.

The country through which the line passes is generally high pine ridge, and perfectly healthy.

H. J. RANNEY,  
Chief Engineer N. O. & N. Railroad.  
Engineer Office, N. O. & N. Railroad,  
Aug. 25, 1835. 37

**GEORGIA RAILROAD.**—We are gratified, says the Augusta, Geo., Constitutionalist of the 8th inst., in being able to inform our readers, and the friends of this laudable undertaking throughout the State, that the work on this road is steadily progressing under the direction of its chief engineer, J. EDGAR THOMSON. The line of this road, after leaving Augusta, pursues the elevated piney ridge, separating the waters of the Savannah river from those of Brier Creek and the Ogeechee. This ridge is celebrated for its salubrity, and is believed to be quite as healthy as any part of the United States. European laborers have been engaged on the work during the whole summer, without scarcely a single case of sickness.

The contracts entered into in June last, for the graduation of upwards of 20 miles of this road, are rapidly progressing towards completion, and it will be seen by the annexed notice, that 30 miles more of the Road will be placed under contract on the 31st day of October next.

### GEORGIA UNION RAILROAD.

#### NOTICE TO CONTRACTORS FOR EXCAVATION AND EMBANKMENT, ETC.

Proposals will be received at the Engineer's Office in Augusta, between the 20th and 31st day of October next, for the excavation, embankment and bridging on 30 miles of the Georgia Railroad terminating southwest of Wrentham.

Contractors, unless personally known to the Engineer, must accompany their proposals with certificates or recommendations as to qualification and character.

Profiles of the line and plans of the different constructions on it, will be exhibited at the office after the 15th of October, and all necessary information in relation to the work afforded by the Chief Engineer or his assistants.

Augusta, Sept. 8, 1835. JAMES EDGAR THOMSON, Civil Engineer.

*A Dissertation upon the Running Gears of Railroad Carriages—illustrating some of their most important natural Mechanical Actions, inseparable thereto; and also describing a remedy for the evils set forth in the Dissertation, embracing principles not heretofore known. Also, a concise description of a Turning Platform for Railroad Carriages—a Curvature to turn corners of streets, wharves, &c., and Grooved Rails for the Curvatures, and the general use of the streets. Also, a newly invented Wrought Iron Wheel, for Railroads.* By JAMES STIMPSON.

In presenting to the notice of proprietors of Railroads my patent for an improvement in the running gears of railroad carriages, it may perhaps be proper for me to set forth the causes which called for this improvement, together with its advantages over any other mode now in use. In doing this it will be necessary to illustrate the true principles of the natural actions and mechanical motions of railroad carriage wheels as heretofore applied; there being several leading characteristics in their operations inseparably connected with them; some of which are prominent and powerful in their effects; and from the observations which I have been led to make, I am well convinced that they are not well understood, for otherwise their ill effects would ere this have been counteracted. I think I am warranted in my conclusions by the fact, that numberless alterations have been made on both sides of the Atlantic in the running gears of railroad carriages, with a view to overcome the difficulties that have constantly attended their operations.

To common observers the application and use of the running gears of railroad carriages appear extremely simple, and unattended with difficulties—merely round wheels running upon smooth iron rails—and at first sight one would be led to believe that such apparent simple and easy movements must necessarily operate without risk of damage either to the wheels, the carriage or the rails. But, in order to form a correct opinion upon this subject, it is necessary to observe that the natural course of running of four wheels of equal diameter is only in a straight line, when their axles are kept parallel to each other; and that whenever the railway deviates from a straight line, it becomes necessary, as wheels are now applied or geared to the carriage, to overcome a great proportion of their powerful adhesion to the rails. These facts have not been sufficiently taken into consideration by those who have hitherto endeavored to obviate the difficulties attending the passage of carriages over curves, crossings, crooks, and unequal undulations in railways; yet this adhesion, which must be overcome, very often constitutes the first great cause of all those difficulties, and renders it necessary, as will be hereafter explained, that the wheels should be made fast to their axles, especially when in the least conical; and that to prevent an extra liability of running off the tracks, their axles should be always confined in positions parallel to each other, while their flanges and cones are relied upon to keep them upon the rails, and cause them to conform to the course of the railway. It must also be observed, in order to a correct understanding of the subject, that when the wheels are fixed fast, and set true upon their axles, and their axles are kept parallel with each other, they cannot, without the use of great force, be moved in any other than a straight line, but are in fact,

as to any lateral movement, like four fixed props or legs—and it must follow of course that the force, that will be requisite to produce a lateral movement, must be more than equal to the resistance offered by the wheels to that movement; or in other words, sufficient to overcome their adhesion to the rails. Hence it will be readily perceived in what manner the stress of the carriage is brought to operate upon the naves, axles, spokes and rims of the wheels: for whatever power is used to overcome the adhesion between the peripheries of the wheels and the surface of the rails, must act upon all parts of the carriage and wheels, and of course react upon the axles, keys and naves in an inverse ratio of power proportionate to the difference between the diameters of the wheels and those of their axles. Now it is well known that this adhesion of the wheels to the rails is proportionate to the amount of surfaces in contact and the superincumbent weight to a certain extent; as has been illustrated by the experiments of Mr. George Rennie, Fellow of the Royal Society, London, and ascertained by him to be equal to forty-three per centum for seven hundred and nine pounds upon a square inch—or for every square inch of wheel and rail in contact.

By a calculation based upon these facts it will be found, that upon rails of the usual width, each wheel of a carriage, with a common load, adheres to the rail with a power of more than three hundred pounds. Now to produce an instantaneous lateral movement upon the rails, three of the wheels, as now applied and used, must slide, while the fourth will only have to oblique a little, or twist as it were, in order to conform to the direction of the others—and, by the way, this obliquing or twisting alone produces a damage to the rails and wheels equal to the force exerted by their adhesion together—and hence the great impropriety of using vibrating axles; for it is well known that they are made to oscillate or vibrate far beyond what is necessary to enable them to follow the true course of the road, besides that produced by every considerable impediment to motion under the peripheries of the wheels. I therefore propose to consider some of the most important effects produced by different modes of construction as they suggest themselves to my mind; and also the remedy.

#### *The natural power of adhesion of the Wheel to the Rails.*

The adhesion of one wheel being equal to three hundred pounds, that of three wheels will be equal to nine hundred pounds; therefore, a force more than equal to that resistance must be exerted by something in order to overcome it, whenever a lateral movement is required—and it must be borne in mind that this force, when one wheel has to move all the rest laterally, reacts upon the axles, keys, wedges, pins, or whatever may be used to fasten the wheels to the axles, with a power inversely proportionate to the excess of the diameter of the peripheries of the wheels over that of the axles—which is in most cases as twelve to one, and consequently amounts to ten thousand and eight hundred pounds at the nave of the wheel which produces the movement; and three thousand and six hundred pounds upon each of the others at their naves; and as roads are made in this country with frequent curvatures in different directions, and also with crossings from one track to another, when the power to be exerted is still greater than upon curves, this stress upon the axles and wheels is

acting and reacting almost constantly. Who then can be surprised at their early destruction?

#### *The means relied upon to change the direction of the Carriage.*

Let us now inquire what means are provided and used to effect a lateral movement, and to overcome the above mentioned resistance thereto; or in other words, to change the direction of the carriage and cause the wheels to follow the track without force; keeping in mind at the same time that from the causes before stated the wheels will run only in a straight line, and that they are held in that course by the parallelism of their axles and their power of adhesion—that is to say, a power of adhesion equal to three hundred pounds for each wheel at its periphery—and we find that a single cone is all that is relied upon to effect the object and to change the direction of the carriage when required.

#### *The amount of the adhesion of a cone compared with that of the tread of the Wheel.*

Let us next inquire what power one cone has to enable it to overcome the resistance of nine hundred pounds; which will be the resistance of three wheels when one cone acts alone, as before stated. Now, the power of adhesion being proportionate to the bearing surface and weight, up to seven hundred and nine pounds for each square inch of wheel and rail in contact, it follows that when a cone comes with its oblique angle in contact with a flat horizontal rail, its bearing surface is thus reduced to less than one fourth of that of either of the other wheels, which, at the moment when the cone begins to act, are upon their treads, its power of adhesion by its reduction of bearing surface is thereby reduced to less than seventy-five pounds. How can a power of seventy-five pounds, acting with no extraneous advantages, produce a change in the direction of the carriage, which is held in its straight course by a power of nine hundred pounds? It must be admitted that it is impossible. It follows then that the wheel on its cone must itself slide as much as its periphery exceeds that of either of the wheels running on their treads; and that it must continue to slide in that proportion until the vertical part of the flanch impinges against the edge of the rail, when the resistance to a change of direction in the carriage will be overcome by main force; that is, by means of the flanch. This will always be the case, unless the full size of the cone on the hind wheel, or a diameter thereof corresponding to that of the front wheel upon the same side of the carriage, comes in contact with the rail in time to act before the flanch of the front wheel is caused to impinge as aforesaid, for then the direction of the carriage will be changed by the joint action of the two cones, which have a leverage power over their two fellows equal to the length of the axles; and as the wheels upon their treads have only to oblique as they roll, and not to slide, they will yield to the action of the cones of their fellows.

When the direction of the carriage is about to be changed or turned from a straight line at the commencement of a curve, the fore and hind wheels on the outside of the curve cannot be in contact with the rail upon equal diameters simultaneously; consequently there must be a sliding somewhere until the hind wheel reaches the point where the curve commences and runs upon its cone to a diameter corresponding with that of the fore wheel: during all which time the strain upon the flanchings

and axles must be in proportion to the power of adhesion, &c., as before described. To this cause we may ascribe the early destruction of the wheels by the wearing out or indenting of the surfaces of their cones, and their constant tendency to work loose; and hence also the danger of using large wheels, unless the size of the axles be also large.

*The ill effects produced by the cone not being able to change the direction of the carriage in season, and also why it is not changed, &c.*

There is one extremely pernicious effect produced by the forcing of the wheels on one side of the carriage upon a higher part of their cones than is necessary before they are able to turn the carriage into the true course of the railway, to which I would call particular attention.

It is a well known fact, and has often been observed by travellers on a railroad, that the carriage will run from one side of the railway to the other, producing a kind of vibratory motion extremely unpleasant to the passenger. This is caused by the cone's not being able to change the direction of the carriage in season as before stated, and which is produced in the following manner: The wheels on the outside of the curve or crook at its commencement having been forced to run upon the very highest part of their cones by the causes herein before enumerated and explained, that is, want of power to change their course, they are in contact with an increased diameter to an extent that causes them to have a tendency as soon as they can act to turn a much shorter curve than that required by the railway upon which they are running: so that they necessarily cause the carriage to give a rank shear across the railway, whereby it is thrown upon the opposite side, and the other wheels forced upon the higher part of their cones on that side, also causing the carriage to take another shear back again; and thus it continues to vibrate from side to side, until all the wheels are brought to run upon that part of their cones or treads which adapts their diameters to the true course of the railroad. This vibratory motion will be produced, not only by curves and crooks, but by any unequal undulations or unevenness in the surface of one track of the railway, more than the other: thus, when it becomes necessary for one wheel to describe more space in the same time than either of the others—and from the causes set forth it cannot do it—there must be a dragging or sliding, which, whenever it does occur, an immense stress upon the wheels is produced, and a proportionately unnecessary wear to both rails and wheels.

*The improvement will allow the carriage to change its course of direction with perfect ease.*

One of the beauties of my improvement consists in its being a complete remedy for the evil consequences above set forth—for this improvement permits a single cone to change the direction of the carriage the instant it touches upon the rail at the commencement of a curve, and steer it precisely in the course of the railway, without causing the flanches to impinge against the rails, or producing any stress upon the axles, the wheels, or the carriage.

*The importance of the improvement at the crossings.*

*But when the carriage is about entering*

a switch at a crossing the importance of this improvement becomes immense; for it reduces the force of action or stress between the flanch and switch more than one-half; which is a great security against its running over the switches, and cutting away their top edges or breaking the flanch by the force of the blow.

*Large Wheels may be used, &c.*

By the application of my improvement, large wheels, if made in a proper form, may be used with safety where the tracks have no very short curves, and without increasing their weight or that of the axles beyond what would be their due proportion for their increased size, without any regard to the stress caused by adhesion, &c. With respect to the size of wheels, there is something to be said in favour of both large and small. Small wheels are lighter, safer in turning short curves, and easier to load heavy goods upon; but the smaller the wheel the less the bearing surface upon the rails: and the more rapidly will both wheel and rail be cut and worn away by the crushing of gravel between their surfaces, and also the metal itself. Small wheels make more revolutions in a given space, which creates more heat at the gudgeon and consumes the oil much faster. They also require more power to move them; and when passing over stones or any uneven places in the tracks, their concussions therewith are much more severe and injurious to wheels, carriage and rails, under equal speed, than when the wheels are large; and therefore they are more unpleasant to passengers both in their actions and on account of the noise they produce. When the roads are nearly level and tolerably straight, I should prefer wheels of thirty-six to forty-two inches in diameter for passenger cars that are intended for speed; and with the use of my improvement wheels of this size will cause less expense per annum, taking every thing into view, than smaller sized wheels.

When the wheels are composed partly of iron and partly of wood, and the stress naturally resulting to wheels made fast to their axles is properly considered, together with the effects produced upon them by the variations of the weather, the immense importance of the easement to motion, and relief from lateral or other strain, afforded by the application of my improvement, becomes the more conspicuous. Indeed for such wheels the use of this improvement is as indispensable as iron shoes are to horses upon hard roads.

The saving of power to a locomotive that would be made by the application of my improvement throughout a train of cars, is worthy of particular consideration; for without it in the same aliding of the wheels, which has been before spoken of, would appertain to each car, and thus the resistance resulting therefrom would be increased to a large amount by the number of cars in the train. It would thus require a proportionate increase of power to overcome this resistance; the exertion of which would produce extra stress upon the engine and boiler, and render it necessary to keep up the fire by an extra quantity of fuel, the excess of which heat is most certain to destroy the fire pipes. Now if the train of cars of the same weight can be moved over the same road with fifty pounds of steam instead of sixty, the saving is more in every respect than it would at first sight appear to be, and more especially in respect to the effects produced upon the engine, boiler, fire pipes, &c.; for the higher the pressure

of the steam the more power is requisite to move the valves, consequently they will wear out faster in all their connecting parts and get out of repair much sooner, and the more liable will the joints of the boiler, the pipes and all parts be to fail; and when the least thing does give way, all operations or movements are brought to a stand. The cost of the locomotives at the lowest estimation, embraces an item of expense which should leave no auxiliary to their duration and safety unnoticed.

*The bad tendency of loose wheels—they have no power to guide the carriage.*

As a means of avoiding the evils attendant upon the use of wheels made fast to their axles, resort has been had to wheels loose upon their axles—but to this mode of gearing there exist inseparable objections, which prove that the remedy is far worse than the evil; for the wheels themselves are rapidly destroyed at their naves and peripheries—the axles within the naves, with the collars and washers, as well as the rails themselves, are also subjected to an immensely increased wear and tear. Besides these evils there is a great loss of power, for loose wheels have not the power to guide the carriage, and the consequence is that their flanches will continually impinge against the edges of the rails, and thus the flanches and rails will cut each other in proportion to the power of adhesion which the treads of the wheels have to hold the flanches up to the edge of the rails. Nor have loose wheels the power to guide the carriage even when they are provided with cones upon their peripheries; for when the carriage approaches a curve, the front wheel, which first meets it, must run up upon its cone; the effect of which is, not to guide the carriage, but to impede its own motion, for being loose, it acts independently of its fellow wheel upon the same axle, and of course when its periphery is increased, instead of its acting as a guide to its fellow, it will merely describe the same space at the same time without turning so far on its axle. Its own motion is impeded, because in the very act of running up upon its cone, it runs as it were up-hill; and its diameter being increased, it is thereby made to sustain more than its due proportion of the weight of the carriage and load; both of which circumstances produce resistance to its advance. Nor will the direction of the carriage be changed until the flanch of the wheel strikes against the rail, and then the direction will be changed, but the flanch will grind along against the edge of the rail, producing an immense resistance to its own progress, and great injury to itself and the rail.

The facts must be obvious to all who have given best subject a thought. The wheel at the can have no more power of itself to change the direction of the carriage, than the amount of adhesion of the inside of the nave to the axle; which is of itself totally inadequate to the task.

But there are other ill consequences attendant upon the use of loose wheels, some of which I will endeavor to point out. Immediately after the flanch upon the front wheel touches the rail, that of the hind wheel will do the same—when their united resistance to motion will cause that side of the carriage to lag, and if there is any play in the joints of the transverse rails of the carriage where they join to the cheeks, it will cause the wheels on the other side of carriage, (which always run free when flanches of their fellow wheels are in con-

tact with the rail,) to get in advance, and thereby keep the flanges of their fellow wheels crowded up to the rail on the other side, by the course of their own direction, and keep them continually in contact therewith.

[From the Journal of the Franklin Institute.]

*On the comparative Corrosion of Iron, Copper, Zinc, &c., by a saturated solution of common salt.* By A. D. BACHÉ, Prof. of Nat. Philos. and Chem., Univ. Penn. To the Committee on Publications.

Gentlemen,—An inquiry was addressed to me some months since, by Mr. Joseph S. Walter, Jr., in relation to the material which would be most proper to be used for pipes to convey a strong solution of common salt to a pump intended to raise it, and for the material of the pump itself. From this solution it was intended to recrystallize the salt. The circumstances being of a somewhat complex character, I determined not to be satisfied with the indications of general theory, but to try the experiment, under the circumstances of the case, as nearly as might be possible. The materials in relation to which inquiry was particularly directed, were iron, copper, brass, lead, and zinc. Of these, the rapid oxidation of iron, when exposed to a solution of common salt, is well known; the corrosion of copper by sea water is also well known; the influence of the earthly muriates contained in the ocean prevents this case, otherwise very closely resembling that in question, from corresponding precisely to it, the common salt referred to containing these muriates only as impurities. Zinc does not decompose water readily, and oxidates very slowly, even when exposed to the combined action of air and moisture; it also ranks below sodium in the list of electro-positive metals; its chloride, however, is soluble. Lead is readily acted upon by the combined agencies of air and water, first oxidating, and then passing to the state of a carbonate; its place in the list of positive electrics is below zinc, and, of course, below sodium, which latter we should expect, therefore, to have the greater affinity for chlorine; the protoxide of lead, however, and several of its salts, interchange elements with chloride of sodium. The chloride of lead is insoluble, and hence the presence of soluble muriates acts as a protection against the corrosion of lead by water.

As the experimental results directly obtained may possibly prove of value to others than the estimable individual for whom they were to be applied, I have thought it right to put them on record.

The materials used were iron, copper, brass, lead, and zinc, the metals being as presented in commerce, and, therefore, probably not quite pure. They were prepared in rectangular plates, about two and a half inches in length, and three fourths of an inch in width, and varied in thickness from .03 to .07 of an inch. These were placed in glasses containing saturated solutions of common salt, rather less than one fourth of an inch in depth from the top of each plate being left exposed to the air. The vessels were left uncovered, and the evaporation of the water of the solutions was supplied from time to time during the exposure. The temperature in the room in which the vessels were placed, was not very different from 50° Fahr. during any part of the time.

After an exposure of about three weeks, the plates were removed from the solutions, and carefully washed and dried. Having been weighed before placing them in the solutions, they were now again weighed, and the loss of weight ascertained.

The iron plate was found covered with oxide of iron, strongly adhering to it in part, and in part deposited at the bottom of the glass containing the solution. There was upon the upper plate, and in the glass, a deposit of proto-chloride (white) of copper, colored by carbonate of copper, and a similar deposit upon the brass plate. The lead and zinc had been, to all appearance, very slightly acted upon; there was upon the latter a white deposit, probably of oxide of zinc.

The following table shows the amount of surface actually exposed to the solutions, the weight of the entire plates, and the loss of weight by the exposure. I have not reduced the weights used to grains, because the object is merely to obtain comparative results.

Material exposed.	Surface exposed.	Weight of plate.	Loss of weight.
Name.	Sq. inch.	Grammes.	Grammes.
Iron.	4.656	6.320	.312
Copper.	3.936	10.720	.053
Brass.	4.138	5.150	.029
Zinc.	4.572	6.115	.003
Lead.	4.762	20.080	.013

From the foregoing data I have calculated, below, the loss of weight, in grains, which a surface of forty square inches, or a plate of twenty inches on each surface, and very thin, of the materials would have suffered, and the relative loss by each material, referring to that which lost least, namely, the zinc, as the standard of comparison.

Material.	Loss of w'ght by 40 square inches of surface.	Comparative loss by exposure of same surface.
Name.	Grains.	Ratio.
Zinc.	0.40	1.00
Lead.	1.68	4.20
Brass.	4.31	10.78
Copper.	9.07	22.68
Iron.	41.27	103.18

The corrosion of the iron, with the same extent of surface as zinc, and exposed to a solution of common salt for the same length of time, is thus shown to be upwards of one hundred times [that of the zinc. The zinc appears to protect the copper in the brass, probably by rendering it electro-negative, and thus diminishing the affinity of the chlorine, which would otherwise destroy the copper.

Since the experiments indicate zinc and lead as the materials to be selected from those named, on account of the slight corrosion which they suffer, lead would obviously have been the material selected for the pipes to conduct the solution of salt to the pump, and zinc for the material of the pump, the selection depending upon well known properties of these metals.

The coatings formed upon both the lead and zinc, would protect the underlying surface from action, unless removed by mechanical force.

[From the Albany Daily Advertiser.]

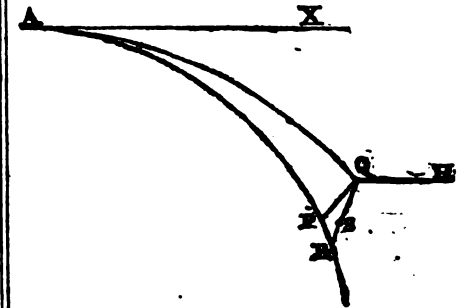

SANDUSKY and MAD RIVER RAILROAD.—On the 16th of this month, yesterday, thirty-five miles of the road were put under contract, and the residue of the distance, one hundred and eighteen miles, is preparing for contract. A great celebration was to take place this day in honor of the commencement of the work, and Gen. Harrison was expected to be present. Mr. Bell the Engineer-in-Chief, has received a request from the Leipsic and Dresden Railroad Company, to come immediately over, and take charge of that work.—This is the first instance of an American having received such an offer.

[For the American Railroad Journal.]

*On the Location of Railroad Curvatures; being an Investigation of all the Principal Formulas which are required for Field Operations, in laying Curves and Tangent Lines, to pass through Given Points.* By J. S. VAN DE GRAAFF.

(Concluded from No. 31, p. 483.)

Example 2. Let A R represent the curve of a graded roadway, and suppose A Q to be an approximate curve, traced 10 chains, of

100 feet each, with a modulus of curvature of 2° 45'. From the extremity at Q, suppose a normal line Q P to be measured 40 feet to the centre of the roadway at P. It is proposed to show a method of ascertaining the modulus of curvature which will trace the curve A R.

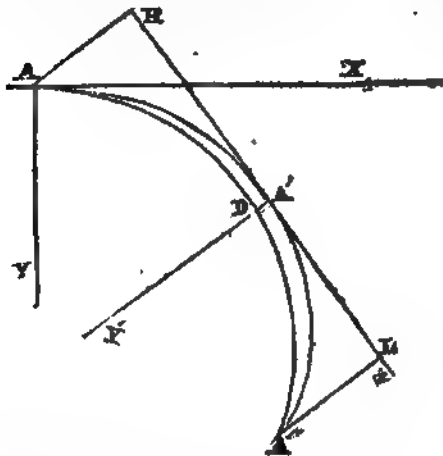

In order to obtain an approximate value for the new modulus of curvature by means of (XXXIX.), the given data are,  $T = 2^\circ 45'$ ,  $n = 10$ , and  $w = 4$ ; that is,  $T' = 2^\circ 45' + \frac{4}{10} = 2^\circ 45' + .4 = 2^\circ 45' + .229 = 2^\circ 45' + 13\frac{1}{2}' = 2^\circ 58\frac{1}{2}'$ . Now, if a new curve were to be commenced at the origin A, and traced agreeably to the modulus of curvature  $2^\circ 58\frac{1}{2}'$ , it would not touch the point P by a deviation of about 3 feet, as an accurate calculation will show, and a variation of even 6 inches from the true centre of a graded surface is frequently a matter of some consequence. If a small error be made in the modulus of curvature at the commencement of a curve, it is not a proper remedy, after the line begins to deviate a material quantity from the true centre, to make a new change of curvature merely to correct the former error; for such a method of operation not only shows a great want of skill, but it also multiplies the difficulties when the road at any future time may want adjustment. When, therefore, the approximate result,  $2^\circ 58\frac{1}{2}'$ , has been obtained, the next thing required to be done, by means of an instrument placed at Q, is to ascertain the true position of a point S, where the extremity of the 10th chain in the new curve would be situated, without actually tracing that curve upon the ground. The length and position of the line Q S may be correctly computed by means of (XXIII.), and (XXIV.); and then having measured the amount of error S R, to the centre of the roadway, the modulus of curvature required may be determined by means of (XXXIX.) For the given data will then be  $T = 2^\circ 58\frac{1}{2}'$ ,  $n = 10$ , and  $w =$  measured distance S R.

It will be here easily observed that there are two sources of error in the first result obtained from (XXXIX.) The greatest part of this error arises from the want of coincidence in the directions of the lines Q P and Q S; for an accurate calculation will show that in the present example, a difference of  $13\frac{1}{2}'$  in the moduli of curvatures corresponds accurately with a distance of 30 feet between the two extremities of the curves, which agrees with the distance

supposed in the first calculation, within one foot. But owing to the obliquity of the line Q S, a new curve laid from the origin A, agreeably to the modulus of curvature  $2^{\circ} 58' 3''$ , would intersect the line Q P at about 37 feet from the point Q, and therefore pass 3 feet from the true centre of the roadway.

Example 3. Suppose A A' and A' A'' to represent two different curves, connected together upon a common tangent at the point A', and selected in the field by tracing systems of rectangular lines agreeably to the method of co-ordinate axes as explained in art. 17; and let the numerical values of all the quantities remain as in the example given for that article. Now, in the place of these two curves, it is proposed to lay one continuous curvature from A to A'', if the ground about the intermediate point A' will permit such an alteration; and it is therefore required to know how far the new proposed curve A D A'' would pass from the point A'.

It is very evident that the co-ordinates A' H, H A, of the point A', taken with reference to the axes A' X', A' Y', are respectively equal to the co-ordinates x, y, of the point A', taken with reference to the axes A X, A Y. Hence, the given data for com-

puting the modulus of curvature of the proposed curve A D A'', by means of (XXII.), are the following:  $\alpha = A' H = 20.21$  chains,  $\beta = -H A = -12.47$  chains,  $x = 17.18$  chains,  $y = 10.24$  chains, and  $z = -63^{\circ} 20'$ . Therefore,  $\sin. T' = -2.23 \times \cos. 63^{\circ} 20' + 37.39 \times \sin. 63^{\circ} 20'$

$= -2.23 + 37.39 = 35.16$   
 $= \frac{32.412}{1408} = .02310$ ; or,  $T' = 1^{\circ} 20' =$  modulus of curvature which would trace the continuous curve A D A''.

The data for computing the distance A' D, by means of (XXXVIII.), will now be,  $n = 25$ ,  $T = 1^{\circ} 16'$ , and  $T' = 1^{\circ} 20'$ ; that is,  $w = .0175 \times 625 \times \frac{4}{60} = 0.75$  = the required distance A' D nearly, expressed in chains.

30. When two curves, having their respective moduli of curvatures represented in degrees by T and T', are laid from different origins upon the same tangent line, let  $\alpha$  denote the number of chains between the origins. If, then, the curve T be continued  $n$  chains, and the curve T' be supposed to contain  $n \pm \alpha$  chains, it is evident that the following formula will obtain for a reason similar to that in the preceding article, the quantity  $w$  denoting the same line as before:

$$w = qn^2 T \rightarrow q \cdot n \pm \alpha^2 \cdot T'. \quad (XL.)$$

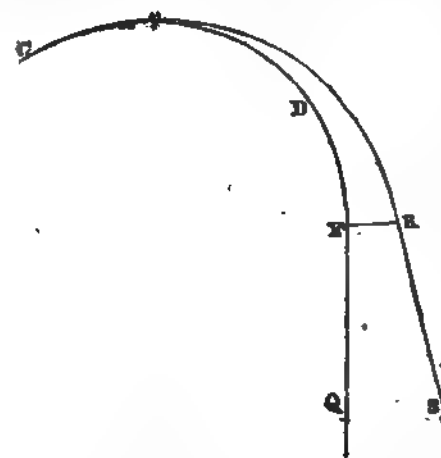

The expression thus obtained will be frequently useful in the field when short curves only are under consideration; and if it be supposed that  $w = 0$ , a formula may obviously be easily deduced which will correspond to (XIX.) by an approximation. For then  $n^2 T = n \pm \alpha^2 \cdot T'$ ; that is,

$$T = T' \times \frac{n}{n \pm \alpha^2}. \quad (XLI.)$$

This expression is remarkably simple, and will be very convenient for short curves.

31. Let C A D F represent a given curve, whose modulus of curvature is denoted in degrees by T, and let it pass into a tangent F Q at any given station F. Let also F R represent any small distance immediately on the right or left of the station F, and R S a straight line, whose inclination to the line F Q is denoted by a given quantity  $x^{\circ}$ . It is then proposed to determine a point A in the given curve C A D F, and the requisite change of curvature at A, in order to lay the curve A D F into the position A R, and the tangent F Q into the position R S.

Take  $w$  to represent the small given distance F R, and let  $n$  denote the required number of chains from A to F, and T' the required modulus of curvature of the new curve A R.

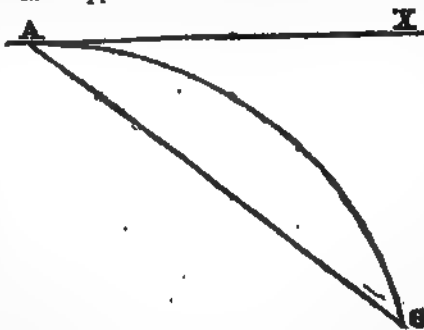

\* The two equations,  $z = 2n \cdot (T - T')$ , and  $w = qn^2 \cdot (T - T')$ , are furnished by means of (V.) and (XXXVIII.) respectively; and therefore, by eliminating  $n$  and  $T - T'$ , the following expressions will result:}

$$n = \frac{2w}{qz} \\ T - T' = \frac{qz^2}{4w} \quad (XLII.)$$

These formulas will be very convenient in the field when two short curves in reversion are to be connected by means of an intervening tangent common to both curves.

32. Suppose A X to represent a given

tangent line, and A a given point therein, which is designed for the origin of a certain

required curve to be laid passing through a given point G. Suppose, also, that the point G is visible from the origin A, and that the approximate distance A G is known. It is then proposed to find the necessary modulus of curvature, in order to trace the required curve A G.

By means of an instrument placed at the origin A, let the angle X A G be measured, and let its value be denoted by D'. It evidently appears from (II.) that the angle D' will contain the modulus of curvature as often as the curve A G contains chains. Hence,

$$T = \frac{D'}{n} \quad (XLIII.)$$

The expression thus obtained is extremely simple, and for short curves will be highly useful in the field.

HEAT.—For a long time, philosophers have supposed that meteoric iron is made hot while traversing the atmosphere. A curious experiment was resorted to by M. Bierley, a foreigner, within a few months, which may possibly be of some service to those engaged in similar pursuits. A bar of iron, heated to whiteness, was held against a strong current of air from the blowing apparatus of a forge. Singular as it may seem, the bar, instead of cooling, burned very brilliantly, throwing off scintillations in every direction. The temperature rather increased than diminished. This experiment makes it very certain that a metallic mass, whirled through the upper regions of the air, would become extremely hot and eventually sparkle, as many meteors do just before they fall.—[Scientific Tracts.]

Report to the Board of Directors of Bridges, Public Roads, and Mines, upon the Use of Heated Air in the Iron Works of Scotland and England. By M. DUFFRENOY, Engineer of Mines. Paris, 1834.

(Continued.)

REMARKS UPON THE NATURE OF THE COAL EMPLOYED IN THE FURNACES USING CRUDE COAL.

It results from the preceding description, that certain coals, those of Wales, are employed in their natural state, for the fusion of iron ore in the smelting furnaces in which combustion is sustained by cold air.

That a great number of others—the coals of Glasgow, for example—are also susceptible of being used in the crude state, when the hot blast is employed; but that, for some varieties, the transformation into coke appears still to be indispensable, whatever be the plan on which the iron is made. To appreciate the causes which produce these remarkable differences in the properties of these coals, I have collected samples of most of those employed in the works spoken of in this report, which M. Berthier has analyzed in the laboratory of the School of Mines, and the results of which he has communicated.

Coal employed in the crude state in the Welsh Iron Works. Cold Blast.

	Dowlais	Cyfartha	Pon-y-dan.
Carbon,	0.795	0.784	0.768
Ashes,	0.000	0.023	0.000
Volatile matters,	0.175	0.188	0.200
	1.000	1.000	1.000

The coal of Dowlais is lamellar, separating across the layers in smooth and brilliant plates. This coal is composed of two distinct parts, one brilliant, dividing into

small cubic fragments; the other, completely hard, fracture conchoidal, is nearly analogous to the Cannel coal.

These two varieties do not blend, but form in each strata small beds of greater or less thickness; the brilliant part greatly predominates. The Dowlais does not soil the fingers; it swells very little in coking, and does not cake; the ashes are perfectly white.

The coal of *Cyfartha* is rather slaty, or lamellar, but is composed, as the preceding, of the union of the brilliant and compact black parts, intimately mixed, like the quartz and feldspar crystals in granite.

These two varieties of coal act very differently; that having a brilliant fracture swells and cakes sufficiently, whilst the dull kind is dry, and does not change by exposure to the fire. It is probably this mixture that gives to the coal employed at the *Cyfartha* works the property of resisting more than any other the action of the blast, and the different movements which take place in the furnace; its friability is also due to this circumstance; but the bitumen, which exists in sufficient abundance in the shining coal, cements the different parts of this coal, and gives it a great solidity after having been exposed to the fire.

The coal of *Pen-y-danau* has the same properties as the preceding, except that the mixture of the two kinds is less intimate. These three coals, belonging to the coal basin of Wales, are very dry, and owe this property to the excess of carbon which they contain; they are analogous to the coal of Rolduc.

*Coals employed in a crude state in Furnaces worked with Heated Air.*

	Environs of Glasgow.			Staffordshire.		Derbyshire.	
	Clyde.	Calder.	Monkland.	Tipton near Wed'y.	Butterly.	Codnor Park.	
Carbon,	0.644	0.510	0.502	0.675	0.570	0.515	
Ashes,	0.046	0.040	0.014	0.027	0.030	0.030	
Volatile matters,	0.005	0.030	0.115				
	Water,	0.130	0.081	0.094			
	Gas, Tar,	0.166	0.330	0.215	0.300	0.400	0.455
	1.000	1.000	1.000	1.000	1.000	1.000	

The coal of the environs of Glasgow, employed in the Clyde, the Calder, and the Monkland works, present characters sufficiently marked, and of a composition very analogous, as seen by the preceding table.

This coal is usually dull, a little compact, hard, and does not crumble between the fingers; it presents, in its transverse fracture, a series of small lines, which gives a slaty appearance, though it does not, in reality, possess this quality. It is very well stratified, and the lumps cleave in flat fragments, of greater or less thickness: the surfaces of separation are almost always marked by black carbonaceous matter, which soils the fingers, and resembles charcoal in its fibrous appearance and dull color.

This coal is often traversed by extremely thin fillets of carbonate of lime, the direction of which is perpendicular to the layers, and sometimes pyrites is found.

The pieces of Glasgow coal submitted to analysis, softened but slightly; they cement together without change of form.

The coal of *Tipton*, which supplies the works of Lloyd & Forster, near Wednesbury, is slaty; it is composed of small beds, a few lines in thickness, separated almost always by an extremely thin bed of black carbonaceous matter, like charcoal. This substance is so abundant, that a piece of coal is rarely found at Tipton more than four inches thick, which does not present one or two layers of this friable ma-

terial. This coal, shining in its fracture, divides into small pseudoregular fragments; it is slightly tenacious, and swells but little in coking.

The coals in the environs of Derby are divided into two principal qualities, designated under the names of *Cherry coal*, and *Soft coal*; the first, which is the harder, resists the action of the fire better than the second. The furnaces of Butterly, which use heated air, consume the *Cherry coal* exclusively; this coal is slaty, and presents lines of dull black, which gives it a strong resemblance to the coals of Scotland.

The soft coals, employed principally for steam engines and puddling furnaces, are used also, at Codnor Park, for the roasting of ores. This coal is shining, slaty, and separates in pieces by very light pressure; it contains some thin portions of black and friable carbonaceous matter, already alluded to.

Notwithstanding the considerable loss which these two coals sustain by coking, they scarcely change their form; they swell and cake slightly, and their ashes are perfectly white.

*Coals that appear to require transformation into Coke, when employed even in Furnaces worked with Heated Air.*

	Birtly Works, near Newcastle.	Tyne Works, near Newcastle.	Apdala Works, near Newcastle, Staff'dshire.
Carbon,	0.605	0.675	0.624
Ashes,	0.040	0.025	0.035
Volatile matters,	0.355	0.300	0.341
	1.000	1.000	1.000

The coal consumed at the Birtly and the Tyne Iron Works comes from the mines in the environs of Newcastle-upon-Tyne; it is shining, and splintery; it does not soil the fingers, nor does it crush by a light pressure.

This coal is, in general, very pure, containing no veins of carbonate of lime, or pyrites; it is very adhesive, and swells much by the action of heat, so that the value of the coke exceeds that of the coal employed. I am assured at the Tyne Works, that they have tried in vain to work Newcastle coal in the crude state.

The coal of the *Apdala Works* is lamellar, shining and splintery in the direction of the strata; it divides into small quadrangular fragments; in the cross fracture, it presents large bands, perfectly smooth, and very brilliant. This is owing to the superposition of small layers, of which the nature is a little different; this coal is very adhesive, swells in the fire, and gives a light, silvery, but very solid, coke.

If we compare the composition of the different coals that we have examined, we perceive—

1st. That the coals employed in a crude state, in the furnaces worked with cold air, are dry, very carbonaceous, and, in fact, true anthracites.

2d. The coals, as those of Scotland and Derbyshire, which, though bituminous, serve, in a crude state, for the fusion of iron ore in the smelting furnaces worked with heated air, are, however, still dry coals.

3d. Finally, the fat, bituminous, adhesive coals, which change their volume, and swell by the action of fire, appear still to require a transformation into coke, to give advantageous results in the smelting of iron ore.

QUALITY OF THE PIG IRON AND BAR IRON OBTAINED IN THE WORKS USING THE HEATED AIR BLAST.

The iron for castings in Scotland bears

a less commercial value than that of Staffordshire. The first were quoted in the Liverpool market, in the month of July (1833) last, at 4l. 15s. sterling per ton, whilst the Staffordshire iron sold, at the same time, for 6l.

The difference between the price of these kinds, together with the prejudice generally entertained that the hot blast is unfit for the manufacture of iron, led some to doubt the advantages to be derived from the new method. The numerous observations I have made, tend, on the contrary, to prove that, for cast iron, at least, the products of the furnace working with heated air are superior to those of the cold blast. The less value of the Scotch iron is no evidence against this opinion. In fact, the Staffordshire iron has always been regarded as the most suitable for castings, and has always borne a higher price than that from most of the other parts of Great Britain; perhaps, also, the great difference in price between the Scotch and Staffordshire irons may be accounted for by commercial circumstances, for the Scotch now make iron much cheaper than others, and the production being increased almost one-third, by the employment of heated air alone, the iron masters have thought it to their interest to reduce the price of their iron, which they are enabled to do without loss.

It would be desirable if this important question could be decided by direct experiments; but for want of such, I will state the uses of these different products in the arts—uses which are, perhaps, as conclusive as experiments.

In the works near Glasgow, they make iron only for the foundry; I have seen the iron which they produce employed for the manufacture of castings, which require great strength and softness, to wit: steam engine cylinders, boilers, gas pipes, mill gearing, &c.

At Birtly, near Newcastle, and at Butterly, near Derby, I have also seen steam engine cylinders, pipes for water pumps, and fastenings for iron bridges.

I should state that the furnace of Torton, at the Fourchambault works, in the Nièvre, produces, since the use of this plan, gray iron, which competes in the market with that from England.

The iron manufactured from hot blast pig is also of very good quality.

At Codnor Park, near Derby, this iron is employed in the constitution of different parts of the steam engine, of chains for suspension bridges, and of straps and cross-bars in iron bridges.

The iron produced at the Tyne works is wrought into sheets, for steam boilers, gasometers, &c.

At Wednesbury, the iron is also of good quality, and serves for purposes which require great strength.

These different examples prove that, by means of the hot blast plan, as well as by the old mode, superior metal can be made for foundry purposes, and which is well adapted for conversion into wrought iron; but it must not be thought that, by means of this plan, the faults which result from the nature of the ore, or coal, can be corrected.

PROBABLE CAUSES OF THE INCREASE OF HEAT, DUE TO THE USE OF HEATED AIR.

I have remarked several times, in the course of this report, that the temperature of the furnaces worked with heated air appears to be higher than in those where combustion is sustained by the use of cold air; all the indications which are usually considered as guides for the working of the furnace unite in proving this assertion.

The scoria does not attach itself above the tuyeres; the color of the fire, in this part of the furnace, is so white as to be injurious to the eyes; the scorias, which are very liquid, flow with facility; the metal being hotter, can be cast directly into the most delicate objects. The quantity of ore in each charge is augmented in a great proportion, whilst the quantity of flux is decreased. This diminution in the proportion of melting is, of itself, the strongest proof of the increased temperature of the furnace; it indicates to us that the earthy matters find sufficient heat to fuse with a small addition of flux.

Probably it is to this excess of temperature that we should attribute the faculty of employing certain coals in a crude state, the transformation of which into coke appeared indispensable, at a less elevation of temperature.

In spite of these certain proofs of the increased temperature by the introduction of hot air into the furnaces, we cannot demonstrate its existence in a positive manner; but it appears to me that, to a certain point, a reason for this phenomenon may be given, by comparing that which passes in the furnace, by the constant introduction of air, to that which takes place by the mixture of two liquors of different temperatures, which we know will produce a mean temperature. The comparisons which I establish appear to me to be just, though the furnaces are in circumstances very different from the liquids having a given temperature, because the heat is reproduced without intermixture, by the combination of carbon and oxygen.

By admitting this cause of the augmentation of heat, it might be supposed to be very slight; on account of the great difference which exists between the temperature of the furnace, and that of the air which sustains the combustion; a difference that we have no accurate means of appreciating. I will show hereafter that this cause is not so feeble as might at first be supposed.

There is, I believe, another much more powerful cause, which it is impossible to estimate; it results from combinations, which could not be produced at the ordinary temperature of the furnace, and which are developed by the augmentation of heat due to the substitution of hot for cold air.

We see constantly, in our laboratories, examples of this phenomenon; substances which are acted upon slowly, and with much difficulty, by acids, at the temperature of the atmosphere, dissolved with facility when the liquor is slightly heated, and the combination formed often becomes itself a powerful source of heat. The operation of the smelting furnaces presents to us, perhaps, similar circumstances. The bitumen, and certain gases, which cannot burn at the temperature of the furnace using cold air, becomes ignited by the feeble augmentation of heat produced by the introduction of heated air; and the little smoke which passes out from the tunnel head when crude coal is consumed, and also the color of the flame, authorizes the belief that the bitumen, the hydrogen gas, &c., are almost wholly consumed.

This supposition naturally answers the objection that may be made, that, even admitting a certain augmentation of temperature by the introduction of heated air, there can be no diminution in the quantity of fuel consumed, because the diminished amount of fuel used in the furnace is compensated for by that required to heat the air.

We have stated that the quantity of air injected into the furnace could, by its great

mass, have the power of cooling it to a considerable degree.

This mass of air was raised in the Scotch works, before the adoption of the hot air plan, to 2800 cubic feet per minute, weighing 214½ pounds. The quantity of air injected in each day, therefore, may be estimated at about 140 tons.

The total amount of coal, mineral, and flux, does not exceed thirty-four tons; the weight of air, therefore, injected into the furnace, is more than four times that of the solid materials used in the same time.

We may conceive, therefore, that so considerable a mass, of which only a fifth part sustains combustion, thrown into the furnace at the mean temperature of the atmosphere, will produce a much greater refrigeration than when raised to the temperature of more than 600 degrees.

A circumstance which still tends to diminish, in a great degree, the refrigerating power of the air, by the use of the new plan, is, that the quantity of air is much less. In the furnaces of Scotland that we have taken for example, the quantity is reduced from 2800 cubic feet, to 2100 per minute, or twenty-five per cent.\*

We can calculate the influence of the introduction of air upon the heat developed each instant, by the combustion of carbon; but it appears impossible to appreciate the augmentation which results from new combinations, caused by the combustion of the bitumen and carburetted gases, because we cannot, in the present state of the science, estimate the temperature in the interior of the furnace; the few observations that precede, though not giving any idea of the real influence of the heated air, appear to me, at least, to establish that it is very considerable.

#### RECAPITULATION.

The details into which I have entered upon the greater part of the works using heated air, have, perhaps, prevented the reader from seizing the principal circumstances of the plan; I deem it, therefore, useful to recapitulate briefly—

I. In all the works, with the exception of one or two, its introduction has resulted in an increase of the products, an economy in the consumption of fuel, and of flux, as well as in the expense of labor, and incidentals.

II. These advantages have followed in the same progressive ratio as the temperature to which the air has been heated.

III. The production of metal has generally increased.

IV. The quantity of combustible matters burnt in the furnaces appears to be nearly the same where the heated air is used, as before with cold air; the daily consumption at the Clyde being eighteen tons of coke, to obtain six tons of metal; now it is eighteen tons of coal, to produce nine tons of metal.

V. The metal produced in the furnaces

\* The specific heat of water being represented by 1.0000, that of the atmospheric air is 0.2569, from which it results that a gramme of air at 322° Cent. (612° Fah.) the temperature at which the air is injected into the Clyde furnace, would raise 0.733 gms. of water to 100° (212° F.) supposing the air reduced to 10° (50°); and as the quantity of air introduced each minute is 124,770 gms., the heat which results from this mass is represented by 01,463 gms. of water, raised to 100°.

The charges at the Clyde works are now 34,416 kilogrammes of coal in twenty-four hours, or 23.00 kil. per minute, which, after deducting the waste by ashes, water, and gas, which escapes without being burnt, may be taken at a maximum of 20.30 kil.; the complete combustion of this quantity of coal would raise, in each minute, 1,465 kil. of water, from 0 to 100° centigrade; the increase of temperature which results from the temperature of the air at 322° cent., compared with that produced by the combustion of coal, would be as 92 to 1465, or one-sixteenth. This is the least ratio, the quantity of oxygen being insufficient to transform all the carbon into carbonic acid.

worked with heated air is generally gray, and fit for the foundry; nevertheless, this plan is employed with advantage in the works of which the pig iron is all, or in part, manufactured into bar iron, (Cudner Park, Tyne, Wednesbury, &c.) It is only necessary, for this purpose, to change the proportions of ore and fuel.

VI. In many works, the combustion requires much less heated, than it did cold, air; at the Clyde, for example, the same blast engine which served with difficulty for three furnaces, now blows four. The economy in motive force is not proportional to the diminished quantity of the blast, because a certain power is required to overcome the friction of the air in the heating apparatus, and the resistance which results from the expansion of the air by the heat. This last inconvenience is remedied by increasing the size of the tuyeres, their diameter having been increased from two and a half to three inches; the increased diameter of the tuyeres is also necessary to diminish the velocity of the current of air, when introduced into the furnace.

VII. When, as at Torthornton, a diminution in the quantity of air does not result from increasing the temperature, additional power is required to move the blowing machine.

VIII. The substitution of heated for cold air, in the fusion of iron ore, is marked almost immediately by a change in the nature of the metal, which becomes more carbonized; the charges descend more slowly, but the working is accelerated by augmenting the proportion of ore.

#### Relative to the Apparatus:

IX. The apparatus formed by joining pipes of large diameter, which receive the air, and of small pipes, in which it is heated, and dilated, appears to me to be preferable to that composed of a series of pipes, of great diameter; requiring a smaller space, being less costly in the construction, and consuming less fuel than the last named; besides, the temperature is not uniform in all parts of this apparatus, and a current is usually formed in the centre, of diminished temperature.

X. To diminish, as much as possible, the velocity of the air submitted to the action of the heat, and to avoid the resistance due to its expansion, it is necessary that the surface of the small pipes should be more extended than that of the large pipe which receives the air from the blowing machine.

XI. The interior capacity of the small tubes ought to be greater than the volume of air injected into the furnace; by this disposition, the air remains a longer time exposed to the action of heat, and acquires a more elevated temperature.

XII. From this last condition, the apparatus placed on the tunnel head appears to be of but little advantage to furnaces using coal; sufficient size cannot be given to it, to enable the air to remain long enough; to remedy this evil, the air is made to pass over another fire placed near the tuyere.

#### Relative to the Fuel:

XIII. The coals, very rich in coke, which are dry, and resemble anthracite, can be employed in a crude state, in furnaces working even with cold air.

XIV. The coals which contain a large proportion of volatile matters, (30 to 35 per 100,) but which are not very adhesive, and do not change form during combustion, serve, without being carbonized, to work in furnaces using air heated to 300° Cent.

XV. It appears, finally, that fat and bituminous coals, like those of Newcastle, which are fit for the fusion of iron, must, even with the hot blast, be transformed into coke.

[From the Journal of the Franklin Institute.]

**REMARKS ON COMPETITION PLANS FOR BUILDINGS.**—Every person, whose attention has been in the least degree directed to architecture, must have observed that, in the present day, the practice of procuring plans for buildings, by public competition, is becoming more and more prevalent. It is, perhaps, only of late years that this custom has been generally acted upon; and it is more commonly employed in the case of public buildings than in those of a private nature. When a public building is about to be erected, the parties advertise a description of what is wanted, offering, generally, a premium for the best plan, or for that which shall be finally adopted. Sometimes the successful competitors have nothing for their reward but that of being employed to conduct the work, for which they are paid as in ordinary cases. The plans submitted are, or should be, distinguished by a private mark, referring to a sealed letter sent by the competitor, in which his real address is to be found; and it not unfrequently happens that there will be from forty to fifty of such plans sent in, varying, of course, in equally numerous degrees of merit. Not a few of these drawings are the result of great labor, seldom occupying the time of the competitor for less than three weeks, and, if the building be very extensive, and the design well matured, having employed his sole attention for months together. The unsuccessful competitor, consequently, sustains a very serious loss; as he is not like the landscape or figure painter, who can carry his drawings to the market; the plans of the architect can be of no use but for the purpose for which they were originally intended. In fact, there cannot be, in any other profession, a competition which requires such a sacrifice on the part of the competitor, as in architecture; and, were this sufficiently impressed on the public mind, there can be no doubt but the labors of the architect would, in all such cases, be more duly appreciated, and, at least, rewarded with an impartial distribution of justice.

It may here be remarked, that sufficient time is seldom allowed by the advertisers for preparing the plans; for it will be confessed by every architect, that the faults of his composition will be easier detected by himself, after it has been laid aside for a time; we should say, therefore, that six months, at least, should be given, or even a longer period, according as the subject may require.

Although the system of competition in architecture is accompanied with no small expense to the parties competing, yet it cannot be denied that, when rightly conducted, it is conducive to the greatest advantages to the public, and is the only true method of eliciting the brightest talents of the country, especially when the premium held out is of sufficient value to induce proficient architects to come forward with their works; and, surely, the erection of a building which is destined to continue for ages, standing forth to posterity as an example of the architectural genius of our time, is not unworthy of the most assiduous attention. The practice has also a beneficial effect, in affording to a young architect facilities, which he could not otherwise possess, of pushing himself forward. Private competition plans are sometimes required, where the competitors are previously chosen out, and where all are paid a certain amount for their trouble, whether successful or not; this is certainly the most

liberal method, and should be adopted where the funds are sufficient.

In most cases where a decision is made on competition plans, the judges consist of men who are but indifferently qualified for the task, and whose fancy is easily carried away by a gaudy picture, the intrinsic merits of which they are incapable of appreciating; or, perhaps, by a design which has nothing else to recommend it but that of being so common-place in its character, as to be more familiar to their ideas than one of higher pretensions. Indeed, it is not to be supposed that men, whose pursuits of life are so totally unconnected with the subject, as never even to have led them to the inspection of a simple plan of a house, should be able to form a correct judgment of a number of elaborate drawings. It often happens, indeed, that the judges are so bewildered with the brilliant display before them, that they readily give way to some almost equally ignorant but pretending builder, to whom they look up as to the architectural oracle of their body, and who, it may be supposed, will not let slip such an opportunity of serving his own ends. This may, perhaps, be thought rather an uncharitable conclusion; but, certainly, there is but too much reason to fear that sinister influences have, in many cases, had an undue weight, and it is the particular object of this article to point out these grievances.

On such occasions as that we are just referring to, the most obvious method of proceeding, and that which would be the most entirely free from all suspicion of partiality, would be to name two or more architects, of acknowledged celebrity in their profession, (and residing at a distance,) to whom the plans should be sent for final decision. Care should also be taken by all judges, in forming their decision, to keep in mind the terms of the competition; for, although the value or cost of the building required by the advertisement be strictly attended to by some competitors, yet there are others who will disregard it, and will produce an elegant design, although its expense should be double the stipulated estimate, and who, by this trick, may blind the judgment of the umpires, and carry off the prize.

The undue means which are sometimes resorted to by competitors to forward their own cause, are disgraceful in the extreme: some have been known openly to carry about their designs, for the purpose of procuring votes, before the general election; some unfairly attach their names to their plans, (instead of using a private mark, as they ought to do,) in the hope that their friends may exert undue influence in their favor, or form a vain confidence in their own importance, which leads them to expect that the name alone will produce a favorable impression; and some have even been known surreptitiously to withdraw their designs from the exhibition, in order to add improvements which have been suggested by the designs of another: nay, such is the total want of principle, and disregard of justice to the competitors, shown in some cases, that an instance could be brought forward where one of the competitors was appointed the judge! This competitor judge most naturally gave his decision in favor of his own designs, and the unsuccessful competitors were dismissed with the most cogent and satisfactory argument, that "the judge was a man of such respectability, that he would not have chosen his own design, unless he had considered it the best!" Is it possible to conceive that language could be so sophisticated as to apolo-

gize for such conduct? Thus it is that nine out of ten competitions are decided, and thus are the architects treated who have spent a large portion of their valuable time for the benefit of the public. It must be acknowledged, however, that isolated cases occur, though few and far between, where no complaints of this nature can be made, and where fair play has been allowed to have had full scope. The Tron Church steeple, Edinburgh, erected, in 1828, by the architects Messrs. R. and R. Dickson, may be mentioned as an instance of fair competition; the choice of the plan reflects the highest credit upon the then magistrates of the city, who made their election from a great number of designs. Considering its cost, this steeple, for aptness, originality, and picturesque beauty, can scarcely be surpassed in any country. It would not be easy to cite many instances of the same kind in Scotland, but we may mention another, viz.: Burns' monument at Ayr, by Thomas Hamilton, Esq., of Edinburgh. This is an exquisite gem of Grecian architecture, of which school its tasteful architect is a distinguished disciple. Finally, it is evident that the grievance here complained of, and which calls so loudly for redress, is in no way amenable to the civil law, unless in such a case as we have before hinted at, viz.: where the judges do not abide by the advertised terms of the competition. Even in such cases, we are not sure how far they lay themselves open to have their proceedings legally called in question, so that an appeal can only be made to the moral rectitude of society; and we have no doubt that the evil only requires to be fairly exposed, to be, in time, totally eradicated.

Edinburgh, October, 1834.

**OBITUARY.**—The Orang Outang, or wild man of the woods, which has lately attracted such crowds at Peale's Museum, died on Saturday at 12 M. after an illness of one week. In order to ascertain the cause of his death, a *post mortem* examination was held in the Lecture Room of the museum.—[Transcript.]

On Friday night, the tiger in the menagerie in Sixth-street, Philadelphia, contrived to escape from his cage, and having a good appetite, he beset the little Shetland pony that belonged to the same concern. Having despatched the horse, he turned to one of the men belonging to the establishment, and would have torn him to pieces but for the timely interposition of some of the attendants. The beast was killed and the man saved.—[Transcript.]

[From the Cincinnati Gazette of 11th inst.]

**ANOTHER STEAMBOAT ACCIDENT.**—The *Hero*, Capt. Page, struck a snag near Sandy, on Tuesday last, and immediately sunk to the hurricane deck. She had a heavy load of dry goods on board, principally for this city and Louisville. The *Hero* had laid by for fog, which had partially cleared off when she put out; but it suddenly became so dense, as to obscure the shore, and the nearest objects. Her passengers were brought down by the Hantress. No loss of life, or any serious injury, except to the boat and cargo. The boat can be raised again, when the water falls a few feet.

**EXPLOSION.**—On Thursday, 9th inst. at 9 o'clock in the forenoon, an explosion took place in one of the graining mills in the powder factory of D. Rogers, Esq. near Newburg. The mill had not been in operation for more than a week previous to the time of the accident, which can in no feasible manner be accounted for. There were, fortunately, only two persons in the building, who were both killed, viz.: Henry Glessing, a young unmarried man, and John Sutherland, a married man, but without any other family. The former was thrown a considerable distance into the field adjoining, and bore but slight marks of external injury—the latter was dreadfully mangled. The explosion was heard at Fishkill, and for several miles around.—[Journal of Commerce.]

AGRICULTURE, &c.

*On the advantages to be derived from the establishment of an Agricultural Professorship.*

To the Editor of the Farmer's Register:

Barboursville, July 23, 1835.

Sir,—It has been a settled conviction on my mind for years, that a professorship of agriculture—a pattern farm, and such a paper as yours, united therewith, would be productive of incalculable benefit to the commonwealth. The space of a letter is too confined to admit of one half being stated. Suffice it to say, it would elevate the science—add dignity to the pursuit—call off from encumbered vocations a portion of the mind of our citizens now lost to the community—present a rallying point for all the scattered information of the land—reduce to the test of experiment every theory plausible enough to justify it—by the same standard to prove the value of every discovery or improvement—promote economy by causing one experiment for many—a certain and rapid communication, through the State, of the results—furnish a sure means of ascertaining the nature of our climate—the quantity of rain falling in the year—the seasons when drought most generally prevails—and by consequence, furnish data to guide the husbandman in the cultivation of crops, both as to time and kind. But I must stop—for I find no end to the advantages that would result from such an establishment. Let me, however, add one more. All these things are to be done before the youth of Virginia—the future men of the commonwealth, destined eventually to influence her destiny. A portion of these, selected from every part of the state, (say one to each congressional or senatorial district,) of promise, but unable, from poverty, to educate themselves, to become the adopted children of the state, would be able by alternate labor and study, alike to keep up the farm, and to improve themselves. Indeed, it is worthy of the profoundest consideration, whether every student of the University would not profit by a few hours work daily, in the proper season. These being my views, I submit to you whether it does not behoove the tillers of the earth to make an effort to induce the legislature to attend to their neglected interests. How is this to be done? I answer, as every other sect effects every thing by conventions—to that alternative we must also resort. What say you to such a convention, to meet in Richmond the first Monday in January? Let any one who feels an interest in the object attend. Let each agricultural society in the State be represented there. If it be asked what good can come of it, the answer is, let us try it. A free communion of the intelligence of the land cannot be altogether unproductive of good fruit. Apart from what can be done by such a convention on its own means, an appeal may be made to the legislature under the weighty sanctions of their united wishes, to do something for us. If the view which I suggest is esteemed

impracticable, they may incorporate an agricultural society in each congressional district, and award a small sum to each, to be distributed in premiums, after the manner of New-York and other states.

But it is objected that it will cost something. Have we not as a class offered our fleece annually, without a murmur, to be appropriated to other improvements? Is it unreasonable that in turn we should require a small portion of our own to be applied to our peculiar benefit? A small portion of the interest paid annually by the University, would in a few years put our scheme completely in operation, and I verily believe after that it would be able to support itself. However, all these things might be discussed in convention, and digested in a form that would be most acceptable. And I may be permitted to add, that for once we should have a convention whose sole object would be the good of the country—a spectacle so singular in these times, that it could not fail to be as consolatory as the oasis to the weary traveller of the desert.

If you agree with me on this point, you can greatly promote the object by inviting the meeting in your journal. If I thought my name would be of any service, you would be at liberty to use it with my remarks. But I fear not. However, do as you please. I have it much at heart to do something. Better heads than mine may suggest better plans, to which I will most cordially submit.

Accept assurances of my high consideration.  
JAMES BARBOUR.

From the Farmer and Mechanic.]

**TO DYE WOOLLENS.**—Last September I was at the exhibition in Burlington, Kentucky, and was much pleased at the spirit shown by the ladies of that neighborhood, in manufacturing so many excellent articles of domestic manufacture for exhibition. For this they deserve great credit; but I observed that in many articles, particularly the carpeting, that though the spinning and weaving were well done, in most of them the coloring was deficient, which I attribute to their not having proper instruction in that branch of the business, and have therefore made out the following directions for dyeing, and I hope you will publish it for their benefit, viz:

Woollen yarn may be dyed yellow by boiling it for an hour with about one-sixth of its weight in alum, dissolved in a sufficient quantity of water, then plunging it, without being rinsed, in a bath previously prepared, by boiling black oak bark, (as ground for tanners,) in water; the yarn is to be boiled in this, and turned until it has acquired the wished-for shade; the oak bark should be strained out of the liquid. It would be of considerable advantage to add one ounce of cream of tartar to each pound of alum used. After the yarn is dyed it should be well washed in several changes of water.

Woollens may be dyed blue by dissolving one ounce of good indigo in four ounces of oil of vitriol (sulphuric acid.) This must be done in a glass or stone vessel, powdering the indigo before it is mixed with the

vitriol; to the solution one ounce of dry pearl-ash is to be added. The yarn must be boiled in a sufficient quantity of water with one ounce of alum, and one ounce of cream tartar, to every six pounds of yarn; the boiling to continue at least one hour; it is then to be thrown, without rinsing, into a water bath containing a greater or smaller quantity of dissolved indigo, according to the shade wished for. In this bath it must be boiled, until it has acquired the color, and then washed.

Green can be dyed by adding as much of the dissolved indigo to the bark bath, prepared for yellow, as with the proper shade. The cloth having been boiled with alum and tartar, as directed for yellow, is to be put into the mixture, and the same method pursued as directed for dyeing that color. I would observe that there are many methods of dyeing blue, many of them practically known in the families of most farmers, and therefore will probably be preferred by them, but this method is most certain and most convenient for obtaining a fine green.

A good red may be obtained by boiling Nicaragua wood in water until the color is extracted, and then straining the liquor; the yarn having been prepared in alum water as previously directed, is to be boiled in it in the same manner as directed for other colors. Different shades may be produced by adding a little copperas.

Wool may be dyed black by the following method—first prepare a bath by boiling one pound of black oak bark, to every ten pounds of yarn, in a sufficient quantity of water. In this bath the wool is to be boiled for two hours, it is to be put into a bath composed of three-fourths of a pound of copperas, and two pounds of logwood, for every ten pounds of yarn, and a sufficient quantity of water; in this it must be kept for two hours more, at a scalding heat, frequently taking it out and exposing it to the air during the operation.

A MECHANIC.

[From the Southern Agriculturist.]

**RARE AND VALUABLE SEEDS AND STINGLESS BEES.**—We introduce to our readers the promised letter of Henry Perrine, Esq., Consul at Campeche. It will be remembered that in our last number, we acknowledged the receipt from this gentleman, of a hive of stingless Bees; they have been committed to the care of one, whose public spirit will cause him to regard himself as the husbandman of the community in which he lives; he will second the patriotic efforts of the Consul at Campeche, in conferring upon us a gift so interesting. This has not been the first evidence of the liberal interest felt by Mr. Perrine, in promoting the introduction of valuable products from abroad; and if our motives were purely selfish, we still might very consistently wish, what we now offer in pure thankfulness, a renewal of his health, and of his public office in some other quarter of the globe.

"Consulate U. S. A.  
Campeche, June 18th, 1835.

To the Editor of the Southern Agriculturist:

Sir,—Although on the eve of my return to the United States, yet as the schooner

Carolina Brutus, now returning to Charleston, is the only vessel which, during eight years, has afforded a direct communication between this port and yours, I avail myself of the few minutes allowed me to send you a few products of this peninsula.

I name first, a paper of the beans, which produce the root here, called Jicama (*Dolichus bulbosus*?) as the success of Mr. Skinner, in Baltimore, justifies the belief that in your latitude it will flourish and become a valuable addition to your horticultural, or even agricultural resources. Next you will find a paper of the four-winged pods of another leguminous plant, which rapidly grows into very ornamental trees (*Piscidia Campechana*), whose wood (here called Habi) is as highly prized for ship building in Campeche, as is the live oak in the United States, or the teak in the East Indies: and has the much greater merit than both, inasmuch as he who plants the seed may profitably cut the timber. I also send a small quantity of nankin colored, and of kidney shaped seed cotton, which will speak for themselves in a cotton growing country like South Carolina. Last, and greatest in my estimation, are the samples of the *foliaceous fibres* of Yucatan and of Goazacoalcos, (the coarse called Henequen, and the fine called Pita in the ports of Mexico) and of the leaves of the Agave, and of the Bromelia, from which they are extracted. Your own Elliot, in his Botany of South Carolina, long since anticipated the cultivable value of the foliaceous fibres of your indigenous *Yucca filamentosa*. I have not the time to give even an epitome of the relative advantages of the Agave Henequen and of the Bromelia Pita, for extensive cultivation in the most sterile districts of the south, the former in sunny plains and the latter in shady woods, where it absolutely usurps the place of the common worthless undergrowth. I still, however, persist in my conviction, that the production of foliaceous fibres in the most barren soils of the south, will be much more profitable than the cultivation of your present great staple of capsular fibres in the most fertile loams, and hope that during my travel after health this summer, I may take some active droselytes. By-the-by, you must not mistake the present samples of the fibrous leaves to be good ones, as in truth, they are the refuse of a number collected two years ago, which have been tossed about in the dust.

While writing the above, an Indian has returned with the hive of stingless Bees, which I feared would not arrive in time for Captain Kerrison, who is hurrying me to conclude this unpremeditated epistle.

Very respectfully, your ob't serv't,  
HENRY PERRINE."

The seeds mentioned, we will distribute among our friends who wish to attempt their cultivation. The *Piscidia Campechana*, we presume is the same as *P. Carthageniensis*, a variety of the Jamaica Dogwood, the generic name is derived

from its power to intoxicate fish. It is said that the fibres of our *Yucca filamentosa*, are the strongest of any known plant. It is familiarly known as the silk root with which woollens are washed, but is not applied by us to any other use. We should suppose that it must surrender its pretensions as a fibrous plant of value, to the Bromelia sent by Mr. Perrine. The specimen of this, at our office, is well worth examination, and is by far the most interesting of the plants he mentions. His description of the locality in which it delights, will at once bring to mind the extensive body of pine land in Georgia, which spreads from the sea shore over half of the State, now infested with endless tracts of stunted palmetto. How can this have escaped the attention of Mr. Spalding, of Sapello? His name is connected with the first culture of many of our staples, and this is a new opportunity of identifying him with the prosperity of Georgia.—[Ed. So. Agr.]

THE CULTURE OF COTTON.—The following remarks are from a source which give them a title to consideration.—[Boston D. Adv.]

"The crop of cotton is turning out much larger than was expected, and will be quite equal to the consumption at present prices. There is no doubt it is very much short of what it would have been, had the season been propitious; nor can the reports of its disasters made by so many of the most eminent men in the country be rejected, from which we may infer that the progressive annual increase of cultivation was much greater than supposed, and that had the season been favorable, the quantity raised would have far exceeded the most extended estimates.

"The production of cotton has more than doubled every nine years since it became a staple of the United States. In 1816, nearly all Alabama, Mississippi, and Arkansas, and many of the most fertile districts of Georgia, Louisiana, and Tennessee, were a wilderness, the hunting grounds of savages. Florida was a retarded Spanish colony, and the whole negro population in the lower valley of the Mississippi did not exceed sixty thousand. But such has been the unparalleled prosperity of the country, that the Indians have nearly all dispersed out of these regions, the terrors of emigration into the wilderness have vanished, settlements and civilization have extended over the country, canals, railroads, and other useful improvements are rapidly progressing, and banks and factors are ready to grant facilities to planters to extend their estates—which leads to the belief that the annual increase will be greater than ever it has been, particularly as there is an almost unlimited extent of suitable land, and the migration far greater than ever it was from the northern slave states into the fertile cotton districts, where the labor of the slave is so much more valuable than in the grain states, and as cotton at eight cents per pound is the most profitable agriculture in this or any other country.

To those unacquainted with the culture of cotton, it is worthy of remark, that it is the most certain crop planted. The harvest begins in August and ends in February, or when the land is ploughed for a new crop. The bounds of latitude are about 36 degrees; therefore, by far the greatest part of the globe affords a suitable climate. The last crop in the United States is considered by the most experienced planters the shortest return for the labor, of any since its cultivation became an object of this country. The bordering province of Texas has a large extent of the finest cotton lands in America; but as it belongs to the Mexican Republic, where slavery is only tolerated under the name of apprenticeship, the production of cotton there may not increase so fast as many anticipate. It has land capable of producing more cotton than is now raised in the whole United States. The exports last year were about 1000 bales—this year they will be about 3,500, next year they may ex-

ceed 8000 bales; and should the climate prove favorable, to white laborers engaging in agriculture, there is no doubt that indigent Germans and other laborious orders of the white race will emigrate and increase the population in a few years to an extent capable of raising a large quantity of this important article.

The Slave population of the United States, by the census of 1800, was 893,041. In 1810, 1,191,364. In 1820, 1,538,038. In 1830, 2,009,043 Slaves and 319,599 free Blacks; which shows they double in about twenty-five years; therefore, according to the ratio, the Slave population at this time is about 2,300,000; to which add the free blacks, and it shows the colored or African race in the United States to be equal to the whole population at the commencement of the Revolution, or nearly the same as the present population of Scotland.

Our statistical estimate shows about 1,100,000 Slaves residing in the Cotton districts, from which number we deduct one half for superannuated, juvenile, mechanics, house servants and others that do not work in the field, and it shows a force of 550,000 field hands engaged in raising Cotton, exclusive of a number of white persons and free negroes. The reduction of one half on the slave population is the usual allowance that statistical computators have made to ascertain the effective force of field hands; and as this data has been formed on the slave population in the older or Northern Slave States, where the habits and customs are more indulgent than in the new and more enterprising regions, it leads to the belief, that the proportion of field laborers in the new States is greater than in the old. We should add our statistical estimate, but the document is too voluminous for a commercial letter.

In the Atlantic States, North Alabama and Tennessee, 2 1-2 to 3 1-2 bales to the field hand is the usual return. In Louisiana, Mississippi, and South Alabama, from 4 to 10 bales is the return—besides raising provisions; but in some situations, where the return of cotton is the greatest, some of planters find it more for their interest to purchase provisions than to raise them. The quantity of clean cotton made per annum, varies from 150 to 600 pounds, each hand cultivates about 10 acres.

In 1825, it was estimated that the number of slaves engaged in the cultivation of cotton, was 230,000 field hands. The export of 1825-6, was 710,000 bales, or more than double that of 1816-17. This year we estimate the force at 550,000 field hands, but the increase has been much the greatest in the most productive districts, which by the usual rate of return, would make a crop of over 1,800,000 bales.

Again, if we take the increase as doubling every nine years, it would give a crop for 1835-6, double that of 1826-7 (937,000 bales,) or over 1,800,000 bales, which nearly corresponds with the statistical estimates.

These views exhibit a surprising increase and a capability of producing to an extent few are aware of.

It takes at least two years to bring lands into crop. The highest prices of 1817-18, exhilarated the production which came forward in 1821—that crop being over 40 per cent. more than the crop preceding it. The reduction of prices in 1819 deterred such rapid extension until the advance in 1824-25, which gave an extraordinary stimulus to the cultivation, which caused the exports of 1827 to be near 33 1-3 per cent. more than the year preceding. The advance in price during the last three years, (and the facilities as noticed in the same paragraph,) would have no doubt showed a large increase this year, had it not been for the unparalleled injury done to the crops; and therefore taking the increase of the periods quoted as an example, it leads to the conclusion that this year the United States is capable of raising 1,800,000 bales, if the season should be propitious.

The growing crop is very promising, and the high prices have stimulated the cultivation so much beyond its usual progression, that should the season continue propitious, there will be a quantity raised far greater than almost any suppose. Those who hold high priced cotton, should consider that the new crop will be at hand in a few weeks, and that it may prove much larger than almost any contemplate, and that present prices may fall 50 per cent. without being as low as they had been when trade was good and stocks moderate.

NEW-YORK AMERICAN.

SEPTEMBER 19—25, 1835.

LITERARY NOTICES.

AN EXPOSITION OF THE MYSTERIES OR RELIGIOUS DOGMAS AND CUSTOMS OF THE ANCIENT EGYPTIANS, PYTHAGOREANS, AND DRUIDS.—ALSO, AN INQUIRY INTO THE ORIGIN, HISTORY AND PURPORT OF FREE MASONRY; by JOHN FELLOWS, A. M.; New York, Printed for the author, and sold by GOULD, BANKS & Co.—“This book” says a capable correspondent who took the book from our table, and returned it with this notice, “treats a subject of great interest to the learned world. It is composed of translations from eminent writers, on the subject of the Ancient Mysteries, accompanied with notes by the author, and dissertations upon the ceremonies of Masonry, their relation to the rites of the Egyptians, and those practised in the celebration of the mysteries of Eleusis. The work appears to us inartificial and confused, and wanting that unity of effect and consistency of design in the conduct of the argument, which a profound knowledge of the original sources, and a practised pen would have imparted. The author does not appear to have seen some of the modern works on different branches of his subject, or to have pursued the striking analogies which the Phallic worship, and the practices of Manichæism, might perhaps have afforded. But still the work is characterised by industry, and the love of truth, and we think will afford to the reader, many new ideas, and lead to some startling inferences. It is curious that a work on the same subject, has just appeared in England, which is highly spoken of, but which has not reached us.—We have no time to follow the writer through his book; or to give any quotations from it. His object is to prove, that in the higher mysteries of Greece and Egypt, the unity of God was taught to the initiated, in opposition to the Polytheism which formed the debasing creed of the common people.—Of this there has long been no doubt. That Masonry also inculcated the existence of one Supreme Governor of the Universe—that its emblems are mainly derived from Egyptian Mythology, from the worship of Isis and Osiris, and the strong astronomical character, which every thing Egyptian bears. And so far as we can judge, we think the writer has been successful.

Mr. Fellows has made, in this volume, allusions to the fact of many of the ceremonies and observances of the Christian church being of Pagan origin. This is a very interesting subject, but by no means a new one. We recollect reading a work some years ago, by Mr. Blunt, a Fellow of Oxford, in which he showed clearly, at least to us, that the ceremonies of the Church in the island of Sicily, and particularly of the Cathedral of Syracuse, were almost identical with the honors formerly paid there to Ceres. There is another fact not mentioned in this work, that the peculiar insignia of the festivals in honor of Bacchus, were engraved on the *abacus* of the Grand Master of the Knight Templars. After all, perhaps learning of this description is more curious than profitable—more suited to the closets of the learned, than the consideration of the humble and devout Christian.

THE STUDY OF MEDICINE; by JOHN MASON GOOD. 6th American from the last English edition—with Notes, by A. SIDNEY DOANE, A. M., M. D., &c. &c. 2 vols. 8vo. New York, HARPER & BROTHERS.—This is really a mighty publication—two stereotyped volumes, of double columns and of seven hundred and fifty pages in each volume. The mere pecuniary outlay in such a re-print as this, with the numberless additions—which in this

instance, are improvements—by the accomplished American editor, cannot fall short, we presume, of twelve or fifteen thousand dollars.

We cannot doubt, however, that it will prove a judicious outlay. Dr. Good's work has been for years, a text book in England, and in this country—but the excellence, and the great recommendation of this edition, to American students and medical establishments, is in the notes due to the research, ability, practical knowledge, and perseverance of the American editor, Dr. Doane—a gentleman, who by diligent study and assiduous application, has eminently qualified himself for the task—greatly above the reach of any ordinary capacity or acquirements—of *fitly* editing, and illustrating by notes, such a standard work as this.

The advantage, and the need among us, of an edition thus enriched, are to us modestly glanced at in Dr. Doane's preface.

“It was with extreme diffidence, and with no little dread of appearing presumptuous, that the American Editor assumed the responsibility of adding notes to a work characterized by such profound learning and deep research; but he was encouraged by the consideration, that although “The Study of Medicine” has been used as a text book, for several years, in this country, and is thought to be indispensable to every American Library; it contains but few allusions to American practice; while, some forms of disease peculiar to this country, and the contributions of American Physicians to Physiology, Pathology, Therapeutics, and the *Materia Medica*, are generally unnoticed in it.”

This, it will be admitted, are all sufficient reasons for undertaking the task—and, in recommending the book as one of great general interest, and information, to persons in, and out of, the medical profession, we repeat, that so far as our knowledge enables us to judge, Dr. Doane has performed his part, with remarkable ability and discrimination.

FOSTER'S SYSTEM OF PENMANSHIP, &c. &c.; by D. B. FOSTER, Teacher of Writing and Book-keeping, &c. 1 vol. Boston, PERKINS, MARVIN & Co.—We like the evidence afforded by this title page, that the writing master is not above his business, or his proper title, and that instead of calling himself Professor—as is the wont now-a-days of all teachers, from the dancing, fencing, or boxing master, up—he qualifies himself simply as teacher. We do not doubt the rules laid down in this treatise are sound, and will lead, if duly followed out, to excellence—though they are rather calculated to dispel the dreams of those, who flatter themselves with the possibility of learning the art and mystery of writing, in twelve hours. Apropos, however, of this treatise, and of the anti-angular Mr. Bristow—whom it treats as not of the regular faculty—it is only fair to say, that within a few days, a clever young lawyer of our acquaintance, who, to cure “a c—d cramped hand,” had put himself under the teaching of Mr. Bristow—called upon us full of delight at the result, and with an earnest request that we would publish a glowing, though somewhat *lengthy*, recommendation he had indited, of “the anti-angular system.” He must take this notice as a substitute therefor.

NUTS TO CRACK, OR QUIPS, QUIRPS, ANECDOTES, &c., OF OXFORD AND CAMBRIDGE SCHOLARS; by the author of FACETIÆ CANTABRIGIENSES, &c. : 1 vol. Philadelphia, CAREY & HART.—There is some fun and amusement in this little volume, though too scholastic some of it, we apprehend, for the medium of this country. We take from it, however, some extracts.

THE VALUE OF A SYLLABLE.—“The masters of olden time at Athens, and afterwards at Oxford, were called *Sophi*, and the scholars *Sophistæ*; but the masters taking it in scorn that the scholars should have a larger name than they, called them-

selves *Philosophi*,—that is, lovers of science, and so got the advantage of the scholars by *one syllable*.” Every body has heard of Foote's celebrated motto for a tailor friend of his, about to sport his coat of arms,—“*List, list, O list!*” But every body has not heard, probably, though it is noticed in his memoir, extant in Nichols's *Literary Anecdotes*, that the learned Cambridge divine and antiquary, Dr. Cocks Macro, having applied to a Cambridge acquaintance for an appropriate motto to his coat of arms, was pithily answered with “*COCKS MAY CROW*.”

Every Cantab remembers and regrets the early death of the accomplished scholar, Charles Skinner Mathews, M. A., late Fellow of Downing College, who was “the familiar” of the present Sir J. C. Hobhouse, and of the late Lord Byron. He was not more accomplished than facetious, nor, according to one of Lord Byron's letters, more facetious than “beloved.” Speaking of his university *freaks*, his lordship says, “when Sir Henry Smith was expelled from Cambridge, for a row with a tradesman named “*Hiron*,” Mathews solaced himself with shouting under Hiron's window every evening—

“Ah me! what perils do environ  
The man who meddles with *hot Hiron!*”

CLASSICAL JEU D'ESPRIT.—Vere one day asked his learned college contemporary, Dr. John Taylor, editor of Demosthenes, “why he talked of selling his horse?” “Because,” replied the doctor, “I cannot afford to keep him these *hard times*.” “You should keep a *mare*,” rejoined Foster, according to Horace—

“*Æquum memento rebus in arduis  
Servare.*”

INVETERATE SMOKERS.—Both Oxford and Cambridge have been famous for inveterate smokers.—Amongst them was the learned Dr. Isaac Barrow, who said “it helped his thinking.” His illustrious pupil, Newton, was scarcely less addicted to the “Indian weed,” and every one has heard of his *hapless courtship*, when, in a moment of forgetfulness, he popped the lady's finger into his burning pipe, instead of *popping the question*, and was so chagrined, that he never could be persuaded to press the matter further: Dr. Parr was allowed his pipe when he dined with the *first gentleman in Europe*, George the Fourth, and when refused the same indulgence by a lady at whose house he was staying, he told her, “she was the greatest *tobacco-stopper* he had ever met with.” The celebrated Dr. Farmer, of *black-letter* memory, preferred the comforts of the parlor of Emmanuel College, of which he was master, and a “*yard of clay*,” (there were no *hookahs* in his day,) to a bishopric, which dignity he twice refused, when offered to him by Mr. Ritt. Another learned

LOVER OF TOBACCO,

And eke of wit, mirth, puns, and pleasantry, was the famous Dr. Aldrich, Dean of Christ Church, Oxford, the never-to-be-forgotten composer of the good old catch—

“Hark, the merry Christ-Church bells,”

and of another to be sung by four men smoking their pipes, which is not more difficult to sing than diverting to hear. His pipe was his breakfast, dinner, and supper, and a student of Christ Church, at 10 o'clock one night, finding it difficult to persuade a “freshman” of the fact, laid him

A WAGER,

that the Dean was at that instant smoking. Away he hurried to the deanery to decide the controversy, and on gaining admission, apologised for his intrusion by relating the occasion of it. “Well,” replied the Dean, in perfect good humour, with his pipe in his hand, “you see you have lost your wager: for I am not smoking, but filling my pipe.”

AN EPIGRAM ON A PETIT-MAITRE PHYSICIAN.

When Pennington for female ills indites,  
Studying alone not what, but how he writes,  
The ladies, as his graceful form they scan,  
Cry, with ill-omen'd rapture, “*killing man!*”

Dr. Parr like the great moralist, Johnson, he had an aversion to punning, saying, it exposed the poverty of a language. Yet he perpetrated the following

THREE CLASSICAL PUNS:

One day reaching a book from a shelf in his library, two others came tumbling down, including a volume of Hume, upon which fell a critical work of Lambert Bos: “See what has happened,” exclaimed the Doctor, “*procumbit humi bos*.” At another time, too strong a current of air being let

into the room where he was sitting, suffering under the effects a slight cold, "Stop! stop!" said he, "this is too much; at present I am only *par levis ventis*." When he was solicited to subscribe to Dr. Busby's translation of Lucretius, published at a high price, he declined doing so, by observing, at the proposed cost it would indeed be "Lucretius carus."

**PALEY'S SKETCH OF HIS EARLY ACADEMICAL LIFE.**—In the year 1795, during his visits to Cambridge, Dr. Paley, in the course of a conversation on the subject, gave the following account of his own academical life; and it is here given on the authority, and in the very words, of a gentleman who was present at the time, as a striking instance of the peculiar frankness with which he was in the habit of relating adventures of his youth. "I spent the two first years of my under-graduateship (said he) happily, but unprofitably. I was constantly in society where we were not immoral, but idle and rather expensive. At the commencement of my third year, however, after having left the usual party at rather a late hour in the evening, I was awakened at five in the morning by one of my companions, who stood at by bed-side and said, 'Paley, I have been thinking what a d—d fool you are. I could do nothing, probably, were I to try, and can afford the life I lead: you can do every thing, and cannot afford it. I have had no sleep during the whole night on account of these reflections, and am now come solemnly to inform you, that, if you persist in your indolence, I must renounce your society. I was so struck (continued Paley) with the visit and the visitor, that I lay in bed great part of the day and formed my plan: I ordered my bed-maker to prepare my fire every evening, in order that it might be lighted by myself; I rose at five, read during the whole of the day, except such hours as chapel and hall required, allotting each portion of time its peculiar branch of study; and, just before the closing of gates (nine o'clock) I went to a neighboring coffee-house, where I constantly regaled upon a mutton-cop and a dose of mik punch: and thus on taking my bachelor's degree, I became *senior wrangler*." He, too, filled the trust-worthy and dignified office of Tutor of his College, and deserved, though he did not die in possession of, a bichopric.

**AMERICAN TURF REGISTER AND SPORTING MAGAZINE.** Vol. VII, No. 1. Baltimore. GEORGE B. SMITH. This sporting periodical does not flag under the guidance of its new Editor. Mr. Smith. From the September No., we extract an account, by Commodore Porter, of the Arabian horse, differing in many respects from any, we remember to have seen before.

**GENUINE ARABIAN HORSE—HOW DISTINGUISHED.**—About a month since I saw a singularly beautiful light chestnut sorrel horse standing in my yard, no one was holding him, his bridle was laying over his neck, and the person having charge of him was standing behind him, plating his beautiful long silky tail, which trailed on the ground; he appeared to be full of life, spirit and intelligence, and as docile as a dog.

There was something so fascinating in the appearance of this animal, something so gazelle-like, that I was determined if he was for sale, I would have him *coute que coute*. His age I ascertained to be a little over seven years. He had come from the city of Sulimanich, in Thaurdistan, which is a province bordering on Persia on one side, and on the other side by the Pachalic of Bagdad, which latter borders on the great desert of Arabia. The horse belonged to an Agha, who had recently arrived from thence; he said the horse was a little sick, and would not eat, and that as the Agha was compelled to return immediately, he had offered the horse for a sum which no one knowing the value of a Thaurdistan horse could refuse to give. I finally closed the bargain for the horse, adding a present of two hundred and fifty piastres to the groom.—After trying the horse under the saddle, and approving of his gait and fleetness, I sent for the sultan's farrier, who the moment he saw the horse pronounced him not only a pure Arabian, but a beautiful one, and said that he had seen but one so pure before in his life.

I now sent immediately to the Agha to request him, if in his power, to give me the pedigree of the horse; he sent me word that he did not know his pedigree, nor did the person from whom he bought him—that the Kurds when they stole a horse, stole

only the best, and did not stop to inquire after the pedigree; but if I wished to satisfy myself that the horse was of the pure Arabian breed, I must examine his neck, on both sides of which I should find a beautiful natural tree projecting upwards from half way down the neck, and that I should find spurs on his fetlock joints, both of which were certain indications of the purity of his blood.

About half way down his neck, a few inches from the mane on both sides, I found a round dark spot, rather larger than a duck shot, destitute of hair, but around these, to the size of a dollar, the short and silky hair made several eccentric turns, then shot up towards the ears in the form of an ostrich plume; nothing can be more beautiful, a spur of two inches long, of the size of the little finger, at the root, gradually tapering to a point, and turning up like those of a cock. On the hind fetlocks were the same, but not more than half the length—all were slightly fringed about the root with soft silky hair.

On being satisfied of the value of this horse, which circumstances had placed in my possession, I told the doctor to go to work and cure him if possible. He felt the pulse of his legs, then examined his mouth, and felt his ears, and turning to me, said, he had the *guanz kemick*, which when translated means the eye bone, or bone eye. Never having heard of such a disease, I asked him what it was; he thrust his finger into the lower part of the horse's eye, and turning the lower lid wrong-side out desired me to feel of it. I did so, and felt a hard bony substance; the lid was much inflamed. He now thrust a needle with horse hair through the black rim of the inner lid, and pulling it out of the eye, cut therefrom the bony substance. The eye bled perhaps a half spoonful; he performed the same operation on the other eye, after which he blew up each nostril through a short reed, about a spoonful of burnt alum and black pepper, which brought on a violent sneezing. He then directed that some garlic, vinegar and salt should be mixed with a kind of red earth, which had the appearance of red ochre, and that his mouth should be washed with it three or four times a day, for four or five days; he next scarified his mouth and put him into the stable. We have followed his directions, and the horse, that for a long time past would not touch barley, now eats it freely, and is to all appearance well.

This disease and mode of treatment is to me altogether new—it may not be so to others. From the inquiries I have made I am satisfied that in ten days more the horse would have been ruined—the farrier said he would have been in five. The disease, it is said, is brought on by straining their eyes in anxious waiting for their food. A Turkish horse is double haltered to both ends of his trough, so that he cannot turn his head, which of course brings a great strain on the eye when he wants to look on one side or other.

I have measured this horse from the shoulder to the ground—he is exactly four feet, nine and a half inches, (fourteen hands, one and a half inches high.) Those who know Eclipses, say that this horse is a highly flattering likeness of him. I shall keep the horse, although I have been strongly advised to send him to America, but I am apprehensive it might turn out like many, nay, I may say all such speculations. But if you know of any one who wishes this horse, they may write to any disinterested person in this country to examine and report on him, and then we will agree on the terms.

I am satisfied there is not another Arabian in Constantinople; the sultan's horses are generally spotted, very fat, and very spirited; they look extremely well with their tappings on; but I am assured that he has not a pure Arabian among them.

**THE REPUBLIC OF LETTERS; vol. III.** edited by Mrs. A. H. Nicholas; New York, GEO. DEARBORN.—Here is another admirable volume of miscellaneous reading, made up of the weekly numbers of the Republic of Letters. The contents of this, are the conclusion of *Elia*, lives of eminent British Statesmen, the well remembered *Simple story*, by Mrs. Inchbald, and the *Bee*, a collection of Essays, by Goldsmith. We have only to renew our warmest commendation of this publication, and of the taste and discrimination with which it is edited.

ORNEY'S PENTOGRAPHIC MACHINE has just

turned out another gem—a profile medallion likeness on a large scale of Chief Justice MARSHALL. The medallion from which the engraving is executed, was modelled by Launitz after the bust by Frazee, and the Pentograph has done ample justice to the model. It is a capital performance.

#### FOREIGN INTELLIGENCE.

**MASSACRE AT PARA.**—We cannot give place to the account of the horrid massacres and devastations, at the above place, without expressing both surprise and indignation, that this Government, though again and again warned of the unsettled state of things among the natives, and of their hostility to the whites—should not have sent, and kept there, or in the vicinity, some one of our ships of war. For want of such protection, the American Consul, and other Americans have lost their property, and been obliged to flee for their lives, with just the clothes they stood in. The English and the Portuguese had ships of war there, and they afforded to their countrymen, a refuge, both for their persons and property. Our trade with Para, which exceeds that, we believe, of any other nation, and the lives of our citizens, were not thought worthy of similar protection. The result will be read, in the annexed details:

**REVOLUTION AT PARA, AND MASSACRE OF THE INHABITANTS.**—We learn from Capt. Tuttle, from Para, arrived yesterday afternoon, that the Tapulians, (Natives) made an attack on Para on the night of the 14th of August, succeeded in taking it on the 23d, and made a general massacre of all the white inhabitants they could get at, the majority of which had taken boats on the first alarm. The American Consul got on board of the brig Mercator, which sailed 7 days before for this city, having lost all his effects, and happy to escape with his life. The brig was compelled to leave all her papers. Com. Morris of the Brazilian Navy, having in command 2 frigates, 2 corvettes, 1 brig, and 1 schooner of war, together with a Portuguese vessel of war and one English men of war, assisted the President in repelling the Natives, but without success, and dropped down to Cape Antonia on the 24th, having on board 3000 inhabitants who had escaped.

Landing the females and children at the Island of Mirago under the care of a guard, the men he had organized for the purpose of re-taking the place if possible. Com. Taylor had declared the city of Para under blockade. The brig Mercator, with the American Consul, C. J. Smith Esq. passenger on board, has arrived since we received the account of the Revolution at Para by Capt. Tuttle. We learn from her the following additional particulars. The President having taken no precautionary measures against this attack, which was daily expected, and of which he had been repeatedly advised both by deserters and by letters, by the Chief of the Rebels, (Antonio Vinagre) who had threatened to fall upon the city, unless his brother, Pedro, who was then a prisoner on board the Mexican ships of war, was released. The foreigners and native residents had confided in the strength and wisdom of the Provincial Government, and of the efficiency of the Marine Department for protection, that they postponed embarking until absolutely surrounded by the natives, not allowing themselves time to save their clothing or valuable effects, and some not even a shift of clothing. Our countryman, Mr. Upton, had barely time to flee on board, leaving his books in his Counting house, which were thrown into the street and destroyed.

The Indians were seen firing from the windows of the American Consul's house at the English marines stationed at Mr. Campbell's opposite, and the U. S. flag was torn up.

It was supposed the slaughter must have been immense as the motto of the Indians has been "extermination of the whites," and a more complete sack of any city probably never took place, than in this instance.

The brigs Malta and George were bound for Maranhon full of passengers. The Br. sloop of war Race Horse, with all the English merchants on board was bound for the same place in a few days.

The Indians had about 150 to 200 armed men.—The President had 300 men under him, ready for service, and several pieces of artillery which were left unspiked, and were fired from by the natives, at the whites in their retreat. The British and Portuguese vessels of war, each landed from 90 to 100 men to assist the authorities, but seeing their pusillanimity, they embarked again for their vessels.

NINE DAYS LATER FROM EUROPE.

ENGLAND.

[From the Morning Chronicle of the 19th.]

The Lords made great strides last night in the further demolition of the Municipal Reform Bill, all the clauses of which (with the exception of those postponed and the schedules) have gone through the Committee. When the Bill as amended is printed, it will hardly have one feature in common with that sent up from the Commons. In an early part of the evening Lord Melbourne declared that "so much had been done to render the bill inefficient, that he would not make any strenuous opposition to the amendment then under discussion (for continuing the present justices of peace in boroughs,) nor would he to any amendment that might hereafter be made, seeing that it was almost useless.—But when these amendments were adopted, it would then become a matter for serious consideration, whether, in the circumstances, it would be well to go on farther with the measure."

We will not fatigue our readers by a minute notice of the various alterations made last night. It would be a libel on the Commons to suppose that they will sanction alterations which have completely changed the character of the measure. The Lords have been feeling the pulse of the nation and of the Commons. They have, as usual, been laboring under a strange infatuation with regard to the indifference of the country to good government. Indeed, what can be expected from men who have no fellowship with the people, and are the dupes of every silly tale that is told them by their creatures. For instance, what could be more silly than the statement of the Earl of Galloway last night, that Mr. Douglas, lately a candidate for the representation of Glasgow, had made seditious speeches with the red cap of liberty on his head? Mr. Douglas was suddenly called on to speak from an inn window at a small town in the south of Scotland in the month of January, and he happened to have his travelling cap on. No man, but one ignorant and utterly unacquainted with the character and habits of the people of Scotland would have swallowed such an absurdity. Lord Galloway may be taken for a sample of his order. But the Lords will soon be undeceived. However, we will not anticipate the proceedings of the eventful days on which we are about to enter. We leave the Lords to the Representatives of the empire in full confidence that they and the ministers will do their duty.

LONDON, August, 21, 1835.—The Municipal Corporation Bill can no longer be said to be the measure which passed the House of Commons; and that the house will not of course acknowledge it. The Report is to be brought up on Tuesday next, when Lord Melbourne will no doubt state the intentions of Ministers with regard to the further progress of the measure.

Nothing is more striking than the change in the language adopted at public meetings with regard to the Peers which has taken place within a year or two. The Tory Lords have completely succeeded in impressing the people with the belief that till a reform takes place in the Lords, no benefit will be derived from the reform of the Commons.

MONEY MARKET.—London, August 22.—The improvement in the English Funds, which became manifest after the notice at the bank exhibited yesterday, of the intention to make advances upon stock, was continued this morning, and Consols, both for money and account, were done at 90, and omnium at 3 premium; towards the close of the day, however, they recurred to the last prices of yesterday, and left off, the former at 80 3/4 to 7 1/8 the latter at 2 3/4 to 7 1/8. Exchequer Bills and India Bonds have suffered no change; Bank Stock and India Stock have each advanced 1-8 per cent.

For a time the foreign market evinced a tendency to improvement; Portuguese Bonds were done at 89 3/4 and 56 3/4; Spanish Cortes Bonds at 43 3/4, and Scrip at a discount of 15 3/4; but this amelioration was not permanent, they all declined rapidly in the latter part of the day, and the final

quotations, as compared with those of yesterday, showed a depreciation in Portuguese Bonds of 1-2 per cent, in Spanish Cortes Bonds and Scrip of 1 1-2 per cent, and in Passive and Deferred Stock of 3-4 per cent.

FRANCE.

Our usual express has brought us the Paris papers of 20th. The Chamber continued on Wednesday to be occupied with the new laws on the press and the jury, but we have not room for the debate.

An amendment was proposed by M. Teste, to the effect that when a condemnation should be pronounced only by a simple majority, the capital punishment it might involve should be converted into perpetual imprisonment, or the galleys for life.—This amendment was rejected.

The Secret Vote next occupied the Chamber.—As the jury are allowed to deliberate among themselves, it is thought that real secrecy cannot be obtained. On the question of transportation being discussed, M. O'Dillon Barrot described with great eloquence the cruelty and injustice of combining the two punishments of incarceration and banishment, which the law had hitherto always separated. This brought up M. Duchatel, who pointing significantly towards the Opposition, said that the proof of the efficacy of this punishment was, that it was capable of frightening the enemies of the Government. At this outrageous allusion a part of the Chamber rose en masse, a deafening tumult ensued, and M. Duchatel was obliged to explain his expressions.

Fieschi, it is said, has solicited Mons. Claux d'Est Ange, one of the most celebrated barristers of France, to undertake his defence.

We received, at a late hour this morning, the Paris papers of Tuesday. They bring us an account of the first debate on the New Jury Law. Some amendments were proposed. Monsieur Hebert wished that the Court of Assizes should, as in 1831, be called upon to decide between the majority and the minority of the jury, when the majority should not exceed seven. M. Jolivet proposed that that court should be empowered to annul the sentence of the jury—in cases only of condemnation—when it should appear unjust; in which event the cause should be referred to another session of assizes. M. Vatout said that he shrank from the thought that one single man might henceforth send a man to the scaffold. During the discussion the centres kept a continual buzz, which made the debates almost inaudible. The Ministerial orators were hardly applauded; the Opposition speakers could scarcely get a hearing at all. The amendment of M. Hebert may probably be carried, for the question will then be readily abandoned to the judges, and the court will virtually pronounce the verdict. The amendment of M. Jolivet has no chance of being adopted.

The Court of Peers yesterday pronounced sentence on 24 of the prisoners of April, declared to be contumacious. Three of these were acquitted; one condemned to transportation; and the rest to various periods of imprisonment, varying from 10 to 20 years.

BOURSE.—Paris, Thursday, August 20.—Half past Three.—The market has been again depressed, with, at times, somewhat more business than yesterday. For Money, the Five per Cents. have declined 30c., and the Three per Cents. 15c. For the Account, the depression has been a shade more in the Three per Cents.—opened at 78f. 85c., they rapidly went down to 78f. 79c., and fluctuated 5c. for some time, and then giving way, they closed at 78f. 60c.; at one period the money price was higher than for the account, viz. 78f. 70c. against 78f. 65c.

The continuation of accounts of the risings in Spain, demanding of the Government more energetic measures against the Carlists, has tended to further lower the Spanish Securities.

SPAIN.

The following extract from the Journal du Commerce of Valencia, of the 7th instant, gives further details of the late disturbances in that city. "On Wednesday evening the report spread that the factions had entered Villa Real, and committed unheard-of atrocities on the Urban Militia of that city.—Nothing could exceed the pride and insolence of the Carlists. They outraged the Liberals in every manner they could think of. The patience of the inhabitants of Valencia was at last exhausted. The Urban Militia were called to arms. It was easy to see that the object of this was to chastise the Carlists, who, taking advantage of a scanda-

lous impunity, would have proceeded to still greater excesses. There were then in the prisons a multitude of prisoners whose crimes demanded prompt punishment. That this should be inflicted the Urban Militia demanded in a manner at the same time respectful and energetic. The Commandant, the Count D' Almodovar, promised to take this demand into consideration, and also to adopt other popular measures, such as the dismissal of suspected servants of the Government, and the suppression of convents. For the greater security, the Militia took upon itself the responsibility of guarding the prisoners from the prisons of Cuarte, Serranos, St. Narcossa, and the ecclesiastical places of captivity. They were accordingly conducted, to the number of more than one hundred, to the guard-house of the market place. The judicial authorities expeditiously tried the most criminal, and at four o'clock Portambec, Palmerolas, the Canon Astolosa, Father P. Lopez, two of the assassins of Paniagua, and another well known for his crimes, were shot in the square of the old custom-house. The others were conducted to Grao, to be embarked and transported to Centa. The last words of Portambec, uttered with a loud voice, at the very moment of his execution, were—'Vive Charles V!'—Death to the factious.' Two of the prisoners, declared innocent, were restored to their families."

Letters from Madrid, dated the 14th inst., say that disturbances similar to those at Barcelona, Saragossa, and Valencia, had broken out at Cadix, but had immediately been suppressed by the firmness of the authorities of that town.

The Madrid Gazette, of the 10th, says that an extraordinary courier had been despatched to Lisbon in order to hasten the entry of the Portuguese auxiliaries into Spain.

The Journal de Paris has the following:—"Don Carlos marched on the 15th towards Vittoria.—Cordova who is at Logrono, observes all his movements. Three battalions of Carlists arrived on the 12th inst. at Aoyz. Their intention seems to be to enter Arragon; but Iriarte, who arrived the same day from Pampeluna with his division, and Guerrea, who is at Arzajona also with a force, are in readiness to prevent this movement. The same journal informs us of an arrangement for the pacification of Spain, attributed to Las Amarillas, and which it is said the Queen and Count Toreno have approved of. This project is to be laid by France before the Congress of Toplitz, to receive the concurrence of the sovereigns of the north, and their intervention, which its execution will make necessary. The following are the terms to be proposed:—1st. Isabella II. is to marry the eldest son of Charles V. 2. Don Carlos is to abdicate in favor of his eldest son. 3. This abdication will cause the law of exclusion against Don Carlos and his family to be annulled. 4. The three sons of Don Carlos are immediately to enter Spain, escorted by 25,000 French, and a single regiment of English. The eldest son is to take the name of Louis II., and will be proclaimed King of Spain conjointly with his consort. 5. All the powers of Europe are to recognize his Government. 6. A pension of five millions of reals is to be granted to Don Carlos. 7. The Queen is to have three millions of reals, but must live at fifty leagues distance from the Court. 8. The Estatuo is to be maintained. 9. The privileges of the Basque provinces and of Navarre are to be preserved and guaranteed by France and England. 10. An amnesty for all political offences to be proclaimed. 11. A general liquidation of debts contracted at all periods, even the loans raised by Don Carlos included, to take place. 12. All special measures respecting the army and administration are to be adopted immediately by Louis II. 13. English and French troops are to remain in Spain as long as Louis II may judge it necessary. 14. The Cortes are to be assembled as soon as the Government shall think fit, in order to recognize the new Government, and take the oath of allegiance.

"Bilboa," adds the same correspondence, "is observed as far as Portuguese, by the Carlist troops under the orders of Sarozza; and St. Sebastian by the division of Miguel Gomez, who has his head quarters at Urnista." There is a report which has been taken up by one of the French papers that the republic has been proclaimed at Saragosa; that all the authorities have been expelled from the town, and that the whole surrounding country has submitted to the government of a republican junta.

The Indicateur de Bordeaux of the 15th does not confirm the intelligence it contained the preceding day, of the rising of the four provinces, Catalo-

nia, Arragon, Valencia, and Murcia, with the declaration of their independence of the Queen's Government. The Republic has not, it says, been proclaimed, but representations have been addressed to the Queen to demand a more liberal administration. A conspiracy, says the *Phare de Bayonne*, has been discovered at Carthage. Its object was to proclaim Don Carlos, and assassinate the Liberals. A letter from the Aid-de-camp of Don Leon Iriarte asserts that the loss of the Carlists in the engagement at the Bridge of Sanguessa on the 6th instant amounted to 80 killed, 100 wounded, and 12 prisoners.

The *Journal de Paris* informs us that General Coluby, Governor of Tarragona, has taken refuge in France, in consequence of disorders, similar to those at Barcelona, having broken out in his government.

The following is an official account of the disorders which took place at Valencia on the 6th inst. It is dated August 7th:—"The people of Valencia—excited by the momentary advantage which a band of factious men, commanded by Quillet and Serrader, had gained over a column of 500 men, who were in pursuit of them—rushed in a mass to the prisons occupied by some persons detained there for political offences, and having, with the help of the Urban militia, got them out, conducted them to the central guard house, and demanded that the Military Commission should summarily judge their cause. The Captain General immediately hurried to the spot to appease the tumult, but he was not listened to, and the disorder continued to increase, in spite of the efforts of the authorities and the presence of 300 artillerymen. The Captain-General then assembled the battalions of the militia, although they were not complete, many of the privates of that service being among the anarchists, and those who were present to act against their comrades, if the justice demanded, were not promptly accorded.—The tumult went on increasing, and the country people flocked together to enter the city, and take part in it. In the midst of this conflict, the military commission, some chiefs of the militia, and other influential persons, met together at the house of the Captain General; and after vain attempts to appease the people, and to gain over the militia, determined to try at once three individuals accused of a crime which is subject to a sentence of death. This resolution was not deemed sufficient by the mob. The anarchists insisted that four others also should be tried at the same time. They threatened to kill the prisoners, who were very numerous, if their demand was not granted. This menace, which might have been put into execution without hindrance, decided the fate of the seven prisoners; they were shot, and the others transferred to another prison. The Urban militia then submitted to the authorities, and order was re-established.

Private letters from Bayonne inform us that Don Carlos had arrived on the 10th of August at Puenta Larra, with six battalions and four squadrons of lancers, and was expected to be joined by three additional squadrons. These forces passed the Ebro on the morning of the 10th, for the purpose of attacking the Christians under the orders of Bedoya, in the environs of Pancorbo. The movements of the Carlists towards Castile are watched narrowly by Cordova, who is in march with his whole force towards Haro. The Brigadier General Giurque, four battalions of Navarrese, three of Castilians, two strong guerillas, and a squadron of lancers, were operating to enter into Arragon.

Another insurrection (says the same correspondence) broke out at Saragossa on the 10th. The news arrived at Bayonne by express, on the evening of the 14th. The Governor is reported to have been assassinated; the troops expelled from the town; the Constitution of 1812 proclaimed; and popular authorities substituted for those of the Queen.

LATER FROM EUROPE.—The *Napoleon*, packet from Liverpool of the 24th ult., furnishes us London dates to the 23d, and Paris of the 20th.

In England the municipal corporation bill absorbed all interest. It had been so modified by the House of Lords, where it was still under discussion, that it is no longer the same bill, and it is confidently said the Commons will not accept such a mutilated thing. Great excitement prevailed in the kingdom, and of course, against the Lords, who are supposed to be thwarting the popular branch.

In France the *gag-laws*—outrageous any where, and especially outrageous in a country with a written charter, guaranteeing the liberty of the press—were under discussion in the Chamber of Deputies. All material amendments are repelled, and there seems little reason to doubt, that the bills will pass as proposed by ministers.

The affairs of Spain seem no nearer any peaceful issue. The forces of Carlos do not quail before those of the Queen, augmented though they be, by foreign auxiliaries.

[From the *Atlas*.]

#### THE TWO DEAF GENTLEMEN.

TRANSLATED FROM THE FRENCH.

"Sir, your dinner is served up!"

"Well—but I do not wish to dine alone—can't you find some other traveller in the hotel?"

"We have only one—and I will invite him if you wish; but I forewarn you that he is as deaf as an adder."

"No matter, I will halloo."

And the boy who had improvised this piece of pleasantry—which the reader will, according to his taste, think either good or bad—went to invite the traveller. "A stranger," said he, "desires to have your company at dinner, but I consider it my duty to inform you that he is so deaf that he wouldn't hear thunder strike at his side."

"No matter, I will halloo."

The two gentlemen greeted each other with a silent bow, took their places and commenced an insignificant conversation on the rain and the fine weather, upon the object of their travels, and other common matters. The first speaker began by singing out pretty loud; the other answered in a still louder tone; the reply waxed louder, like the ascension of the gamut, and so the rejoinder, always *crescendo*.

I have seen in the course of my sea-voyage, two unfortunate young men, guilty of some petty larceny, on whom their superiors inflicted a novel punishment. They had been condemned to whip each other reciprocally, first one striking and then the other, a blow with the cat-o'-nine-tails. The one who began struck only a light blow; his comrade felt it however, and struck in his turn, still feebly, but with a little more force. The third lick was laid on without hesitation, the fourth with a spirit of vengeance, the fifth with fury, and the two little unfortunate devils, ended by beating one another as hard as they could lay it on, crying as loud as they could bellow.

So did our travellers; at each reply the voice increasing in tone, they began at last to yell with open mouths, and would have used speaking trumpets could they have had them at their command.

One of them at last said:

"Sir, were you deaf born or by accident?"

"What do you call deaf? Deaf yourself, and with a witness."

"Ah! good heavens! you are so very deaf that our conversation will destroy my voice for six weeks, at least."

"Poor man, you believe that all the world is afflicted with your infirmity."

"Ah, Sir! I pity you sincerely; but do not insult me by trying to throw a bundle on me, of which I cannot relieve you."

The boy perceived that the conversation was about taking a serious turn. He spoke some words in a low voice which both the deaf gentlemen heard wonderfully well—and which let them into the secret. They had the good sense to laugh at the joke—but some difficulty, during the remainder of the dinner, to descend to an ordinary diapason, after the vocal efforts they had made.

[From the *National Gazette*.]

LAMARTINE'S PILGRIMAGE.—M. de Lamartine, the French poet, has won all suffrages by his *Pilgrimage to the Holy Land*, of which four European editions have already appeared. The author before he left Paris, had prepared his readers for the kind of work they were all to expect on his return from that glorious country, to which his thoughts had so often wandered. "I go," were his words, "to seek for individual inspiration on that great theatre of the religious and political events of the ancient world. I think not of writing; but I go to read, before I die, some of the brightest pages of the book of nature. And if poetry shall find there

any images, or new and fruitful themes of inspiration, I shall content myself with treasuring them in the silence of my bosom, to color the brief literary future which may be in store for me." Probably no work in the French language contains a passage of greater ardor, or nobler eloquence, or deeper sensibility. The pilgrim carries the reader along with him through all his wanderings in the land of miracles, where the burning sun, the rushing eagle, the barren fig tree—all the poetry and all the pictures of the bible are visible; where, in his passionate words, "every name unfolds a mystery, every cave speaks of the future, every hill responds with the warning of a prophet; where the dried-up torrents, the cleaved rocks, the open graves, attest the supreme power of the deity, and the wilderness itself seems dumb with terror, as though afraid of breaking the silence which hangs over it since the voice of the Almighty first resounded within its borders" Chateaubriand, if not eclipsed, has at least found a rival in this new poet-traveller, whose work is justly regarded as one of the most remarkable, valuable and curious.

We learn that it is now partly in type in this country and will be issued immediately in Waldie's Select Circulating Library, a vehicle which, from the great extent of its subscription, is calculated to afford gratification in the perusal which a mere small book edition could not give. The work is an expensive one in Europe, but we suppose will be reduced on the Waldie principle to a moiety of a dollar.

NAVAL.—The U. S. schooner *Grampus*, Captain Ritchie, arrived at Pensacola, on the 27th ult. The *Grampus* sailed on the 8th August, bound to Matamoros, Galveston, &c. in Mexico, and when in lat. 27 22, long. 94 40, experienced one of the hurricanes which are so common in the Gulf of Mexico at this season; it lasted 48 hours, during which time the *Grampus* sustained much damage—the hammock nettings stove in, main jib boom carried away, sails and rigging much injured, and the officers and crew suffered considerably. On the 19th inst. discovered a wrecked sail to windward. The Captain stood for the wreck, which proved to be the schr. *Watchman*, Capt. Murray, four days from Rio Grande, bound to New Orleans, with \$100,000 on board, many passengers, among whom were the ex-vice President and family of Mexico. Capt. Murray of the *Watchman* made his distressed situation (as the *W.* was dismantled and without masts, sails, boats, &c.) known to the commander of the *Grampus*, who furnished him with spars, sail, &c., and safely landed him at the S. W. Pass of the Mississippi river on the night of the 25th.

[From the *New Haven Herald of Wednesday*.]

The steamboat *Boston*, from New York for Providence, was run into by a schooner under full sail, and showing no lights, on Monday night, and was so much damaged as to be obliged to put into Huntington har' for repairs. She sailed again and arrived at Providence next day. The imprudence of vessels running in the sound at night without hoisting a light, is so apparent, that it cannot be justified. Penal enactments should oblige every shipmaster under sail to give fair warning of his position and approach.

From Charleston, by the *Steamboat*, we have papers of Saturday evening.

The annexed is the only item of interest:

CHARLESTON, Saturday Afternoon.—*Effects of the Gale*.—A gale of wind commenced on Tuesday last from N. E. to E. which continued from that quarter until yesterday noon, when it suddenly shifted to S. E. thence to S. S. E., and blew with great violence. Little or no damage was done to the shipping, owing to the greatest violence of the gale being from S. The Spanish brig *Isabella* the 2d, lying for several days in the stream opposite Magwood's wharf, was driven into Fraser & Co's wharf, after parting her cable and dragging her anchors, destroying her boat, and losing one man overboard, in what manner is not known. The packet ship *Saluda* was driven high up the dock at Boyce & Co's wharf, where she is aground.—The sloop *Martha* and *Jane*, lying at Williams's wharf, had her larboard side stove in and sunk. A wood schooner was also sunk at Mey's wharf. A schooner called the *Farmer*, lying in Ashley River, was driven ashore on the east side, a little above the bridge, where she is aground. The Steam Packet *Edwan* lost her figure head and a few stunchions. The South pier of Chiniquet's wharf received com-

siderable damage, also a small pier at Vanderhorst's wharf. Gibbs's wharf is likewise badly injured, and some damage has been sustained at Williams's wharf, the south side of which is gone. Gadsden's North wharf has received considerable damage, the head being swept entirely away, as has also Norton & Carroll's wharf.

The Bathing House on East Bay, which has stood sixteen years, is so much injured as to be beyond repair.

We have heard of no injury in the city, with the exception of some fences and trees blown down.

We learn from several persons who visited Sullivan's Island this morning that no damage whatever was sustained there. The tide did not rise higher than an ordinary Spring tide.

Much damage has no doubt been done to the Rice and Cotton Crops, at points exposed to the influence of the gale.—[Southern Patriot.]

**SHIPWRECK.**—Captain Norris, of the brig *Cross*, der, from Neuvitas, informs us that when coming down the river, he was boarded by Capt. Hoskins, of the schooner *Sophia*, 2 Eliza, of Hartford, 17 days from Edenton, for Kingston, Ja., with stores, &c. who stated that his vessel was totally lost on the 10th ult. at half-past twelve at night, about 6 miles east of Neuvitas Bay, having mistaken the land for St. Domingo, in consequence of passing the Leeward Islands without seeing the land while lying in a hurricane on the 15th. The crew, with Dr. M. E. Sawyer, of Edenton, a passenger, all saved. The natives began plundering the vessel, and the captain was going in a government boat to take off the crew, and save what part of the cargo he could.

**FROM ANTIGUA.**—The Wilmington People's Press has received Antigua papers to the 18th ult. The hurricane of the 15th was terrific in that island. It began at 4 o'clock, P. M. and continued till midnight. When it was passed, "the town presented a painful scene of wreck and ruin, in a wide wasting havoc and a confused intermixture of fragments of houses, trees, inclosures, &c. Accounts from the country state that buildings, sugar works, and fields of the plantations, present an equally frightful picture. The loss is estimated at nearly half a million of dollars. 20 schooners and 2 bergs were driven on shore. Several blacks were killed on the plantations, by the falling in of the houses, &c."—[Jour. of Com.]

**OUTRAGE AT STATE PRISON.**—On Saturday last, after dinner, Harvey Griswold, a convict, became disobedient, and refused to leave his cell with the other prisoners, to go to his work. Information of his conduct having been conveyed to Capt. Pillsbury, the Warden, he, with Mr. Coolidge, the assistant warden, repaired to his cell, to ascertain the cause. After a little conversation, Griswold told them he did not feel disposed to work, and that he should not leave his cell; Capt. Pillsbury stepped in, and took him by the collar, when a scuffle ensued, during which Griswold drew a knife he had concealed in his coat sleeve, and struck at Capt. P.'s head or throat; the blade entered the Captain's left shoulder partly on the back, to the depth of one and a half or two inches, and about four inches long. Mr. Coolidge in the meantime seized him, and soon received a dangerous cut on the wrist, which bled so profusely that he was compelled to go immediately to the Hospital for aid. In the meantime, Capt. Pillsbury was engaged unarmed, with the assassin, and received another severe wound from his knife in the thigh. What appears very remarkable is, that Capt. P., although he felt something like a shock of electricity, when Griswold struck the first blow, did not know that he was wounded until he had forced Griswold half way to his work. Feeling the blood trickle down his back, and discovering his wound in his thigh, the convict was immediately remanded to his cell, where he will remain until the next session of Court, to be tried for the offence.

We are pleased to learn, that although both officers were severely wounded, they are considered out of danger.—[Hartford Times.]

**MURDER CASE.**—A black man was killed in the Swamp, on Sunday night. The act was perpetrated by a white woman, in a negro hotel. She alleges it was to protect herself from the most offensive violence, to which her character, most probably, induced the attempt. The circumstances of the case, favor this conclusion.—[She is in prison for trial.—[Cincinnati Gazette.]

[From the Cleveland Gazette.]

**REMARKABLE CASE.**—Mr. John T. of

Springborough, Warren county, Ohio, has been absent from his family for about two weeks. His absence was to them wholly inexplicable and excited great apprehension. On Sunday, Sept. 13, he came to this city on his return home, and gave the following account of his absence.

He came to Cincinnati, Saturday, August 23, where he transacted some business and received a small sum of money. On Sunday morning, Aug. 30, after breakfast, he set out for home, on horseback. On the hill road to Carthage, between four and five miles from Cincinnati, at a convenient place for instantly securing him, he was suddenly dragged from his horse by two footmen whom he had just passed. His horse was turned loose, and himself blindfolded, and silence enforced by threats of instant death. His money, about 150 dollars, was taken from him, with inquiries indicating that a mistake had been made in the person seized and in the amount of his money. He was detained all day blindfolded, and at night conducted, in the same condition, to the river, where he was put on board a boat, so fitted that he was confined in an apartment where he could make no observation of what was passing around him. In this way he was carried down the Ohio river to a point below the Yellow Banks, where, on Wednesday night, September 10, he was taken up a high bluff to a distance from the river, and set at liberty. He came to Cincinnati on his return, as stated, and was accompanied to the scene of the robbery by some friends. Upon inquiry, his horse, saddle and bridle were recovered, having been taken up almost directly after his capture. Mr. Trotter is represented to be a respectable man, worthy of belief. The solution of his story would seem to be this: that arrangements had been made to rob and kidnap some person, and after seizing him, the alternative was to murder him or to proceed. He was captured and blindfolded so suddenly, that he has no distinct knowledge of the physiognomy of the persons that seized him.

**THE REGATTA.**—A more beautiful afternoon never graced a public exhibition than that of Monday last. Our glorious bay was studded with boats—some steaming, some sailing, and some rowing—the battery, in its whole length—the neighboring wharves—and the Castle of the garden—were alive with spectators, anxious to witness the friendly rivalry of the Amateur Clubs. The result is well told by the Gazette, the respectable senior Editor of which, awarded the prizes.

The boats took their places on starting in the order previously arranged, and, according to the report of the judges, arrived as follows:

1. Wave—time 34 minutes.
2. Eagle—time not noted.
3. Dolphin, do.
4. Neptune, do.
5. Wakona, do. (4 oars)
6. Atlantic, do.
7. Jersey, do. (4 oars)

The distance performed was 5 1-2 miles.

Four splendid silver pitchers were then presented to the members of the successful clubs by the judges, the senior of whom prefaced his remarks with the following address.

**My young friends.**—By your kindness and politeness I have been appointed one of the Judges of this afternoon's exhibition, the first of the kind ever presented to an American public, for which I beg leave to thank you. To you, gentlemen, belongs the credit of giving origin to such manly exercises, which tends to promote health, strength and longevity. If it be said that you are imitating the Lords and gentlemen of England in their Regattas, the most fastidious moralist cannot complain, while you devote no hours for rational exercise but those on which your various occupations have no claim.

—Your early rising, and a tug at the oar, give a zest to your daily business, and prepare you for the acquisition of the evening, accomplished by your mothers, sisters, and sweet-hearts, the witnessing of which has often almost induced me to wish that I

Proud as I feel on this occasion to perform the most gratifying part to gentlemen of the *Wave*, I am sending you a PRIZE composed of precious metals, as a small tri-umphant superiority. In doing and it must be equally gratifying to find among your young men, that not one comes in ex-

pression of countenance that is not in unison with your own.

You have, gentlemen, this day set a noble example to the young men of this great and growing city—and while you continue to set within the rules of strict propriety, your Regattas will not only not be opposed but patronized by the best members of the community.

May you live long, be prosperous and happy.

The several members of the Clubs replied in an appropriate manner, after which, with a large number of guests, they partook of a repast appropriate and splendid.

**THE ROWING MATCH** between the officers of the Pique and the Quebec Amateurs, and a second one between the seamen of that frigate and the boatmen of the Quarter-Master General's department, will come off to-morrow, at 11 o'clock in the forenoon; distances, three miles for the first, and four miles for the second, marked off before the town. The Pique's boat is a gig, named the Cat and the Fiddle, 30 feet in length, and the town gig the Water Witch, 35 feet, both four-oared.—[Quebec Gazette.]

**THE BALLOON ASCENSION.**—Wednesday afternoon, Mr. Lauriat made an ascension from Castle Garden, in the presence of many thousand spectators, not however with his daughter, as was anticipated, by reason of the deficiency of gas. They both seated themselves in the car, but before it had ascended above the railings of the Garden, it was dashed against them with much violence, and serious consequences must have followed but for the prompt assistance received at the precarious moment by those persons who were nearest them. Instead of being intimidated by this accident in the outset, the intrepid aeronaut and his fair companion still expressed a desire to persevere; when, the car being adjusted, those who held the cords, let go, but with no better success than attended the first effort, for although all the disposable ballast was instantly thrown out, there was not enough power to carry them further than the promenade on the Battery, outside of which the balloon descended, and was secured. After this second abortive attempt, it was evident to all that the balloon was not sufficiently inflated to ascend with both passengers, and the lady was induced to abandon her intended trip, which she did reluctantly, and we are happy to add, without having received serious injury.

After being thus lightened, Mr. Lauriat ascended, amidst the cheers and plaudits of the spectators. The balloon passed over the eastern part of the city, in the direction of Williamsburg, Long Island.—[Mercuriale.]

We have been furnished by a friend with the following census of the Eighth Ward:—[Evening Post.]

Allowing an average estimate for families yet out of town, the population of the Eighth Ward is about 27,500. The excess of females is about 2500. The rate of the Eighth Ward, for the last few years, has been about one tenth of the whole city rate; it is therefore reasonable to suppose the population to be in the same ratio, which will make the inhabitants of this city amount to at least 275,000. In 1830, the 8th ward contained 30,729 people, and the city 203,000.

**SHIP CANAL.**—The corps of United States Engineers who for the last five months have been engaged in surveying several routes for a ship canal around the Falls of Niagara, through this county, have at length finished the work intrusted to them. The result of their labors will be submitted to Congress at an early day. In the mean time we would state, for public information, that the proposed canal is considered quite practicable, and that too, at a cost far less than the great importance of the work would warrant. We trust, therefore, that no efforts will be spared to induce Congress to order the construction of this important link in the navigation of the great lakes.—[Niagara Courier.]

**CANAL TOLLS.**—The tolls on the New York Canals for the two first weeks in Sept. amount to the sum of \$101,080 22. This exceeds the receipts for the corresponding two weeks in 1834 by the sum of \$24,750 41; and it exceeds the receipts for the same time in 1833, when the tolls on merchandise were 25 per cent higher than now, by the sum of \$14,731 21.

The whole tolls from the opening of navigation to the 14th Sept., amount to the sum of \$223,310 22; being an increase, from last year, up to the same time, of \$172,738.—[Albany Argus.]

The Commercial Agent of the United States at Antigua, writes to the Secretary of State that the Governor of that Island has opened the port for six months from the 14th August, for the importation in vessels of all nations, duty and tonnage free, of the following articles, viz:—Flour, corn, and pulse of every description; corn meal; salted, dried, and pickled fish; salted pork and beef, mill timber, and lumber of all kinds; staves, shingles, and wood hoops.

The following Poem, by Lord Bacon, is now just published for the first time, in a new life of the author:—

The world's a bubble, and the life of man  
lesse then a span.  
In his conception wretched, from the wombe,  
so to the tombe;  
Curst from the cradle, and brought vp to yeares,  
with cares and feares.  
Who then to fraille mortality shall trust,  
But limmes the water, or but writes in dust.  
Yet since with sorrow here we live opprest:  
what life is best?  
Courts are but only superficiall scholes  
to dandle fooles.  
The rurall parts are turn'd into a den  
of saunge men.  
And where's a city from all vice so free,  
But may be term'd the worst of all the three?  
Domesticke cares afflict the husband's bed,  
or paines his head.  
Those that live single take it for a curse,  
or doe things worse.  
Some would haue children, those that haue them, mone,  
or wish them gone.  
What is it then to haue or haue no wife,  
But single thraldome, or a double strife?  
Our owne affections still at home to please,  
is a disease,  
To crosse the sea to any foreine soyle  
perills and toyle.  
Warres with their noyse affright vs: when they cease,  
We're worse in peace.  
What then remains? but that we still should cry,  
Not to be borne, or being borne to dye."

**CIRCULAR.** To ENGINEERS and Superintendents of Railroads and Canals.—I am preparing to issue a new edition of my RAILROAD AND CANAL MAP; and being desirous to correct the errors of the first edition, I take the liberty to request the ENGINEER, or SUPERINTENDENT, of every Railroad and Canal in the UNITED STATES, to furnish me at his earliest convenience with a full and precise account of the condition of the railroad under his direction or charge. He is requested to state the length of the road, the number of miles completed, the elevation it surmounts, the radius of its curves, the style of its construction, its average cost per mile, the number, if any, of inclined planes, with stationary engines—in short, every thing which may be of interest to engineers, or others who may be connected with the subject of Railroads and Canals.

To such as comply with the above request, and furnish the desired information previous to the first of August next, a copy of the new edition of the Railroad and Canal Map, will be sent, by mail or otherwise, as may be directed, as soon as completed.

D. K. MINOR.

New-York, June 27, 1835.

#### RAILROAD IRON.

300 tons of Railroad Iron of the T pattern, just imported and for sale by  
HOWLAND & ASPINWALL,  
55 South street.

#### TO CONTRACTORS FOR EXCAVATION AND MASONRY.

PROPOSALS will be received at the Office of the Philadelphia and Reading Rail Road Company, in Philadelphia, on the 19th and 20th days of October next, for the Grading and Masonry, of about sixteen miles of the Rail Road between Pottsgrove and Norristown.

In this distance, a large amount of heavy work, deserving the attention of skillful and competent Contractors, is to let. The Jobs of most magnitude, are a Tunnel 600 yards long, and a Bridge across the Schuylkill, near Phoenixville.

Plans and profiles of the line, and drawings of the different constructions on it will be exhibited, and all other information in relation to it will be afforded, on application at the Engineer's Office, at Pottsgrove, for ten days previous to the letting.  
MONCURE ROBINSON, C. E.  
Philadelphia, Sept. 2, 1835.

#### RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order car wheels, chairs and knees, and every other description of castings required for railroads.

R-1y feb14

#### PARTNER WANTED.

Wanted, a partner in an extensive Printing Establishment. No one need apply who is not a thoroughbred printer, competent to superintend and direct an office in which upwards of 30 persons are employed, and able to furnish \$3000 cash capital. The best of references will be given and required. Letters, with real name, may be addressed to P. P. P., Post Office, New-York, postage paid, and they will be promptly attended to.

May-17

#### AUBURN AND SYRACUSE RAILROAD.

##### NOTICE TO CONTRACTORS.

Sealed Proposals will be received until the 15th day of October next, at noon, by the undersigned, Chief Engineer and Agent of the Auburn and Syracuse Railroad Company, for the Grading, Masonry, and Bridges on said Road. Individuals disposed to contract for the execution of the whole or any part of the work, will be furnished on application at the Office of the Company in Auburn, with blank forms of proposals, and printed specifications.

The contracts will be formed in the usual manner—a specific price being stated for each item of work, which price is to include the cost of material and labor required in rendering the work complete.

The proposals to be accompanied with the names of sureties, and where the parties are unknown to the undersigned or resident Engineers, the usual certificates of character and solvency will be required.

Individuals who have been employed on other works, must furnish satisfactory recommendations from the Engineer or Superintendents of the same. A rigid adherence to the conditions of each contract will in all cases be required.

It is desired that all the work in each section, including Grading, Culverts, and Bridges, should be embraced in the same contract, and it is requested that the proposals be made accordingly.

The plans of the different structures will be ready for examination at the Office aforesaid, by the 1st day of October next.

EDWIN P. JOHNSON,  
Chief Engineer & Agent A. & S. R. R. Company.

Auburn, Aug. 22, 1835.

#### AMES' CELEBRATED SHOVELS,

SPADES, &c.  
500 dozens Ames' back-strap and plain Shovels,  
75 do do round-pointed do  
150 do do cast steel Shovels and Spades,  
100 do do Bucket Shovels and Spades,  
150 do do Steel plated Spades,  
Together with Pick Axes, Plumb Drills, and Crow Bars,  
steel pointed, made from Salisbury refined iron. For sale  
by his Agents,

WITHERELL, AMES & CO.

8 Liberty street, New-York.

BACKUS, AMES & CO.

8 State street, Albany.

34-ytf

#### RAILROAD IRON WORK,

Of all kinds, made to order by GODWIN, CLARK & CO., Paterson, New-Jersey.

CAR WHEELS, BOXES, AXLES, and CAR SPRINGS, made and fitted complete, at short notice, and fair prices. Orders addressed to them at Paterson, N. J., or 24 Broad street, N. Y., will meet with immediate attention.  
Paterson, Aug. 19, 1835.

34-ly

#### STEPHENSON,

Builder of a superior style of Passenger Cars for Railroad,

No. 234 Elizabeth street, near Bleecker street,

New-York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation.

J35tf

#### RAILROAD CAR WHEELS AND BOXES AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS.

Also, Flange Tires turned complete.

J8 ROGERS, KETCHUM & GROSVENOR

#### PATENT RAILROAD, SHIP AND BOAT SPIKES.

The Troy Iron and Nail Factory keeps constantly for sale a very extensive assortment of Wrought Spikes and Nails, from 3 to 10 inches, manufactured by the subscriber's Patent Machinery, which after five years successful operation and now almost universal use in the United States (as well as England, where the subscriber obtained a Patent,) are found superior to any ever offered in market.

Railroad Companies may be supplied with Spikes having countersink heads suitable to the holes in iron rails, to any amount and on short notice. Almost all the Railroads now in progress in the United States are fastened with Spikes made at the above named factory—for which purpose they are found invaluable, as their adhesion is more than double any common spikes made by the hammer.

All orders directed to the Agent, Troy, N. Y., will be punctually attended to.

HENRY BURDEN, Agent.

Troy, N. Y. July, 1831.

Spikes are kept for sale, at factory prices, by I. & J. Townsend, Albany, and the principal Iron Merchants in Albany and Troy; J. I. Brower, 322 Water street, New-York; A. M. Jones, Philadelphia; T. Janviers, Baltimore; Degrand & Smith, Boston.

P. S.—Railroad Companies would do well to forward their orders as early as practicable, as the subscriber is desirous of extending the manufacturing so as to keep pace with the daily increasing demand for his Spikes.

H. BURDEN.

#### TO TUNNEL MINERS, DRILLERS, &c.

Wanted, immediately, 40 Tunnel Miners, (Coralish Miners will be preferred,) 80 Drillers, 50 Laborers, and two experienced Mine Blacksmiths, on the New York and Harlem Railroad, about five miles from the City. Liberal wages will be given, and cash payments made every fortnight. Apply at Mr. FOWLER'S, St. John's Hall, Frankfort street, New-York.

JOHN RUTTER, Contractor.

The Albany Argus, Philadelphia U. S. Gazette and Pennsylvania, will please copy this, and send their bills to the Railroad Company, 14 Wall street, New-York.

#### PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

Railroad Spikes of every description required, made at the Albany Spike Factory.

Spikes made at the above Factory are recommended to the public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to admit water.

Orders may be addressed to Messrs. ERASTUS CORNING & CO., Albany, or to THOMASTURNER, at the Factory, Troy, N. Y.

sept. 12-1y

#### RAILWAY IRON.

200 tons of 1 inch by 1 inch, Flat Bars in lengths of 14 to 15 feet, counter sunk holes, end cut at an angle of 45 degrees, with splitting plates and nails to suit.

250 do. of Edge Rails of 36 lbs. per yard, with the requisite chairs, keys and pins.

Wrought Iron Rims of 30, 33, and 36 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels.

Axles of 24, 26, 28, 30, 32, 34, and 36 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment.

A. & G. RALSTON.

9 South Front street, Philadelphia.

Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them.

d7linecwr

#### SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality warranted.

Leveling instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by

E. & G. W. BLUNT, 154 Water street,

corner of Maiden lane.

J31 6t

#### SURVEYING AND ENGINEERING INSTRUMENTS.

The subscriber manufactures all kinds of Instruments in his profession, warranted equal, if not superior, in principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Goniometer, with two Telescopes—and a Leveling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes.

WM. J. YOUNG,

Mathematical Instrument Maker,

No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested.

Baltimore, 1835.

In reply to thy inquiries respecting the instruments manufactured by thee, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish thee the following information. The whole number of Levels now in possession of the department of construction of thy make is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accident to which all instruments of the kind are liable.

I have found that thy patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a reversing telescope, in place of the vane sight, leaves the engineer scarcely anything to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,

JAMES F. STABLER, Sup't of Construction

of Baltimore and Ohio Railroad.

Philadelphia, February, 1835.

Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Germantown, February, 1835.

For a year past I have used Instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these Instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

HENRY R. CAMPBELL, Eng. Philad.

Germantown, and Norristown, Railroad

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, OCTOBER 3, 1836.

✶ We continue in this number, the Essay of Mr. STIMPSON, which was commenced in our last; and we ask for it a candid perusal—which, by the by, is more than we have been able, in consequence of ill health, to give it.

**RAILROAD AXLES.**—We have in our possession the model of a Railroad Axle, which, in our estimation, will be found an important improvement upon those now in use.

It has frequently occurred to us, that much difficulty and expense must be encountered in repairing the journals of railroad carriage, and locomotive, axles. So great is the burthen and speed to which they are subjected, under present arrangements, on our *short* roads—and these will both be increased when the business is better understood—that we apprehend serious difficulty in keeping the journals of a uniform size, and much expense in repairing them when they shall have, as they certainly must in time, become worn by constant use.

In order to repair a journal when worn, either in ridges from any hard particle which may find its way into the box, or out of round, from any inequality in the texture of the material of which the journal is made, the axle must be taken from the carriage, the wheels knocked off, and the journal overlaid, with an additional quantity of iron or steel, in order to restore it to its original size. This is no small matter—as it will require much time and labor, in addition to

which, is the risk of obtaining a journal free from flaws.

The improved axle, which has been patented by Mr. Force, of Baltimore, may be used—if made of good materials, and of sufficient strength not to *break*—to wear out many pair of wheels; or indeed, any number of years without any other repair than what may be made by the engineer, in a few minutes, on the road, without removing the axle, or the load from the car, or carriage. The improvement consists in the application of a *thin steel ferrule*, or thimble, which is made to fit close to, and to remain *fast on*, the journal—which is to be of the best wrought iron, about an *eighth* of an inch *smaller* than ordinary journals. This reduction of size, it is believed, may be submitted to without risk, as there is no wear upon it; and it will, therefore, always remain of its original size. The wear upon the journal comes upon the *thimble*, which may be renewed at any time, in a few minutes, by raising the carriage frame, so as to come at the journal, to knock off the *worn*, and to put on the *new*, thimble; which may of course be always on hand, fitted and numbered to correspond with each journal, and will not cost over one dollar each; and certainly not over 20 or 30 minutes of time to put it on; whereas, in the other case, it cannot, we should think, cost less than ten dollars, and an entire day's time to repair one axle.

We ask the opinion of practical engineers upon the subject, and desire to have all objections to it stated.

**INTERNAL IMPROVEMENT.**—At a meeting of the American Institute of the city of New York, held at Clinton Hall on Thursday, the 24th day of September, 1835, the following preamble and resolutions were unanimously adopted.

Whereas, this Institute was incorporated by the Legislature of this State for the purpose of promoting "Agriculture, Commerce, Manufactures and the Arts."

And whereas, the prosperity of each and every of these departments of industry is greatly dependent on safe, cheap and easy travelling and transportation, especially in respect to our farmers in the interior, also in respect to our manufacturers and artisans, the materials of whose fabrics are to a great extent procured and transported from distant markets and places, and returned again in the manufactured goods. And whereas, the merchant also is deeply interested in internal improvements, as by means of roads and canals production is greatly increased, and the materials embraced by mercantile operations are thereby made more abundant, and the facilities for the purchase and sale of those materials proportionably multiplied.

It was therefore resolved, That the interests of the farmer, merchant, manufacturer and artisan, require that internal improvements should advance, and that no considerations of false economy should be permitted to arrest their progress, but that adequate expenditures ought to be made at once in order to obtain the benefits arising from internal improvements by means of Railroads and Canals, wherever the country will admit, and the wants of the people require such facilities.

Resolved, That these expenditures will be doubly repaid to the state and people; first, in the income received from tolls, and secondly, from increased agricultural production in those fertile sections of this state whose distances from market render the fruits of farms of little value, and in the establishment of extensive manufactories on never failing streams whose waters are now running to waste, and in extended commercial operations and dealings, and in new and vigorous efforts of industry which the expenditures in improvements will inevitably produce.

Resolved, That in order to enable the friends of internal improvements to act with concert and efficiency, a convention be re-

commended to be held at the city of Utica on Wednesday, the 11th day of November next, at 12 o'clock, M., and that it be continued in existence by adjournment and further election of delegates, until its objects shall be fulfilled.

Resolved, That the several cities, towns, counties, and manufacturing and mechanic incorporations, for the advancement of agriculture, commerce, manufactures and the mechanic arts, in this State, be respectively and respectfully invited to send delegates to meet in the aforesaid convention, to be selected from the most able and best informed of our fellow citizens.

Resolved, That the foregoing preamble and resolutions be published, and that the publication thereof be and the same is hereby declared to be an invitation to our fellow citizens, included in the above description of persons, to appoint and send delegates accordingly.

EDWIN WILLIAMS, Res. Sec'y.

P. S. Editors of papers friendly to internal improvements, are requested to publish the foregoing.

[From the Maine Farmer.]

**CANAL MEETING.**—In compliance with a public notice, a large number of the citizens of the several towns of Farmington, Chesterville, Livermore, Fayette, Wayne and Gardiner, assembled in Fayette on the 3d inst.

The meeting was called to order by E. SMITH, and the object of it stated. MOSES HUBBARD, of Fayette, was chosen Chairman, and ENOCH SMITH, of Fayette, Secretary.

**Voted,** That a Committee be appointed to ascertain and cause an immediate survey to be made of the most feasible route for opening a communication by means of Railways and Canals from Winthrop Stream, through Wayne, Fayette, Livermore, and Chesterville, to Sandy River.

Henry W. Owen of Wayne, Ezra Fisk of Fayette, James Wing of Wayne, Capt. Cyrus Foss of Wayne, Josiah Chancy of Chesterville, Dr. H. G. Allen of Wayne, Thomas Haskell of Livermore, Reuben Lowell of Chesterville, Lewis Hunton of Livermore, Daniel Fifield of Fayette, John Morison and Joseph Ware of Farmington, were chosen a Committee for that purpose.

A statement of a survey from Kennebec River to Wayne Mills was made by Mr. P. Sheldon of Gardiner, and the utility and importance of Internal Improvements warmly urged. Communications were also made by gentlemen from various sections of the contemplated route, and a lively interest manifested in the undertaking.

**Voted,** That the proceedings of this meeting be signed by the Chairman and Secretary, and published in the Maine Farmer.

**Voted,** That this meeting be adjourned to meet at the Baptist Meeting House in Fayette, on Thursday the 22d of Oct. next, at one o'clock in the afternoon. Per order, MOSES HUBBARD, Chairman.

ENOCH SMITH, Secretary.  
Fayette, Sept. 3, 1835.

[FOR THE NEW-YORK AMERICAN.]

As the attention of our city authorities seems directed to the subject of paving the streets, it has occurred to me to suggest a mode different from any in use in this country, and which yet seems

more applicable than any other to our city. This is the system of laying flat cut stones, nicely jointed, for the wheels to run on, leaving the rest of the road in its present condition. In Broadway there might be four rail-ways—if I might so call them—of this nature; two for carriages ascending, and two for those going in the other direction. The effect of this system would be to keep vehicles to their proper side, more than is now practised, and to obviate those disasters so common in our streets. The wear and tear of horses and carriages that would be saved by this mode of paving, would be immense, and would soon repay the expense of the alteration. If it should be objected that these rail-ways, by keeping vehicles in rows following each other, would reduce the whole of drivers to the same gait, it may be answered, that after all, the pavement would be no worse in this respect than it is now; but that, on the contrary, in consequence of the greater order, it would be much easier for fast drivers to turn out. It might, moreover, be advisable to confine loaded vehicles, going at a walk, by law, to a particular portion of the road.

This plan of paving is neither new nor speculative. The streets of Milan are all laid in this way, and those who know that delightful city, will join me in attesting the ease with which they are traveled. In London, moreover, the road from the West India Docks to Wapping has been furnished with a track of this description, by means of which a single horse is able to draw a weight of sugar, which four would not be able to move on the ordinary pavement. X.

**CITY AFFAIRS.**—Under this head we publish a communication to-day, that appears to us to present some most important views, as to the necessity of immediately improving the streets, and avenues of the upper part of the island.

It is in this way that lots distant from the thickly settled parts of the city, may be put within the reach of mechanics and young beginners, who have their fortunes to make, instead of compelling them, by high rents, to seek dwellings over the rivers that bound us.

A railroad too, that should bring people down into the heart of the city, is now, we are well satisfied, a desirable improvement. We thought otherwise when such a scheme was first proposed, but the impassableness and dangers of Broadway, by reason of the omnibuses and other vehicles, which constantly crowd it, have convinced us, that rail cars, following a given track, from which they cannot deviate, drawn by horses, and announced by bells, as in the sleighing season, would be altogether safer, more convenient, and more advantageous to up-town residents.

[FOR THE NEW-YORK AMERICAN.]

**CITY AFFAIRS.**—The recess, which the members of the Common Council took during the month of August, has probably enabled many of them to notice the improvements in contemplation, in the different towns and cities in this section of the Union. They could not have failed to observe that the provisions, as compared with their respective present populations, for future increase, every where else, vastly exceed what our own city exhibits. I have not seen the returns of the census now taking, but computing our population according to the number of lots assessed as occupied, it cannot be less than 285,000, or an increase of 40 per cent. since the census of 1830, which gave 202,980. Supposing the population to advance in the same ratio for the next five years, there will be during that period one hundred and twenty thousand new inhabitants. The rule adopted by the Water Commissioners, in making their estimates, was to calculate 9-5 persons for every lot of 30 by 70 feet. As the city advances, the ordinary size of lots is enlarged, and many new houses will require more than one lot. It would probably be fair to suppose that in the present 12th Ward, lots will be at least 25 by 100 feet, and that therefore 12,630 lots will be required for the occupation of 120,000 persons; that is to say, of the next five years' increase. Not only will these be wanted, but, at least, 3000 more for churches, public squares and edifices, including reservations for receiving reservoirs, coal

and lumber yards, &c. &c. It is also to be borne in mind, that, owing to the disputed titles, and the desire of proprietors to take advantage of the enhancement growing out of their neighbors' improvements, a large amount of lots are for years, kept out of the market for all building purposes. There are between 23d and 57th streets, the 1st and 10th avenues, only 18,836\* lots, which will exceed the additional number required for the next five years, including the computed provision for public purposes, by scarcely more than 3000 lots. It is, therefore, reasonable to conclude that, even if our commercial prosperity does not advance at an accelerated rate, the neighborhood of 57th street will, in five years, be more densely populated than that of 23d street (where the prices, according to locality, range from \$1500 to \$3000) now is.

What arrangements are made to meet the wants of this new population? The graduation of lots is not legally established above 33d street, and even the adoption of the plans, which have passed one Board, would be but a very partial provision for the growing wants of the city. Some even of the streets below 23d street, and most of those above that line, are as yet unopened by law. Should the corporation now order, as proposed, all streets below 42d street to be opened, judging from the time consumed by the Wooster street and other Commissioners, years must elapse, according to the present system, before any thing effectual is done. In many cases, even when the dilatory action of the commissioners has been overcome, no progress has been made towards giving a practical operation to the legal proceedings. Thus, in May, 1833, Union Place was opened by law, and assessments paid by individuals to the amount of a quarter of a million of dollars, yet it was not till the autumn of 1834 that any provision was made by the public, for enclosing and embellishing the square; and though the importunities of individuals have at last been so far successful, as to induce contracts for the necessary coping, &c., to be entered into, there is no prospect that any thing effectual will be done, to point out where the square is, till three years have elapsed from the time that the assessments were actually levied. Even when contracts are formally made, their execution, as in the case of 14th st., and of the paving of Union Place, is allowed to be delayed for months with impunity. It may, indeed, be well for landholders to inquire, whether it is not the duty of the Street Commissioner to impose the stipulated penalty on the contractors, and thus diminish, *pro tanto*, the tax to be levied on the parties liable to be assessed for the improvements, and who are the real sufferers by the delay.

Again: the convenience of the people of Yorkville, and of a large adjacent population, who were obliged to go a mile and a half to a dock at the foot of 54th street, in order to obtain their fuel and other supplies furnished by water, led, several years ago, to the opening of 79th street to the East River. Yet, although the assessments on the adjacent property have been long since paid, there is nothing even now to distinguish that street or road from the neighboring fields.

Let any man visit Brooklyn, or Williamsburgh, (to say nothing of Boston or Philadelphia,) and compare the works there going on, with the perfect inactivity everywhere manifested on this island. The few laborers who are employed, seem to be engaged almost exclusively on the old roads, where their work is in a great measure useless, inasmuch as these irregular lanes are unknown to the legal map of the city, and must be closed on the opening of the Avenues. If complaint is made to the public administrators, by citizens whose whole fortunes are staked on the prosperity of this great commercial emporium, the only reply which is vouchsafed is, that "Brooklyn and Williamsburgh pay higher wages than we do, and therefore take off all the hands." It is obvious that if wages have risen, we must pay as others do, and no one can regret that every class of citizens, should participate in the exuberance of our prosperity. It is infinitely better for the owner of property, by whom in most cases the expense of public improvements is exclusively borne, to contribute a little more than formerly, and have the work promptly done, than it would be to have the streets in front of his lots gratuitously graduated and paved, half a dozen years hence.

\* In this calculation, allowance is made for intermediate avenues between the 3d and 4th, 4th and 5th, and 5th and 6th Avenues, two of which have already been partially established by law.

To the prosperity of the city the difference is incalculable.

Much has been said, during the last two or three years, in the Common Council, by the representatives of the upper wards, as to the importance of placing the Custom-house in a more central position, and against increasing the facilities of communication with Brooklyn. The writer of these remarks has always believed that in the great commercial emporium of the United States, provision should be made for the office of government, on a scale of magnificence commensurate with the revenue received here, and the future, as well as present, business of New-York. He has, also, been of opinion, that, while the people of the opposite shores have their places of business within our corporate limits, and derive from this city their means of living, they should be made to contribute proportionably to those expenses, which are incident to the seaport, by which they are sustained.—But so far as regards the bearing of these matters on the prosperity of the city, or of the upper wards in particular, they are insignificant in the extreme, compared with the importance of giving efficiency to the Street Commissioner's department. Where are the lots on this island, the graduation of which is settled, and which are susceptible of immediate occupation, that are within the reach of men of small means, and who wish to put up houses for their own accommodation? Scarcely a lot, on the streets opened by law, and within the range of graduation, can be purchased for less than \$1,500 or \$2,000. Hence, by our own acts, a large portion of our industrious population are driven to the opposite shores, and New York is deprived of citizens, whose future accumulations, though deduced from our unrivalled position, will never contribute to the alleviation of our city taxation, or to the augmentation of the property of those, on whom falls exclusively the burthen of sustaining the commercial emporium.

It is not intended by any thing here said, to derogate from the merits of the present Street Commissioner, who, it is understood, is about to retire from an office, for which he undoubtedly possesses eminent qualifications. But, views of policy and a system of organization, which would suit a town of 60,000 inhabitants, are scarcely adapted to a city of 300,000; and if the officers of the Corporation have not kept pace with the advance of our city and country, they have only erred in common with most of the men of the last century. The time, however, has arrived, when it is necessary for our municipal authorities to arouse from their lethargy, or to acknowledge as sober realities, what we have been accustomed to regard as the visionary dreams of our neighbors—that "the sceptre has already departed from Judah," and New York become a suburb of Brooklyn.

A NEW YORKER.

*A Dissertation upon the Running Gears of Railroad Carriages—illustrating some of their most important natural Mechanical Actions, inseparable thereto; and also describing a remedy for the evils set forth in the Dissertation, embracing principles not heretofore known. Also, a concise description of a Turning Platform for Railroad Carriages—a Curvature to turn corners of streets, wharves, &c., and Grooved Rails for the Curvatures, and the general use of the streets. Also, a newly invented Wrought Iron Wheel, for Railroads.* By JAMES STIMPSON.

(Concluded from our last number.)

*The inclination of loose wheels to gather in at the bottom if conical, and the ill effects resulting therefrom, &c.*

Again, wheels that are formed in the least conical upon their treads will incline or gather in towards each other at their points of contact with the rails, in the same manner as a leather belt inclines to the largest part of a pulley, and with a power equal to that of the adhesion of the wheels to the rails. This tendency to run in has no other effect upon wheels made fast upon their axles, when both they and their axles are sufficiently stiff or strong, than to keep them upon a constant strain inwards at their points of contact with the rails, and to bend or

spring the axles upwards; but upon wheels loose upon their axles the effect is almost incredible, the power exerted upon the axles at the exterior edges of the naves is equal to three thousand and six hundred pounds; for in medium sized wheels the leverage power of the periphery over the inside of the nave is as twelve to one, by which if we multiply the estimated power of adhesion of one wheel, or three hundred pounds, we obtain the result aforesaid. It must be evident to any one that such a power constantly exerting itself, or in other words, grinding upon the axles at the exterior edges of the naves, must soon wear them larger outward from their centres each way. It may also be observed that every time the wheels turn round there must be a constant tendency to oblique from a perpendicular line, if there be any loose play between the naves and axles; for the sides or points of the wheels, which were last in contact with the rails, were of course within a plumb line through their centres when compared with the sides or points immediately above—and they must be as much without that plumb line when at top as they were within at bottom—so that in changing from one position to the other they must be constantly obliquing. Now as three feet wheels turn around five hundred and eighty-four times in a mile, the gripping force as before set forth of three thousand and six hundred pounds is constantly acting upon them in addition to the weight of the load, the carriage, and the power necessary to manage and control the wheels—so that no one can be at a loss in accounting for the early and rapid destruction of the naves and axles, when the wheels are left loose, or for that of the collars and washers within which the naves revolve; and more especially when it is considered that all these movements at the naves, besides being under such a stress of power and weight, take place in a situation extremely exposed to the deposit of dust and dirt; for the wheels generally run so fast that the dirt is thrown from their peripheries up against the carriage or covers of the wheels, and even into the air, whence it falls upon the axles, there to mingle with the oil, to work in between the moving surfaces about the naves, and necessarily to impair them very fast. Thus they soon become so very loose upon their axles as to render their passage through a crossing or round a curvature extremely dangerous.

And again, a mere trifle of loose play between the naves and axles, allows considerable variation from a perpendicular at the peripheries of the wheels, and thereby cause their treads, although conical, to lay flat upon the rails: from whence it necessarily follows, that as much as the inside of the tread is larger than the outside, so much the outside has to be slipped along over the rail to a great loss of power and extra wear of both wheel and rail. To obviate these difficulties in part, one wheel has been made fast upon each axle and the others left loose; but practice at once proved that the stress upon the loose wheel was quite doubled, and its destruction made rapid in proportion—and the use of loose wheels has been abandoned on account of the cost of repairs, and their total inability to guide the carriage.

Thus it is manifest that the natural tendencies of loose wheels are to their own rapid destruction, and that therefore they are inapplicable to the use—and the only remedies supposed to be left to obviate some of the principal difficulties that have been enumerated, was to be found in the use of

vibrating axles or small wheels made fast to the axles. It is well known that by a reduction of the size, the stress at the axles would be reduced, and that the risk of breaking them, when it became necessary for any of them to slide, would also be reduced; and this effect was necessarily produced by the change. But they are after all subject to all the extra wear produced by sliding, and to the stress upon the wheels, axles, keys and carriage, which has been already alluded to; that is exactly all that stress in proportion to their size; while at the same time their liability to run off the track is proportionate to the difficulty of changing their line of direction upon the rails at the commencement of a curve.

*Vibrating axles—the bad tendency thereof, &c.*

I have before said there was an impropriety in using them, and it may be proper here to give the reason. I will first however call attention to the usual and necessary play allowed between the flanches and the inner edges of the rails—this play is about an inch and three quarters, more or less, but the less the better, where the curvatures of the road will admit of it, as from a proper attention to this point alone greatly depends the injury to the road, the carriage, and the liability of running off the road. For example, we will suppose the flanches of the fore and hind wheels, upon the diagonal corners of a carriage, whose axles are confined in a parallel position, to be close up to the rails each way, and that the axles are coupled three feet six inches apart, consequently all the angle across the track that could ever be formed, would be that of one inch and three quarters to forty-two inches; this angle is so slight that when the flanches do touch, their power of action either to injure the flanch or rail, or to spread the rails apart, is of course lessened in proportion to the acuteness of the angle; this position being well understood, that which follows will be fully comprehended. Now with vibrating axles there is need of as much loose play between the rails and the flanches, as is allowed to fix axles, and even twice the distance is allowed; let it be more or less, it is certain that when the axles are allowed to vibrate sufficiently to conform to the plane of the radius of a circle of four hundred feet, and when the fore axle is up to the extreme limits of its vibration on one direction, if the other is exactly square with the frame of the carriage, the angle of the other with the track would be twice as obtuse as the one with fixed axles can be in the same relative position; but if the hind axle was thrown in a contrary direction to the front, which must and often will be the case, even by their own action or the formation of the track, and very often from extraneous causes, such as impediments to motion upon the rails causing a slipping, &c.; then the obtuseness of the angle becomes three-fold, or in other words, it has three times the power to run off the track that the fixed axles have.—Should this position of the axles happen just at a crossing or curve in the tracks, and the curve be across the set of the wheels, then the course of the wheels would be almost at right angles with the line of the road, and the power to run off the rails six times as great as the fixed axles. It also follows that the power to spread open the track is increased in the same proportion, for when the flanch is locked or hard up to one rail, it can go no further in that direction, and the wheels upon the other track act with all their power of adhesion to

force the rails apart; hence the lateral strain upon the boxes, or if friction wheels be used, the lateral pressure will be against their backs, acted upon by the ends of the axles, all of which has a powerful tendency to rack and loosen the joints of the carriage; for whenever one axle runs across the other, a constant slipping of the carriage transversely upon the axles takes place, and the lateral pressure against the shoulders of the axles, if they have any, and sides of the boxes, or against the back of the friction wheels, by the ends of the axles, is far more than can well be imagined until the principles of the action is well understood, or the powerful and destructive effects shown by examining the parts. I have seen many backs broken out of friction wheels from that cause alone, vibration—and the greater the play allowed between the ends of the axles and the backs of the wheels, or the shoulders upon the axles and boxes, the greater will be the damage; for the carriage will slide off and on transversely upon the axles, with all apparent ease, as if it weighed but a single pound.—It must be obvious that the greater distance such heavy weights are allowed to move, the more violent will be the injury here spoken of when bringing up. My joint is a perfect remedy for this evil, as my experience has demonstrated.

There are other considerable objections to the use of vibrating axles, to which it may be proper here to allude. They will keep vibrating almost constantly, and cause a continual chafing of the wheels and rails, which the fixed axles would not, producing a very unpleasant sensation upon the minds of the passengers. This constancy of vibration arises from the obtuse angles or rank shear the carriage wheels obtain across the track; for it is certain that one rank shear cannot be overcome or mended without making another, and this is owing to the fact that they must run up a greater distance upon the cones to overcome the shear than the track itself requires; it therefore turns off not exactly upon the line of the road ahead, but across it, and there it meets with the same difficulties, unless it has passed upon a piece of road favorable to its true adjustment. But should the road be unfavorable to such adjustment, then the vibration, and consequently the difficulty, would be increased double, and often three-fold—this could never take place with fixed axles. In order further to illustrate this position, and to show the true cause of this vibration, which is to be found in the position of the carriage or axles, we will suppose the range of the axles to deviate ten degrees from that of the track, and that both axles are parallel to each other, it necessarily follows that the front wheel which first arrives upon the cone, cannot change the direction of its axle, until it runs far enough to gain upon its fellow sufficiently for that purpose, and also to overcome the obtuse angle the carriage or the hind axle had at the outset; so that the distance the carriage will go ahead before it can turn off is much farther than was necessary to properly adjust it to the true range of the track; that is, when the front wheel had arrived upon that part of the cone proper to run the track, the hind wheels had not, and the front consequently has to run enough farther ahead, still upon an oblique direction, to adjust both points, and thus overreaches its proper position by forming a circuit as it were in making the change; and thus having gone too far, it of course turns off the contrary way, and then ensues the same difficulties as before, and

so on continually. All that can be said in favor of vibrating axles is that in certain situations they will prevent a slipping of the wheels upon the rails; but the extra wear from the more frequent vibrations, the loss of power, and above all the great liability to break the flanges and to run off the tracks when under much speed, will by far outweigh all the benefits they possess. To use vibrating axles with friction wheels is contrary to the generally received and common understanding of mechanical principles, at least so far as I comprehend them. Indeed the absurdity to my mind is so great that nothing but having actually seen it in use would have induced me to believe it.

*An experiment to prove the transverse inclination of conical wheels.*

I am aware we have been told by very learned gentlemen in mechanics that when the axles and wheels are so stiff that they cannot spring or give way in any perceptible degree, that the tendency of the wheels to incline or gather at the bottom could not take place, or the separation of the rails ensue, because, say they, when there is a little or no inward movement, no such effect can be produced. I cannot however see it in that light, for I have applied means, and put myself to some expense to try it in a way that cannot deceive. I will here state the result of my experiment, that others may be the better able to judge. In a horse locomotive which I invented some years since, I had wheels four feet in diameter, cast iron naves, wooden spokes and fellows, their peripheries were turned in a lathe perfectly round and cylindrical, and then tired with rolled iron plates, the flanges bolted upon the sides of the fellows, so as to make them very strong; the hubs were drilled out to fit close upon the axles, and each wheel was revolved upon its axle between collars and a cap: the cap was fixed fast upon the axle, outside of the naves, by a strong key running through it and the axle, and was made as large as the outside of the nave of the wheel; both were turned true and faced up to each other; within each of these caps were two catches, which acted against rack teeth in the face or end of the nave, to turn the wheel. The power of action being applied to the axles, the catches turned the wheels as fast as the axles, but they could turn faster at all times when necessary. In 1829 and '30 I run it with the peripheries entirely cylindrical, and it went perfectly smooth, still, and free from any lateral movement or pressure. Being so well prepared to carry out or prove my views in regard to the transverse action or conical wheels, I paid Mr. George Reader 25 dollars to turn the tires conical. I put them to work, and the instant they started they inclined inwards at the bottom. They had not revolved fifteen times before they made a jump outwards, (to do which it was necessary to overcome the whole adhesion of the wheels to the rails,) and so continued to act as long as I used them; that is the wheels would run in towards each other at the bottoms until the strength of the spokes and rims could no longer yield, and they would then spring outwards to a vertical position. I could perceive there was an easement to forward motion the instant the wheels were upright by the movement of the car, much the same as is observable in steamboats by the engines passing their dead centres. The retardation of the car arose from the outside of the wheels being smallest, and of course having to be slipped upon the rail, while they touched upon the whole width of it, as much as the outside

of the wheels were smaller than the inside. As soon as the wheels were upright the greater part of the resistance was removed, as the bearing surface was contracted.—The powerful effect of this action inwards, pressing the naves of the wheels against the collars and washers, was such that I found it necessary to put in washers an eighth of an inch thick nearly every ten days of use, to prevent the wheels from falling in between the rails. Mr. Washington, of the firm of Majors & Washington, made the washers, and he saw and knew the cause of the destruction: I mention his name that he may be applied to if desired. I am well convinced that the damage at the nave and upon the axles, collars, &c. of loose wheels, is so great, (unless their diameters be very small,) that the advantage of their not slipping cannot compensate for the additional cost caused by their speedy destruction, and more especially if the treads be in the least conical.

Let us next inquire why they run in when conical, and not, when cylindrical: The naves being six inches long, drilled out straight in a chuck lathe, and the weight of the carriage, with two horses, and three to fifteen persons, one would think, resting upon the inside of the naves, would certainly have some tendency to keep the wheels upright; for when out of plumb, the bearing, if there were any loose play in the naves at all, must be upon the extreme inner edge of the hub, requiring some power surely to raise it in that position; at the same time the naves were placed between the cap and collars, and keyed up as close to each other, when first in operation, as they could be. Their running in notwithstanding shows that there is a natural mechanical tendency to run in, whether the strength of the wheels and axles yield to it or not, especially when it had to overcome a very great opposition, at the very instant it commenced.

I should prefer to have all that part of the wheels outside of the cone entirely cylindrical, there being but one part of the road where they can be injurious, and that but a small portion of it, and even there it may be remedied by a proper mode of forming the iron plates; the portion of the tracks to which I allude, is the inside rail of a circle. When a cylindrical wheel turns upon a flat horizontal rail the bearing in contact will extend across the whole width of the rail, the outer edge of the inner wheel must therefore be retreating, or twisting, as it rolls around the curve, nearly as much as the outer edge of the rail is shorter than the inside; but if the inside rails were rolled with an elliptical face, or made thickest on the inner edge, then the bearings might be contracted as much as it might be desired. Under this mode of construction the difficulty would be removed. Should the rails become worn down flat, the cones would also by the same time wear away the inner edge of the outer rails; the rails would then only require to be changed, one for the other, so as to re-instate them nearly as at first.

*A reference to common coaches, so as to understand the use of the joint, &c.*

Having described the nature of some of the most remarkable and important difficulties that exist in the operations of wheels as now used upon railroad carriages, which it is the object of my improvement to obviate, it may be proper to make a few remarks upon its utility and easement to motion, in order to make its merits obvious and familiar to those who may not have had an op-

portunity of becoming acquainted with the operations of railroad carriages: and I will illustrate the subject by reference to the operations of common coaches. In these it is well known, that the pole at the fore axle is the means by which all the wheels are guided, that all the wheels are loose upon their axles, and that when going in a curved line or direction, the hind wheels follow nearly in the track of the fore ones. Now it will be easily comprehended, that when turning a curve, the wheels upon the outside of the curve must necessarily turn round faster than those upon the inside, because they have to run a greater distance. But suppose the wheels upon the hind axle were made fast; in that case, the wheel upon the outside of the curve, instead of rolling faster, would be dragged along as much as the distance described by the wheel on the outside exceeds that described by the wheel upon the inside of the curve, or if this does not take place, the inner wheel must slide back: for one or the other must necessarily slide, and in either case the stress upon the naves and axle will be the same, and the necessary extra power to turn them, just equal to that of slipping the wheel.

We will now apply the same facts to wheels on a railroad carriage geared according to my improvement, and consider the cones upon the fore wheels, both of which are to be made fast to their axle, as the pole of the coach, and the joint in the centre of the hind axle, as a substitute for the loose wheels on the coach; and it will be readily perceived that the carriage will then turn a curve with the greatest ease; for the joint in the hind axles permits the hind wheels to act independently of each other, and thus enables one to describe a greater space in the same moment of time; thus preventing the necessity of any dragging or sliding of the hind wheels, and thereby leaving the cone of the fore wheel in possession of full power to guide the carriage in the direction of the track: which it will be able to accomplish with as much ease and certainty, as a coach is guided by means of the pole. With this joint the cone of the fore wheel will be much more efficient in guiding the carriage than it would be, if, instead of the joint in the axle, the hind wheels were left loose upon their axle—for when the wheels are made fast, the axle, although it have a joint in its centre, turns with the wheels as if it had no joint, and the bearings of the axle are but two inches in diameter: but when the wheels are left loose, the diameters of the bearings of the axles within the naves of the wheels are required to be nearly three inches, which, by increasing the amount of surface in contact, increases the resistance to the revolutions of the wheels in the same ratio—to which should be added the friction at the end of the naves, against the collars and washers, and the gripping or grinding power of the naves upon the axles, produced by the inclination of the wheels to run in at their points of contact with the rails, as before stated, together with the effect produced by the weight of the load and carriage. It will then be clearly perceived by comparing the two modes, that the hind wheels will much more readily conform to the movements and guidance of the cones upon the fore wheels, when they are made fast upon an axle with a joint in its centre, than when they are left loose upon an axle without a joint—for at the joint there is no friction of importance produced by the superincumbent weight. Indeed the hind part of the carriage by means of the joint will yield to the action of the cones as easily as if centred upon a pivot.

It is also worthy of remark, that the joint is two feet and nine inches from the centre of the wheels at their naves, so that it possesses a leverage power, proportionate to that distance, to hold the wheels in an upright, steady and firm position, and save itself from being cut by its own slight movements.

What then can be more simple, safe and consistent in its practical operation and effects, than this joint, to consummate that grand object for the attainment of which such a multitude of changes in the mode of gearing wheels have been made both in Europe and America since the first introduction of railroads—and without it, those changes would necessarily continue to go on; for it has been abundantly evident, that when the durable nature of the materials made use of is taken into consideration, a sufficient remuneration in their increased duration has not been realized. But on the contrary it has been manifest, that there existed some hidden cause of destruction, far exceeding that to which carriage operations upon common roads are comparatively liable.

I have thus endeavored to point out as distinctly and concisely as possible the difficulties necessarily attendant upon the operations of the wheels of railroad carriages as now geared and used; and I am satisfied that the remedy I have provided will be amply sufficient to accomplish the object for which it is intended, and that when carried into operation, it will prove entirely satisfactory and become the standard in future operations. I flatter myself that no further alteration or amendment will be requisite, for nothing can surpass it in simplicity and efficiency. For a period of more than four years, I have been engaged more or less in testing its utility in practice, and I am certain that I cannot be laboring under any delusion or mistake as to what I have stated in relation thereto. I have forborne to give publicity to this improvement hitherto from a desire to prove its utility and practical efficiency to my complete satisfaction at my own leisure and expense, as well as to give time to others to try their different projects, that they might perceive how difficult, and yet how important it was to provide a remedy for the difficulties which they have been laboring under, in hopes that when made known they would be the better able and the more willing to appreciate its value when understood and realized.

#### Formation of Wheels, &c.

Before closing my remarks I will observe that the peripheries of the wheels should be made perfectly cylindrical or horizontal as to all that portion thereof designated and known as the tread, and that the inclination and breadth of the conical part of the peripheries should vary according to the radii of the curves in the tracks on which the wheels are intended to run—and the distance between the foot of the cones on each side of the carriage, when it is standing centrally upon the rails, must be a trifle less than the distance between the inner edges of the rail plates; so that running on a straight line of road no portion of the conical part of the peripheries of the wheels shall come in contact with the rails.

My reasons for preferring this form of wheels are, that when running upon their treads or cylindrical faces, which they will always do when the road is straight and both rails are equally level, they will have no tendency to run in towards each other at their points of contact with the rails; and that therefore the naves and axles will be relieved from the stress upon them, pro-

duced by that tendency when the wheels are conical—and that while running upon a curve, the cone, by the relief or easement to motion afforded by the application and use of the joint, will follow its own natural course upon the track, and thus all lateral strain will be obviated; and in no part of the operations will there be any sliding, if the wheels be made after the proposed form. When the treads are entirely cylindrical the top of the inner rail should be elliptical to prevent chafing. But particular care should be taken to have the size of the treads of the two wheels, which are to be fastened upon the fore axle, which has no joint, exactly alike as to circumference as it is possible to make them—for if they be unequal the smaller will be thrown upon the foot of its cone as much as will be required to equalize the circumferences of the two wheels, and thereby wear away or indent the face of the cone and leave in it an abrupt shoulder. No caution of this kind will be necessary with respect to the wheels upon the hind axle which has a joint, as the joint alone obviates all the difficulty. This circumstance affords a choice, for equality of size, of two out of every four wheels, to fasten upon the fore axle.

From all these circumstances the liability of breaking the axles or wheels, or of working them loose, will be reduced to a mere trifle. Indeed the hind wheels may be sufficiently secured upon their axle without the use of either keys or pins, by merely staking them up upon the outside of their naves, if the holes within the naves be made to receive the axle, and the axle itself be made a little tapering, that is, smallest at the outside. Even the breaks will produce no stress upon the axle or the naves of the wheels upon the hind axle; as a break can have no influence upon the wheel opposite to that to which it is applied.

I have left several minor points unnoticed, not feeling myself competent to do full justice to the subject; but have submitted to the task thus far from the necessity of setting forth the causes which called for my improvement; and have contented myself with touching upon the most important points, in hopes that the so doing would lead to a full development of the subject by those more competent than myself.

#### Description of the Joint.

The joint alluded to in the foregoing observations may be constructed in the following manner: The axle intended for the after part of the carriage should be made in two parts, to meet in the centre between the wheels, their ends upset sufficiently to form a flanch, in the finish, say one quarter of an inch larger all round than the axle, and about the same in thickness; they should be turned exactly of a size, as well as the axles outside the flanch, as far as the coupling box is intended to reach, and their ends made somewhat concave below, or a little within the base of the flanches, to prevent any leverage over the centres of the axles, to press them apart. The coupling box should fit the axles exactly, and have a groove turned into its centre sufficiently deep, and wide, to receive the flanches when placed close up to each other. The coupling box may be closed over the axles by screw bolts, and nuts; or hoops may be shrunk upon it, or drove on, and then cut up a little outside of the hoops, to prevent their slipping off, the box being formed a little tapering each way from the centre, with a projecting ring, or rib round, larger than what is turned out of the inside, to receive the flanches of the axles. Care should be taken that the coupling should be so

strong that when fastened upon the axles the strength at the points of junction, shall be equal to any part of the axles. The box should be about one foot long. One axle can thus turn independently of the other, and yet be so well fitted that it shall have no loose play in any direction, except to turn round. It will be seen that when running upon a straight road, if all the wheels were of equal diameters, which, by the by, is very seldom the case, there would be no movement of the axles within the coupling; and when running upon a curve, if the axle was two inches and three quarters in diameters, and the wheels thirty-six, it would there be only in movement, as two and three quarters is to thirty-six, while the distance the coupling is from the wheels, affords so much power over the wheels by leverage, that but a very small degree of stress within the box can be brought to act upon it. Now let us consider the effect of the steering power afforded by the joint: the hind wheels must yield to the slightest impulse, the cones then upon the forward wheels can direct the course of the carriage with nearly as much ease as though they were running by themselves independent of the carriage, thus steering a direct course with the road, and at the same time effecting what was contemplated by the use of vibrating axles, while it avoids the dangers resulting therefrom, and this too, with wheels all made fast to the axles, and the axles themselves kept perfectly parallel to each other, and thereby avoiding all the injury and loss of property resulting from the application of loose wheels, and saves as much of the propelling power in their movements as is necessary to make the wheels slip upon the rails. I have no doubt that one set of wheels with this improvement, will out last two sets, as now used upon roads as serpentine as that of the Susquehanna, or Baltimore and Ohio. No article so trifling in itself in use at the present day upon railroads, can in any way compare with it in usefulness. I have used it under all speeds up to thirty-three miles per hour, and could never perceive a difference in its action.

#### *Description of the Turning Platform, &c.*

It may be useful and satisfactory to mention that I have also obtained a patent for a turning platform, to turn railroad or other carriages upon. The platform turns upon a ring projecting underneath, resting upon the tops of twelve conical rollers, while the rollers themselves run upon the top of a cast iron ring of the same size, both of which are near to the exterior of the platform, so that there is no liability of its rocking about; and there is no friction worth mentioning, arising from the superincumbent weight of the carriage and load; which is in practice a benefit about the same as to enlarge the centre of a pivot, so as to extend to the exterior without increasing the friction. The main object of my mode of construction, is to secure a permanent level surface with the adjoining track rails with an easy movement which a centre pivot will not long do; for when worn a trifle at the centre it will cause a great deviation at the exterior from a level; and the foundation is far more expensive, and difficult to keep in repair, to insure a perfectly horizontal position, when acted upon by the centre of the platform only. Those laid in the centre of Pratt street in the city of Baltimore are of the kind above described.

I have also two patents for a mode of turning corners of streets, wharves, &c. One of them is for the application of the *flanches* for that purpose. It is effected by the wheels upon the outer track of the curve's

running upon their flanches, while the wheels upon the inner track, run upon their treads, which are about two and three quarters inches less in diameter than the flanches. The other patent is for the railroad plates necessary to form the curvature; and also for *grooved* rails for any parts of the streets, made of wrought or cast iron, so constructed that no description of carriage can be injured in passing in any direction over them. They are indeed a real improvement to the common travel of the streets, at the same time less liable to injury of themselves, than those of any other I have seen.

I have also invented a wheel for locomotive use, and especially for passenger carriages, which is no doubt superior to that of any other known, for the following reasons: From its peculiar formation it may be made lighter by one half; than any other, and at the same time twice as strong. It is composed entirely of wrought iron, excepting the hub, and no bolts or rivets are used in its construction, a desideratum long desired, and sought for. It will unquestionably become the standard for all the purposes where speed and safety are essential.

The daily line of steam packets between *Pittsburgh* and *Louisville*, have, as we learn from the *Pittsburgh Gazette* of 23d inst., resumed their trips—leaving *Pittsburgh* every day, but Sunday, at 9 o'clock in the morning. The navigation of the *Ohio* for the smaller class of steamboats, has not, we believe, been suspended at all, this season—though usually in the months of July and August it is.

NAVIGATING THE ATLANTIC BY STEAM.—Our readers will find in our advertising columns this morning, notice of an intended application to our Legislature for the charter of a company to be denominated "*The Atlantic Steam Packet Company*," the object of which is to establish a line of steam packets between this port and Liverpool.

We are happy to hear that Captain Cobb one of our most enterprising packet Captains has charge of this enterprise, and that it is intended to build vessels of about twelve hundred tons burden with two engines each. But little doubt is entertained of accomplishing the passage out in about twelve days and the return passage in about fourteen! We have long been satisfied of the practicability of propelling our packets by steam, and we congratulate the public upon the reasonable prospects of accomplishing this great object in the course of the ensuing summer.—[*Courier and Enquirer*.]

THE TWO BOAT RACES afforded yesterday a warm interest both on land and water. The first contest was easily won by the *Quebec Amateurs'* boat, the *Water Witch*, (Greenock built, by Nicol,) rowed by Messrs. Vaughan, Rogers, Young and Ferguson, and steered by Mr. C. Gettings, beating the *Musicaner*, a gig of the *Pique*, rowed by four Officers and steered by the Master. The boats rowed from the anchorage of the *Pique* to a boat moored on the *Beaumont* shoals, the distance, going and returning, being between four and five miles. The second contest was, however, the one which excited the greatest interest, in which the same boats were rowed by four seamen of the *Pique*, and four of the *Quarter Master General's* boat crew. Both boats kept nearly together in the whole distance, to their rounding the moored boat, when the *Musicaner* of the *Pique* shot ahead, and came in about 100 yards before the *Witch*, which had suffered in the heavy swell and contrary wind, and reached the frigate in a very damaged state.

The *Pique* was filled with citizens, and His Excellency Lord Gosford, Sir George Gipps, and Lady Gipps, together with a large number of military, were also present. The *Pique's* boat was received by hearty cheers as she passed H. M. ships President and Forte, and the whole crew of the *Pique* and all the visitors shouted with joy on her coming in first. The Officer in command had kept boats moving between the *King's Wharf* and the *Pique* to convey any one wishing to get on board, and the tables were laid in all the rooms,

and an excellent collation and wines were served to them. The visitors were afterwards landed by the boats, all highly delighted with the polite reception they had experienced.—[*Quebec Gazette*.]

The following address to the *Mechanics of Easton, Pa.*, will be found well worthy of a second, aye, of an oft-repeated perusal. It is in a style which every mechanic and every apprentice can understand; and it states facts which it is important for every practical man to know. It refers to individuals who have, by the force of talents, industry, and perseverance, arisen from obscurity and indigence to the most honorable stations in the history of the country and of the world; to men who have conferred benefits upon mankind beyond the power of man to estimate and appreciate; and, what is of more importance, it indicates the path by which they arrived at that station, and, therefore, the course for others to pursue who would become, like *Rittenhouse*, *Fulton*, and *Evans*, the benefactors of mankind.

*An Address to the Mechanics of Easton, Pennsylvania, delivered at their request, by JAMES MADISON PORTER, on the 4th of July, 1835.*

In comparing man with the rest of the animated part of creation, it will be found that his superiority consists not in his animal powers or capacities. He has neither the strength nor the speed that characterize the greater portion of the brute creation, and enable them successfully to attack or defend. He is, of all animals, the most helpless in infancy, and the least capable of enduring the changes of the seasons and the inclemencies of the elements. His imbecility and incapacity to take care of himself is continued through a long infancy, and even in the maturity and vigor of manhood, his physical powers are of an inferior order. Whence, then, does the superiority of man arise? It is from the mind, the immaterial mind, which enables him to lord it over the rest of creation, and make them subservient to his wants or caprices. Well then might the poet say,

"I would be measured by my soul,  
The mind's the standard of the man."

Philosophers have been much divided on the subject of the powers of the mind—whether the mind is a mere capacity for improvement which requires something to evolve it, or whether talents are innate. It matters, however, but little which is right. In either case the improvement of the mental faculties, by reading and study, develops its capacities and enables it to bring its resources into practical use.

In considering the subject to which your attention is now necessarily called, it will be attempted, in some slight degree, to trace the influence of mental development in relation to the mechanic arts—which at this day must be considered the most beneficial, practical illustration of natural philosophy, as applied to the ordinary useful purposes of life.

In the infant ages of mankind, the mechanic arts were little practised. Man's first lot was probably in the mild regions of the equator, where the great luxuriance in the products of nature, and the little occasion there existed for the erection of buildings to shelter him from the inclemency of the weather, or the procur-

ing of much apparel for the same purposes, were illy calculated to elicit the mechanical powers or principles lying like an unsprouted germ in his mind. Necessity has ever been the mother of invention, and thus we see that ere this globe was visited by that deluge which swept all the human family, but the favored household of Noah, from its surface, which had been overspread by wickedness, the necessities, the conveniences, or the curiosity of man, had induced considerable progress in the mechanic arts. We learn from the word of sacred truth, that in a few generations from the great progenitor of mankind, and perhaps even while he yet lived, cities were builded, musical instruments constructed, and mechanism in metals carried on. Cain built the city of Enoch—Jabal was the father of such as dwelt in tents and have cattle—Jubal of such as handled the harp and organ—and Tubal-cain an instructor of artificers in brass and iron.

At the period of the deluge, something over sixteen centuries and a half from the creation, there is no doubt that considerable perfection had been attained in many of the useful and practical branches of mechanism. The ark itself was perhaps one of the best specimens of art for the purpose for which it was intended, that ever was produced, for the great Jehovah himself condescended to be the instructor of its immediate maker; and wherever he has set an example of mechanical skill or arrangement, every thing merely human stands back abashed. Subsequent to the deluge which destroyed the earth that *then was*, and gave man this *new earth* which we now inhabit, and which exhibits so many geological proofs of the existence of that deluge, and the accuracy of the Mosaic account of the creation and early history of the globe, the mechanic arts were practised and extended, as the increase of the human family spread them abroad on the earth, as the extent of light and knowledge, and consequently the refinements of life, prevailed.

It would be out of place here to attempt a history in detail of their progress in the various arts and sciences. Much pains and labor have been bestowed on this subject to unbosom from the monuments or rubbish of ages the claims of nations and of people to the rank of pioneers in the works of art.

The cities of Babylon and Nineveh were built some 250 years before the time at which the best authenticated accounts fix the commencement of the first of the pyramids of Egypt; and the confusion of tongues at the attempted erection of the tower of Babel must have preceded the commencement of the first pyramid between 50 and 100 years.

The erection of the first of these pyramids is ascribed to Apachmes, the third of the race of shepherd Kings of Egypt, about 2,695 years previous to the birth of our Saviour, and some years previous to the time when the patriarch Abraham visited Egypt; and it is evident

from the skill exhibited in their structure, the immense masses of stone of which they were composed, the order and system with which they were planned and executed, as a consequence from which, they have endured, in defiance of time and the elements, until the history of the men and nations that reared them has been nearly lost to the world, and only known by the unravelling of the hieroglyphics which abound in them, that the principles and practice of permanent and durable architecture had then attained to considerable perfection, and that much of mechanical skill must have been used in removing the material from the quarry; in conveying it to and depositing it on the building, and in dressing and finishing each block for its appropriate place.

It was not, however, in architecture alone, that the advance in the mechanic arts was exhibited. From the rude coverings of skins, the first garments worn by the ante-diluvian world, subsequent to the expulsion, the ingenuity of mankind had invented the construction of fabrics as well for garments as for tents. Subsequent to the deluge, and as far back as 1850 odd years before the Christian era, when Eliezer of Damascus was sent by Abraham to the land of his brethren to obtain a wife for his son Isaac, he takes with him golden earrings and bracelets, as presents for the intended bride, and we find them having pitchers and other utensils of convenience in housekeeping—and the bride, when she met her future husband, was veiled.

The making of bricks, we have authentic accounts, was in use more than 2000 years before the Christian era. The erections of the buildings before mentioned—of the ark by the Israelites in their journey—of the various heathen temples of Egypt, Greece, and Rome—the splendid temple by Solomon—and the Colossus at Rhodes, with other instances among other nations, until the overthrow of the Roman Republic, and the establishment of the Empire, show, that at and before the Christian era, great progress had been made in various arts, tending to minister to the necessities and luxuries of mankind.

The Grecian models of architecture have never been excelled in elegance. The Greeks understood the laws of proportion in the construction of their edifices, in an especial manner. Yet there were many principles in natural philosophy little, if at all, known to them. The principles of hydraulics, which are not yet fully known, were then even less perfectly understood. They knew not that water would rise to its own level; and hence, instead of the simple modern resort to conduit pipes, they incurred immense expenses in rearing arch piled upon arch, to construct their aqueducts to carry large supplies of water over depressed spots of ground.\*

Archimedes flourished about 280 years

\* Pliny informs us that water can be raised by tubes of lead, and the excavations at Pompeii would show that, at and before the reign of the Emperor

before the birth of our Saviour. Whatever might have been known in practice previously, there was little of the theory of mechanics philosophically understood. He has the credit of discovering the exact operation and power of the screw, the inclined plane, the pully, and the lever—of the latter of which he was so enamored as to say to the second Hiero, King of Syracuse, "Give me a place to stand on, and I will move the world." And yet it would seem that these, or some at least of these powers, must have been in use among the Egyptians some fifteen to eighteen hundred years before, or how could the immense masses of granite and other stone forming the walls, the columns, the colossal figures, and other monuments of ancient Memphis, Abydos, Antæopolis, and Thebes, ever have been raised from their natural beds, and transported to the temples, the grottos, the sepulchres and other edifices which they, in part, composed or decorated?

From the days of Archimedes onward, the science of mechanics was taught in the schools. The philosopher and mathematician searched further into the theory, whilst the result of their investigations was put in use by practical artisans, and submitted to the unerring test of experience. In the dark ages, which succeeded, as the Roman Empire declined and fell, and ignorance and superstition wrapped the world in their sable habiliments, there was little of improvement in the mechanical branches of science, and little of practice, except in the branch of architecture, and those domestic arts with which the world could not dispense.

It was not until towards the close of the 16th century that the rapid development of the physical sciences commenced; and there is not perhaps on record in history any more extraordinary contrast than that of the slow and limited progress of those sciences, from the early ages of mankind up to that time, and the rapidity with which they have since been enlarged and spread abroad.

Until the art of printing was discovered and put in practice, the additions to the stock of knowledge on all subjects were few and far between. The mass of mankind were little interested in them, and if the observations made and the knowledge acquired by a few enquiring minds in any age were not lost in oblivion, they were not spread abroad. It seemed to be a part of the philosophy of the ancient and the monastic school to keep their knowledge wrapped up in learned mystery, as a thing too sacred for common observation. It was not then supposed that the sciences could exist in, and be illustrated by, common objects, and have a place in the Mechanic Arts. But, no doubt, many a bold and adventurous mind did push its enquiries beyond the ordinary routine, and taking its flight into the regions of speculation, made

Tides, baths and fountains were thus supplied. But even among the Romans they knew no material of sufficient tenacity for large supplies of water, & they could suppose that conduit pipes could be cast on so large a scale.

valuable observations, which failed to benefit mankind, because they perished without a record. Towards the middle of the 16th century, this art of printing, of all others the most valuable to mankind, was discovered, and by the commencement of the 16th century, had come into pretty general use, and enabled every one to make his ideas known to the world. On this subject it has been well said: "The moment it took place, the sparks of information, from time to time, struck out, instead of glimmering for a moment and dying away in oblivion, began to accumulate into a genial grow, and the flame was at length kindled which was speedily to acquire the strength and rapid spread of a conflagration. There was an universal excitement in the minds of men throughout Europe produced by the first outbreak of modern science, but even the most sanguine anticipators could scarcely have looked forward to that steady, unintermitted progress which it has since maintained, nor to that succession of great discoveries which has kept up the interest of the first impulse still vigorous and undiminished. It may truly be said, that there is scarcely a single branch of physical enquiry which is either stationary or which has not been for many years past in a constant state of advance, and in which the progress is not at this moment going on with accelerated rapidity."

There is an active principle in the human mind which is elicited by excitement, but which, unmoved, is inert. As in water, so in mind. The stagnant pool soon becomes putrescent. The turbid and agitated ocean is healthful and pure. 'Tis the action of the waters that secures their purity. The diffusion of knowledge has tended to the increase of civilization and wealth. These, in turn, have given opportunity to the diffusion of taste for intellectual pursuits; and to the increased and enlarged opportunities afforded from the 16th century to the present time, we must mainly attribute the great extension of knowledge in every thing connected with science and the useful arts. Mind has been brought into competition and collision with mind. Scientific truths have been developed and tested, and brought to bear on the common affairs and business of life.

These results have been attained in all the arts and business of man. The age in which we live may emphatically, beyond all others, be said to be the age of mechanics; and much as we have progressed, we must not flatter ourselves that we have attained perfection in any of them. As much as we are beyond those who preceded us, in all probability, we shall fall behind those who succeed us. The impulse is given: the mind of man is pursuing the investigation of the useful—the knowledge of one age is transmitted to the next, and so we may increase upon increase until, the command will go forth that "Time shall be no more." Nor will the increase and development of our faculties then cease.

Adam Smith, in his "Wealth of Na-

tions," describes a philosopher as a person whose trade it is to do nothing, and speculate on every thing. If Adam Smith had lived at this day, he probably would reverse this definition; for the great, vast, and most beneficial results which have been attained, in increasing the wealth of nations, of which he wrote much and perhaps knew but little, have been thus attained by the labors of philosophers, systematically applying the principles of true science to the improvement of the Mechanic Arts. It is principles which are the objects of enquiry to the natural philosopher, and the elucidation of a truth may be completely accomplished by the most familiar and common-place facts. In truth, philosophy in modern days has descended from its stilts, and mixing in the common affairs and business of life, is, by the elucidation of its principles in a familiar manner, become the common acquaintance of all who reflect. The observation of the fall of an apple, led the immortal Newton to the discovery of gravitation, and other things, equally common and apparently trivial, have led to other important results. To the natural philosopher there is no natural object unimportant. From the last of Nature's works, the greatest lessons may be learned. The scientific mind applies principles readily to every incident as it occurs, and finds improvement and delight in the pursuit. He finds

"Tongues in trees—books in the running brooks—  
Sermons in stones, and good in every thing."

"Accustomed," says an able writer, "to trace the operations of general causes and the exemplification of general laws, in circumstances where the unformed and unenquiring eye perceives neither novelty nor beauty, he walks in the midst of wonders. Every object which falls in his way elucidates some principle—affords some instruction, and impresses him with a sense of harmony and order. Nor is it a mere passive pleasure that is thus communicated. A thousand questions are continually arising in his mind—a thousand subjects of enquiry presenting themselves which keep his faculties in constant exercise, and his thoughts perpetually on the wing, so that lassitude is excluded from his life; and that craving after artificial excitement and dissipation of mind, which leads so many into frivolous, unworthy, and destructive pursuits, is altogether eradicated from his bosom."

It may be asked, "What has all this to do with the present occasion?" The answer is, that every mechanic art is the reduction to practice of scientific principles. The carpenter or mason who lays out his building by the use of the base 6, the perpendicular 8, and the hypotenuse 10, or corresponding numbers, has the demonstration that he is laying out the building at right angles, in the 47th proposition of the first book of Euclid's elements;—the sum of the squares of the base and perpendicular being equal to the square of the hypotenuse. They, too, will more fully understand how to spring their arches and raise their girders,

by understanding the principles upon which the means used accomplish the ends intended, than in the mere copying, without reflection, the work of others. For although a theorist, without practice, would, in all probability, erect but a sorry edifice, yet where a knowledge of principles is combined with practice, the advantage is apparent to all. The tanner, in preparing his leather, is a chemist in practice—so, too, the saddler and shoemaker, even in the preparation of their wax ends, in giving proper consistency and tenacity to the materials used, independent of the philosophical principles in the shapes and forms of their work, and its adaptation to its intended purposes.

It were endless, however, to enumerate all the examples of this truth in the trades and occupations here assembled. It exists in them all, and the instances I have cited are perhaps the least striking of any that might be given.

What was it that raised David Rittenhouse, a native of Pennsylvania, above the ordinary clockmakers of the country in which he lived, and placed his name high among the learned of the world? What was it that raised Brindley, from an apprentice to a Derbyshire millwright, to one of the greatest engineers and mechanics which the world ever produced? Neither of these great men originally received more than the rudiments of an English education. It was the application of their giant minds to the study of principles that placed the one at the head of the philosophers and astronomers of his time, and made the other the companion and the adviser of the King, Lords and Commons of his native land, so that scarcely any public work was entered upon without his superintendence and advice.

And what too placed Fulton, another son of Pennsylvania, so high in the estimation of the world?—It was not his birth. It was not this world's wealth. It was the cultivation of his mighty intellect, which, but for his *reading* and *reflection*, like the diamond in the mine, might have lain obscure, unnoticed and unknown.

Oliver Evans, of Philadelphia, in his day, and that too within the recollection of him who now addresses you, was esteemed a crack-brained enthusiast, when he avowed that the child was then born, who by the force of steam should travel from Washington to New-York in a day.

His language was, "People will travel in stages moved by steam from one city to another, almost as fast as birds fly—fifteen or twenty miles an hour." "A carriage will set out from Washington in the morning, the passengers will breakfast at Baltimore, dine at Philadelphia, and sup at New-York; the same day."

The first of these assertions has been accomplished, and the second will be, before we are three years older. Yet this man, when in 1787, he petitioned the legislature of Pennsylvania for encouragement and assistance, to test the possibility of using steam as a motive power for wagons or carriages, was considered insane.

(To be concluded in our next.)

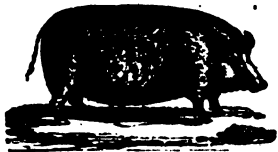

AGRICULTURE, &c.

There is no species of stock of greater importance to the agricultural interest than the hog. His flesh is the most important item in animal food; he is far more prolific than any other large domestic animal; he arrives at maturity in less time than any other, except the sheep; with half the expense, in proportion to his value; and is much less liable to disease, indeed he can scarcely be considered liable at all. And if we cannot ride him as we do the horse, milk him like the cow, or wear his clothing as we do that of the sheep, still every part of him is valuable; and the short period of his life returns us the pay for his keeping at shorter credit than any other large domestic animal. And yet there is no other animal so completely neglected. In many parts of the country, a stranger to our customs would suppose, from the treatment they receive, that they were wild animals, and that the people were at considerable expense to maintain dogs, not merely to guard against them, but to worry and destroy them. To any person of a cultivated mind, and who knows the value of the swine, it would be difficult to tell which feeling would be strongest, disgust to see the lean, raw-boned, slab-sided, and long-legged specimens, with long lop ears, which infest our streets, seeking something to keep them from starving; or abhorrence of the cruelty they suffer, in having their ears torn from their heads, by dogs trained to the business; and from whose teeth they are scarcely ever a moment secure.

I cannot help thinking the man, who sets the example of reforming this horrid neglect and ill treatment of so valuable an animal, not only by improving all its improveable points, and thereby greatly enhancing its value, but by so doing, rescuing the poor suffering animal from a state of incessant torment during the short period it is permitted to live, deserves at least the thanks of every person, who loves profit and good eating, or who hates cruelty.

Having been long and deeply impressed with such a view of the subject, it has given me extreme pleasure to examine Mr. Bement's pigs, referred to in the following communication, as I think he has arrived at, or very near, the *ne plus ultra* of improvement. Their form is improved in every point. They are small eaters, their growth is rapid, and their appearance shows that their pork must be delicious. I am confident no agriculturist, who has any pretensions to common sense, could see them without being anxious to obtain the breed.

S. BLYDENBURGH.

[From the Cultivator.]

**IMPROVED CHINA HOGS.**—Mr. Buel, Sir: Having had frequent applications, by letter, for a description of my improved breed of China hogs, I know of no better method of conveying a correct idea, unless by personal inspection, than by a likeness, which I have procured, and accompanies this.

The drawing was taken from a young sow, 9 months old, when in high condition.

This superior breed of swine, as I have observed in a former communication, was first introduced here by the late Christopher

Dunn, Esq. Some ten or twelve years since, when passing through Princeton or New-Brunswick, N. J., in the stage, his sagacious eye was attracted by a beautiful sow, with her litter of pigs, running in the street. Delighted with their appearance, he was determined to possess some of them if possible. He accordingly applied to the driver of the stage to procure a pair of them for him. As an inducement, and to insure success, he offered him the liberal price of twenty dollars, for a male and female, although only eight weeks old, on their delivery to a certain house in New-York. They were of course procured and delivered, and from these two have sprung my "*Improved China Hogs*."

Their color is various, some white, black and white spotted, and others blue and white. They are longer in body than the pure China breed. Upright or mouse-eared, small head and legs, broad on the back, round bodied, and hams well let down. Skin thin—flesh delicate and fine flavored.

They are easy keepers, and of course small consumers, quiet and peaceable in disposition, seldom roaming or committing depredations; keep in good condition on grass only.

They are not remarkable for size, seldom attaining more than 200 to 250 pounds, although instances have occurred where they have been made to reach 350! Therefore, they cannot, in their pure state, be called the "farmer's hog," but their great value is in crossing with the common hog of the country. A very good hog may be obtained by a cross with your *land shads*,—your long legged, long nosed, big-boned, thin backed, slab-sided, hungry, ravenous, roaming tormentors, that will run squeaking about the yard with an ear of corn in their mouths.

To give you some idea in what estimation they are held by persons who have procured them of me, I have taken the liberty of making the following extracts from some of their letters.

"My Chinas, the true Bement breed, exceed all praise; you never saw their equals. I have a young boar in the pen, nine months old, that I will show against the United States, out of the boar and sow I had of you, both of which I still keep. Nothing can compare with them in this country, and I honestly assure you, I never saw their equals any where, for all needful qualities in the hog."

"Dear sir—I have the satisfaction of saying to you, that I got my little Berkshire and China home in good order, and doing finely, and are much admired by every person who sees them. Should I meet with success in rearing from this pair, shall not be able to furnish any thing like the quantity spoken for."

In another letter a valuable correspondent says—"The hogs I had of you have done admirably, and I am getting a fine stock of them; but on the whole, I like the full bred improved China better than the cross, and I am getting back into the pure blood. The young sows, of which I have three from the white (Hosack) boar you had, have had pigs from the old boar, but they are not true enough in blood, appearance, and shape, to suit me; whereas the mother, who is the true China, brings the pigs from the old boar, both in color, shape, size and every thing, as if they were cast in the same mould,—and that is what I like,—uniformity of appearance, even in hogs, and this boar, let me tell you, has the admiration of all who have seen him, as the best and most perfect hog in the country. These hogs, 'tis true, are not large, they are indeed rather small; but they are the easiest kept of any according to their size, that I ever saw, and so far as I have yet seen, I prefer them,

even to the Bedfords, or any I know. The Bedfords are good, but they are too heavy headed, long legged, and great eaters, to suit me altogether. The quiet, peaceable dispositions of the Chinas, like that of the short horn cattle, is a great item, I assure you, in a farmer's account."

I might fill a page with similar extracts, but I think it unnecessary, for I shall not be able to supply all my orders until next spring.

In the next No. I propose to furnish you with a portrait of one of the Berkshire breed, of which I am now in possession, imported by S. Hawes, in 1832.

C. N. BEMENT.

Albany, Sept. 1, 1835.

[From the Cultivator.]

**ON THE UTILITY AND BEST METHOD OF COOKING FOOD FOR DOMESTIC ANIMALS.**—This subject has engaged the attention of practical men in Europe and in this country for many years, and it is a branch of rural economy at all times worthy the careful investigation of the farmer. The Highland Society of Scotland have, in a particular manner, directed the public attention to the comparative advantages of feeding farm-stock with prepared or unprepared food, and have, by liberal premiums, induced numerous experiments to be accurately made, and elicited much valuable information. The conclusions which have been drawn from these and other experiments, seem to be,—

1. That a great saving, some say one half or more, is effected by cutting the dry fodder for horses and neat cattle, and feeding it with their provender or grain, in two or three daily messes, in mangers. Not that the food is thereby enhanced in its inherent properties, but that given in this way it all tells—is all consumed, all digested, all converted into nutriment. There is comparatively none wasted, or voided, without having benefitted the animal. In the ordinary mode of feeding in racks, yards, and in open fields at stacks, it is well known that much is lost, from the difficulty of masticating uncut hay, straw and stalks, and from its being trodden under the feet of animals and spoilt. Much labor is besides saved to the animal, as cut food requires less mastication, and the animal enjoys a longer period of rest.

2. That grain and pulse, as cattle food, is enhanced in value by being ground or bruised before it is fed out, so much as to warrant the expense of sending it to mill, and the deduction of toll. Indian corn, oats, rye, and other grain, given to farm animals in a dry, unbroken state, it must have been observed by every one, particularly when the animal is high fed, are often voided in a half or wholly undigested state, and are virtually lost. This does not happen when the grain has been ground.

3. That although roots, as ruta бага, mangel wurzel and potatoes, are improved as fattening materials for neat cattle, by cooking, the advantages hardly counterbalance the extra expense of labor and fuel.

4. That for working horses, cooking the roots we have enumerated, and feeding them with cut hay and straw, is of manifest advantage; and that thus fed, they supersede the necessity of grain.

5. That in fattening hogs, there is decided economy in grinding and cooking the food. The experiments upon this subject are many and conclusive. Some estimate the saving at one half the quantity of food. Taking into account the various materials on a farm, which may thus be turned to account, we are satisfied that one half the cost

of making pork may in this way be saved. Swine are voracious animals, and will eat more than their stomachs can digest, unless assisted by the cooking process. There are upon the farm many refuse matters, as pumpkins, squashes, small potatoes, early and defective apples and apple pomace, which are of little value, except as hog food, but which, if well husbanded, cooked and mixed with ground provender, contribute essentially to cheapen our pork. It has been questioned whether the articles we have enumerated are nutritive to pigs, when given in their raw state; while all admit, who have made the experiment, that they are highly so when cooked. Cooking undoubtedly adds to their nutritive properties, as it does to the nutritive properties of Indian meal.

Before we offer our views of the most economical mode of cooking food for hogs, and of the apparatus to be employed, we beg leave to submit the plan of a hog pen or piggery, which, with some modifications, is the model of one we examined at the Shaker village in Niskeuna.

Fig. 1.

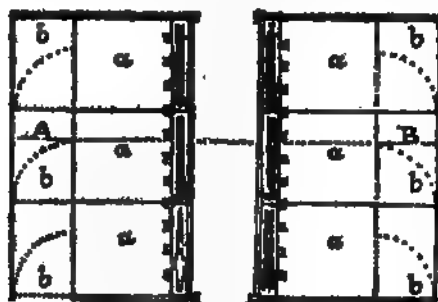

Fig. 1, exhibits a ground plan of the building, showing a gangway in the centre, with a range of pens on each side. The breadth is 28 feet, and the length may be adapted to the convenience of the builder. The pens are six feet broad and ten feet deep, with a cross partition four feet from the rear, and a four feet door, which is used to close the passage between the front department, (a) and the department b, or to extend the partition between the pens. The different uses of the doors are shown on the two sides in the cut. The pens are calculated for four hogs each, and the section here exhibited will therefore accommodate 24. When the pens require to be cleaned, the doors are shut into the cross partitions, as at A, so that the rear presents an uninterrupted passage; the hogs being confined in a; and as soon as the pens are cleaned, these doors are thrown back as at B. The troughs are embraced in the gangway.

Fig. 2, shows a cross section along the dotted line A B. The partitions are three and a half feet high, the posts eleven feet, giving seven feet to the basement, and four to the upper story, below the roof. The position of the feeding troughs is here shown. They are provided with lids, hung with stout hinges above, and may be let down so as to exclude the hogs from the troughs while they are being cleaned or replenished with food, or raised up, at pleasure, as shown in this section. Each lid is provided with an iron bolt, (fig. 4,) which works in staples, and confines the lid in the position required. This section also shows the slope of the floor in b b, so constructed that the urine may drain off. The dotted lines represent the size of the building, when, instead of the apartment b b, it is wished to let the hogs run in an open yard. For small farmeries, a single range of pens and the gangway may suffice. The loft serves as a store room for hog food, &c.

Fig. 2.

Fig. 3, is a section along C D, showing the studs that prevent the interference of the hogs while eating.

The boiling or steaming room is in one end of the building, and communicates with the passage and the loft.

The peculiarities, or rather the advantages of this piggery, consist in the facility which is afforded of cleaning the pens and the troughs, and of depositing the food in the latter, without being incommoded by the hogs, and in preventing the hogs worrying each other.

We shall now exhibit the model of a steaming apparatus, calculated for a large establishment. We have shown the plan to an intelligent master in one of our furnaces, who estimates the cost of boiler, pipes, and cocks, at \$50.

"A is a barrel or other vessel for containing water and supplying it to the boiler C. D is a safety valve. At the upper part of the boiler at C are placed two tubes, with stop cocks. One of these tubes terminates near the bottom of the boiler. Upon the stop cock being turned, water should always issue from this tube. When, therefore, steam issues from it, and not water, this indicates that the water is too much boiled away, and consequently that there is a deficiency of water in the boiler. The other tube terminates within the boiler, near the top. Upon the stop cock being turned, therefore, steam ought always to issue forth. But should water in place of steam come out, then it will appear that the boiler is too full of water. In this manner the attendant, by turning either stop cock, ascertains whether there is a deficiency or excess of water in the boiler. The quantity of water could indeed be regulated by other means; but that described will be found sufficient in practice. F is the furnace, and E is a pipe with a stop cock communicating with the boiler. When it is wished to obtain hot water, it is obtained by this pipe. A pipe G communicates with the barrels H, I, K, and conveys the steam to them; and in these is placed the food to be steamed. By means of the stop cocks L, L, the communication can be cut off with any of the barrels, so that the steam may be admitted to one barrel or two barrels, or three, as may be wished. The barrels in the figure are three, but the number may be extended. Each barrel has a moveable lid, which is kept down by screws, and a sliding board below, by which the food, when ready, is withdrawn. The barrels are raised on a frame, so that a wheel barrow or vat may be placed below, and the food at once emptied into it."

"By means of an apparatus of this kind, roots and other parts of plants may be

steamed in a convenient and economical manner."

[Fig. 5.]

The relative advantages of steaming and boiling will very much depend, we suspect, on the extent of the establishment. We have tried both, though our steamer was imperfect; and have come to the conclusion, that when the number of hogs to be supplied does not exceed 15 or 20, boiling is preferable,—as with a good boiler, of the capacity of 30 gallons, from 12 to 16 barrels of food may be easily cooked in a day. But much depends on the judicious setting of the boiler, so that it may receive the whole advantage of the fire. For this purpose the brick work should be made to conform to the shape of the kettle, leaving a space of three or four inches between them, until it reaches nearly the top of the kettle, where a tier of brick set edgewise is projected for the flange of the boiler to rest upon; and the bottom of the fire flue should be above the bottom of the kettle, or about parallel with the commencement of the slope which rounds its bottom. By this means, the flame is thrown upon the sides and bottom, and in a manner that the whole boiler is cooled with it on its passage to the smoke flue; and the brick work being heated constantly refracts back its heat upon the boiler. A tight cover should be laid over the cooking food, to prevent the free escape of the steam, by partially confining which, the cooking process is greatly facilitated.

There should be appended to the hog house an open yard, for straw, litter, weeds, &c., which the hogs, during summer, will work into manure, and into which the dung is thrown from the pen.

Hogs are subject to various diseases, particularly if shut up in a close pen, during the time of fattening, which are often suddenly fatal. Prevention is here easier than cure; and many farmers prefer giving their hogs yard room, where they can root in the earth, which is deemed a preventive. Others give them occasionally rotten wood, charcoal, sulphur, antimony or madder, all which are considered as aperients, cleansers or alteratives, and consequently as conducing to health. Salt is all important, and should be habitually blended with their cooked food.

NEW-YORK, AMERICAN.

SEPTEMBER 26—OCTOBER 2, 1836.

LITERARY NOTICES.

THE GIFT, a Christmas and New Years' present, 1836, edited by Miss LESLIE: Philadelphia, E. L. CAREY & A. HART.—A new Annual, very prettily got up, as the phrase is, in externals and about an average in intellects. The "unpretending Mr. Hudson," by Miss Sedgewick, is very good. The Serenade, by the Editor, very so-so. The sketch of an unwritten drama, of Lord Byron's, communicated by Washington Irving, is worth copying.

AN UNWRITTEN DRAMA OF LORD BYRON.

By Washington Irving.

The reading world has, I apprehend, by this time, become possessed of nearly every scrap of poetry and romance written by Lord Byron. It may be pleasant, however, to know something of a dramatic poem, which he did not write, but which he projected—and this is the story.

The hero, whom we will call Alfonso, is a Spanish nobleman, just entering upon the career of life. His passions, from early and unrestrained indulgence, here become impetuous and ungovernable, and he follows their impulse with a wild and heedless disregard of consequences.

Soon after his entrance into the world, he finds himself followed, occasionally, in public places, by a person masked and muffled up, so as to conceal both countenance and figure. He at first pays but little attention to the circumstance, considering the stranger some idle or impertinent loungee about society. By degrees, however, the frequent intrusion of this silent and observant follower, becomes extremely irksome. The mystery, too, which envelops him, heightens the annoyance. Alfonso is unable to identify him with any of his acquaintance, his name, his country, his place of abode, is all unknown, and it is impossible even to conjecture his motives, for his singular espionage. It is carried, by degrees, to such lengths, that he becomes, as it were, Alfonso's shadow, his second self. Not only the private actions of the latter passed under the scrutiny of this officious monitor, but his most secret thoughts seem known to him. Speak of him, he stands by his side; think of him, he feels his presence, though invisible, weigh upon his spirits, like a troubled atmosphere, waking or sleeping, Alfonso has him in thought or in view. He crosses his path at every turn; like the demon in Faust, he intrudes on his solitude. He follows him in the crowded street, or in the brilliant saloon; thwarting his schemes, and marring all his intrigues of love or ambition. In the giddy mazes of the dance, in which Alfonso is addressing his fair partner with the honeyed words of seduction, he sees the stranger pass like a shadow before him—a voice, like the voice of his own soul, whispers in his ear—the words of seduction die from his lips—he no longer hears the music of the dance.

The hero of the drama becomes abstracted and gloomy. Youth, health, power, wealth, all that promised to give zest to life, have lost their charm. The sweetest cup of pleasure becomes poison to him; existence is a burthen. To add to his despair, he doubts the fidelity of the fair, but frail object of his affection, and suspects the unknown to have supplanted him in her thoughts.

Alfonso now thirsts only for vengeance, but the mysterious stranger eludes his pursuit, and his emissaries in vain endeavor to discover his retreat. At length he succeeds in tracing him to the house of his mistress, and attacks him with the fury of frantic jealousy, taxes him with his wrongs, and demands satisfaction. They fight, his rival scarcely defends himself, at the first thrust, he receives the sword of Alfonso in his bosom; and in falling exclaims, "are you satisfied?"

The mask and mantle of the unknown drop off, and Alfonso discovers his own image,—the spectre of himself,—he dies with horror.

The spectre is an allegorical being, the personification of conscience, or the passions.

Such was the general plan of a poem which Lord Byron had in mind several years since; and which he communicated, in conversation to Captain Medwin, from whom I received it nearly in the foregoing words. The idea was taken from a Spanish play, called the Embozado, or Encapotado, which

signifies a person muffled or disguised, and was furnished to Byron by Shelley, as his Lordship did not understand Spanish. The foregoing plan is evidently vague and immature, and would doubtless have undergone many modifications in the progress of being brought out. Lord Byron intended to treat it in the genuine spirit of Goethe, as displayed in his wild and extraordinary drama of Faust, and expected to make it very effective. It certainly afforded ample scope for the mystic, the misanthropic, the metaphysical and the romantic, in which he so much delighted, and would have given him an opportunity of interweaving much of his own peculiar feelings and experience.

How far the plan he had in view agreed with the Spanish original, I have not been able to ascertain. The latter was said to be by Calderon; but it is not to be found in any edition of his works that I have ever seen. My curiosity being awakened on the subject, I made diligent inquiry, while in Spain, for the play in question, but it was not to be met with, in any of the public libraries, or private collections; nor could the booksellers give me any information about it. Some of the most learned and indefatigable collectors of Spanish literature informed me that a play of that kind, called the Embozado of Cordova, was somewhere in existence, but that they had never seen it. The foregoing sketch of the plot may hereafter suggest a rich theme to a poet or dramatist of the Byron school.

PARLEY'S MAGAZINE, vols. 1 and 2, and parts 9 and 10: Boston, SAMUEL COLMAN, successor to Lilly, Wak & Co. N. Y: COLLINS & HANNAY, and J.P. CALLENDER.—We have here a new edition revised and improved of this amusing and instructive miscellany for children. It is now published in numbers very prettily put up, which together make an annual volume of which the cost is only one dollar! Among the recent improvements is that of introducing short pieces of music, furnished for the work by Messrs. Mason & Webb, professors in the Boston Academy of Music.

The general aim of this Magazine, by previous notices, our readers are apprised, is to make a miscellany for children, which shall be attractive at once, instructive and useful—avoiding controversial subjects, and relying as much as possible on original matter.

The wood-cuts are very well done—one, which is the frontispiece of part 10, struck us particularly. It represents blind children making baskets—and is very natural and spirited. We copy, as a fair specimen of the manner in which subjects generally are treated, the notice referring to this cut.

SCHOOL FOR THE BLIND.—Perhaps some of my readers do not even know that there is an Institution for the Blind in Boston. If there are any such, I think they will be very glad to hear about it. It is situated in Pearl street. The buildings was formerly a dwellinghouse; and was given by the owner, on purpose for a schoolhouse and workhouse for the blind. On the side of it towards the street, you may see, in large letters, the following:

INSTITUTION  
FOR THE BLIND.  
THIS EDIFICE  
PRESENTED BY  
THOMAS H. PERKINS  
MDCCCXXXIII.

The school was first opened in 1832, in Pleasant Street, with only six pupils. The next year Mr. Perkins having made them a present of his house, and large sums of money having also been given them in many of our cities and towns, the school was removed to Pearl Street, where it now is.—In 1834, they had 34 pupils. In 1835—this year—the number had increased to more than 40; and a great many more would be glad to attend, if they had room for them. I understand they are about to enlarge the building, for this very purpose.

The pupils are not all of them boys; there are nearly as many girls as there are boys. You would be amused to visit them, and see what they could do. Why, they learn to spell, and read, and write, and sing, and work. They print too: that is, they print their own books. I suppose you will wonder how they can read, when they are blind.

The letters are made, not with ink, but by pressing the paper, while it is wet, so that the letters stand up in ridges, very large; and they can tell what they are, by passing their fingers across the lines. Some pupils who have been in the Institution a long time, will read almost as fast as you or I can. They have maps, too, and learn geography. The mountains are raised in ridges, and the rivers are hollowed or depressed lines. The towns are square, or lots.

But what sort of work can they do? you will ask. A great many sorts. The girls can sew, knit, braid, and set the types for printing; and the boys can make door-mats cushions, mattresses, and willow baskets. Some of their door-mats are woven.—You may almost always, when you go there, see one blind man weaving. The grass—Manilla grass, they call it—which he uses, is of various colors; and yet he will arrange the different colors so as to have the mat checkered the proper manner, nearly as well as if he could see. Not that he can tell different colors by feeling—except red, which he says feels more harsh than other colors; but he has a particular box or shelf on which grass of each different color is laid, and he seldom makes a mistake.

You would be surprised to see how happy they are, especially the boys who make baskets. But you may see how they look, when at this sort of work, by noticing the picture on the preceding page; which was drawn by one of our best artists, after being on the spot and seeing them for himself.

In the next number, or next but one, I shall say more about the Institution, for it is one of the most interesting in the whole city of Boston. They have an exhibition once a fortnight. There will be one in a few days; and I shall attend it; and afterwards tell you what they do.

MEMOIRS OF GREAT COMMANDERS: by G. P. R. JAMES, author of Richelieu, &c., 2 vols. Philadelphia: E. L. CAREY and A. HART.—Mr. James has collected and embodied very interesting lives of some very interesting men; though, so far as we have glanced at some of the biographies, their details seem mostly those already known. The notices are, however, well put together, and sufficiently copious to enable readers to form a right judgment of each commander. The writer does not withhold his own opinion of the character of those whose actions he commemorates, and of Gen. Monk, whose biography is one of the best executed in these volumes, he thus speaks:

The violent parties which were born of the civil wars, viewed the conduct of Monk in the most opposite aspects; nor was it alone those two factions, which would have excluded the King, or shackled his return with unworthy conditions, which either misrepresented General Monk's actions or imputed to him evil motives, or depreciated his talents.

Those persons who had concurred in the Restoration, hated him who had effected it with the violence of rivalry, strove to invalidate his claims, in order to enhance their own, and envied him the rewards which they had neither merited nor obtained. Thus the disappointed Cavalier, the thwarted Presbyterian, the crushed Republican, are alike found slighting Monk's abilities and denying his merit. Bishop Burnet himself, with the violent party-feeling which overcame in him sometimes both an excellent judgment and a strong love of truth, has spoken lightly of Monk's understanding. But in the very writings of the men who would condemn him, we find the highest tribute to his character. If we take but the facts which they state, and put aside the prejudices with which they comment on them, we shall perceive that Monk distinguished himself highly in early life, and won the esteem of both parties in the State, when both were prolific in men of great and extraordinary genius. We shall find that he was eminently successful against the greatest officer the Dutch ever produced—that in his command in Scotland he reduced a turbulent, dissatisfied, and irritated population, to quietude and order; and did so by means which at once compelled their obedience, obtained their respect, and won their love—that in a most difficult and extraordinary time he acted with consummate prudence, skill, and firmness, repressed insurrections, guided the obstinate, governed the unruly, intimidated the fierce, overawed the bold, and without the effusion

of a drop of blood, conducted a total revolution in thoughts, feelings, policy, and government, to a safe and speedy termination.

A man may perchance gain one victory, or more—increase his wealth, or raise himself in station, by a mere concatenation of fortunate circumstances; but a man cannot go through a long and complicated enterprise, where many are opposed to him, and all are jealous of him, where he has frequently to change his conduct without changing his object, where he has to take advantage of some circumstances and create others, without many of those qualities of mind which constitute a great man.

Monks did so, and he was a great man. Nor can it be said that he was ungenerous, though the rewards which he obtained made many envious, and the wealth he acquired offered a fair excuse for party accusation. His admission of the King, without making any terms for himself, was either an act of noble feeling or of policy. If of noble feeling it speaks for itself; and if of policy, it was that of generous policy which none could conceive or appreciate but a generous heart. Taken by itself, it was a fine and magnificent action, and as such will be remembered when the politics of those times are forgotten, and prejudices are no more.

**THE EARLY NAVAL HISTORY OF ENGLAND**, by ROBERT SOUTHNEY, L.L.D., Poet Laureate. 1 vol. Philadelphia, CAREY, LEA & BLANCHARD.—The most vigorous, accurate, and copious prose writer of the age, here puts his hand to a work which—written in the spirit that pervades it—will both improve and instruct.

They who have read "the Life of Nelson," from the same pen, will not need any other inducement, to turn to this volume on a somewhat cognate theme, and the rather, as here, there is less temptation to gloss over moral obliquities, than in writing the life of one, then scarcely eclipsed from the scene of his splendor—and some of whose acts, especially the murder of *Caraccioli* in the bay of Naples, became so identified with the impassioned politics of the day, as to render calm and impartial judgment very difficult.

This history begins with the invasion of Britain by *Julius Cæsar*, and is brought down to the close of the fourteenth century—a period embracing much that will necessarily interest all inquirers into the commencements and early feats, of the greatest naval Power the world has yet seen.

We shall still further tempt readers, we think, by copying entire the author's own exposition of the object of his work. Here it is:

According to the Welsh Triads, the earliest name by which Britain was known was *Clas Merdin*, the sea-defended green spot. Such an appellation may seem to have been prophetic. But the sea defends no people who cannot defend themselves; and it was with this feeling that Wordsworth, the great poet of his age, poured forth a lofty strain, when, looking from a valley near Dover towards the coast of France, and "the span of waters" which separated us from that then most formidable neighbor (for it was while Buonaparte was in the plenitude of his power,) he said—

"Even so doth God protect us, If we be  
Virtuous and wise! Winds blow, and waters roll,  
Strength to the brave, and Power, and Delty;  
Yet in themselves are nothing! One decree  
Spake laws to them, and said, that by the soul  
Only, the nation shall be great and free."

With all the ports of the continent in his possession, and all its natives at his command, that narrow channel was found impassable by the most ambitious, the most powerful, the most enterprising, and the most inveterate enemy with whom this nation ever was engaged in war; for Great Britain had manfully won and victoriously maintained the dominion of the sea. It will be neither an unworthy nor a useless task for an Englishman who loves his country, and who, in doing his duty towards it in his station, trusts that he may deserve to be held in remembrance by posterity, to record the actions of those brave men by whom that dominion was acquired: and a series of their lives ("wherein," to use the words of a wise and good man, "I intend to do them right with the truth thereof, and myself with the freedom") will be the most convenient form for a compendious naval history of England.

It is, however, no wish of the writer that the work he has thus undertaken should be the cause of inducing any hopeful youth, who otherwise might not have been so inclined, to enter the naval service; the ways of that service are as little ways of pleasantness as its paths are paths of peace; and rather would he that his right hand should forget its cunning than that his writings should produce such an effect. Nevertheless, as for that profession, with all its deterrents and its moral dangers, adventurers never will be wanting, so long as, in the order of Providence, such means of national defence are needful,—it is good that they should be provided with a manual of this kind, wherein, as in a chart, they may discern what they are to seek and what to shun, by perceiving what things in the conduct of their predecessors ought to be regarded as warnings, and what as examples. And as every way of life, from the highest to the humblest, has its besetting sins, so, let it be remembered, each may and ought to have its appropriate virtues; and those which the seamen is called upon to practise are of a high order. He lives in a course of privations, self-denial, and strict obedience, always in insecurity, often in danger, not seldom in the face of death. Through such discipline no man can pass unchanged; he must be brutalized by it, or exalted; it will either call forth the noble qualities of his nature, or worsen a bad disposition, and harden an evil heart. The more necessary is it, therefore, that he should be taught where to look for examples, and where for assistance and support: the former are afforded him by history, which is always most useful when it is related with most fidelity; for the latter he must look to that Heavenly Father who has created and preserved him, and in His infinite mercy has given him the means of grace.

Sailors are taught in their part of our incomparable Liturgy to pray that they may be a safeguard to the sovereign and dominions, and a security to such as pass on the seas upon their lawful occasions. They are required, before a battle, to call upon the Lord, and entreat Him "who sitteth on the throne, judging right," to "take the cause into his own hand, and judge between them and their enemies;" and they are enjoined, after the victory has been given them, to acknowledge that He has been their strength, and to pray that "the mercies which they have received at His hands may be improved to his glory, to the advancement of His gospel, the honor of their sovereign, and, as far as in them lieth, to the good of all mankind." Thus solemnly are they instructed; and it is not presumptuous to believe, that while the service is carried on in this spirit, and in this faith, the protection which has hitherto been vouchsafed it, and which is thus implored, will never be withdrawn.
